Lemma 13.46.16. *Let $k \in \mathbb{N}$. Let $a_1, a_2, \ldots, a_k$ be k integers. Let $b_1, b_2, \ldots, b_k$ be k integers. Assume that*

$$a_j \geq b_j \qquad \text{for each } j \in \{1, 2, \ldots, k\} .$$

Assume furthermore that $\sum_{j=1}^k a_j \leq \sum_{j=1}^k b_j$. Then, $a_j = b_j$ for each $j \in \{1, 2, \ldots, k\}$.

Proof of Lemma 13.46.16. Lemma 13.46.16 is obtained from Lemma 13.46.15 upon renaming the variables p and i as k and j. Thus, Lemma 13.46.16 follows from Lemma 13.46.15. □

The next few lemmas use the so-called *Iverson bracket notation*:

Definition 13.46.17. For every assertion $\mathcal{A}$, we let $[\mathcal{A}]$ denote the integer $\begin{cases} 1, & \text{if } \mathcal{A} \text{ is true;} \\ 0, & \text{if } \mathcal{A} \text{ is false} \end{cases}$.

Lemma 13.46.18. *Let $q \in \mathbb{N}$ and $r \in \mathbb{N}$ be such that $r \leq q$. Then, $\sum_{j=1}^q [j \leq r] = r$.*

Proof of Lemma 13.46.18. We have $0 \leq r \leq q$. Hence,

$$\sum_{j=1}^q [j \leq r] = \sum_{j=1}^r \underbrace{[j \leq r]}_{\substack{=1 \\ \text{(since } j\leq r)}} + \sum_{j=r+1}^q \underbrace{[j \leq r]}_{\substack{=0 \\ \text{(since we don't have } j\leq r \\ \text{(since } j\geq r+1>r))}} = \sum_{j=1}^r 1 + \underbrace{\sum_{j=r+1}^q 0}_{=0} = \sum_{j=1}^r 1 = r \cdot 1 = r.$$

This proves Lemma 13.46.18. □

Lemma 13.46.19. *Let $p \in \mathbb{N}$ and $q \in \mathbb{N}$. Let $A = (a_{i,j})_{1 \leq i \leq p,\ 1 \leq j \leq q} \in \{0,1\}^{p \times q}$ be a $\{0,1\}$-matrix. Let $(\lambda_1, \lambda_2, \ldots, \lambda_p)$ be the row sums of A. Let $(\mu_1, \mu_2, \ldots, \mu_q)$ be the column sums of A. Then:*

(a) *We have $\lambda_i = \sum_{j=1}^{q} a_{i,j}$ for each $i \in \{1, 2, \ldots, p\}$.*
(b) *We have $\mu_j = \sum_{i=1}^{p} a_{i,j}$ for each $j \in \{1, 2, \ldots, q\}$.*
(c) *We have $\sum_{i=1}^{p} \lambda_i = \sum_{j=1}^{q} \mu_j$.*
(d) *We have $\min\{\lambda_i, k\} \geq \sum_{j=1}^{k} a_{i,j}$ for each $k \in \{0, 1, \ldots, q\}$ and $i \in \{1, 2, \ldots, p\}$.*
(e) *We have $\sum_{i=1}^{p} \min\{\lambda_i, k\} \geq \sum_{j=1}^{k} \mu_j$ for each $k \in \{0, 1, \ldots, q\}$.*
(f) *If $\left(\sum_{i=1}^{p} \min\{\lambda_i, k\} = \sum_{j=1}^{k} \mu_j \text{ for each } k \in \{1, 2, \ldots, q\}\right)$, then $A = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$.*

Proof of Lemma 13.46.19. We have $(a_{i,j})_{1 \leq i \leq p,\ 1 \leq j \leq q} = A \in \{0,1\}^{p \times q}$. Thus, $a_{i,j} \in \{0,1\}$ for each $i \in \{1, 2, \ldots, p\}$ and $j \in \{1, 2, \ldots, q\}$. Hence, for each $i \in \{1, 2, \ldots, p\}$ and $j \in \{1, 2, \ldots, q\}$, we have

$$a_{i,j} \geq 0 \qquad (\text{since } a_{i,j} \in \{0,1\}) \tag{13.46.54}$$

and

$$a_{i,j} \leq 1 \qquad (\text{since } a_{i,j} \in \{0,1\}) . \tag{13.46.55}$$

(a) Recall that $(\lambda_1, \lambda_2, \ldots, \lambda_p)$ is the row sums of A. By the definition of "row sums", this means that for each $i \in \{1, 2, \ldots, p\}$, the number λ_i is the sum of all entries in the i-th row of A. Thus, for each $i \in \{1, 2, \ldots, p\}$, we have

$$\lambda_i = \left(\text{the sum of all entries in } \underbrace{\text{the } i\text{-th row of } A}_{\substack{=(a_{i,1}, a_{i,2}, \ldots, a_{i,q}) \\ (\text{since } A = (a_{i,j})_{1 \leq i \leq p,\ 1 \leq j \leq q})}} \right)$$
$$= (\text{the sum of all entries in } (a_{i,1}, a_{i,2}, \ldots, a_{i,q})) = a_{i,1} + a_{i,2} + \cdots + a_{i,q} = \sum_{j=1}^{q} a_{i,j}.$$

This proves Lemma 13.46.19(a).

(b) The proof of Lemma 13.46.19(a) can easily be adapted (mutatis mutandis) to yield a proof of Lemma 13.46.19(b).

(c) Comparing

$$\sum_{i=1}^{p} \underbrace{\lambda_i}_{\substack{=\sum_{j=1}^{q} a_{i,j} \\ (\text{by Lemma 13.46.19(a)})}} = \underbrace{\sum_{i=1}^{p} \sum_{j=1}^{q}}_{=\sum_{j=1}^{q} \sum_{i=1}^{p}} a_{i,j} = \sum_{j=1}^{q} \sum_{i=1}^{p} a_{i,j}$$

with

$$\sum_{j=1}^{q} \underbrace{\mu_j}_{\substack{=\sum_{i=1}^{p} a_{i,j} \\ (\text{by Lemma 13.46.19(b)})}} = \sum_{j=1}^{q} \sum_{i=1}^{p} a_{i,j},$$

we obtain $\sum_{i=1}^{p} \lambda_i = \sum_{j=1}^{q} \mu_j$. This proves Lemma 13.46.19(c).

(d) Let $k \in \{0, 1, \ldots, q\}$ and $i \in \{1, 2, \ldots, p\}$. Lemma 13.46.19(a) yields $\lambda_i = \sum_{j=1}^{q} a_{i,j}$. But

$$\sum_{j=1}^{k} \underbrace{a_{i,j}}_{\substack{\leq 1 \\ (\text{by (13.46.55)})}} \leq \sum_{j=1}^{k} 1 = k \cdot 1 = k.$$

Furthermore, $k \in \{0, 1, \ldots, q\}$, so that $0 \leq k \leq q$. Hence,

$$\sum_{j=1}^{q} a_{i,j} = \sum_{j=1}^{k} a_{i,j} + \sum_{j=k+1}^{q} \underbrace{a_{i,j}}_{\substack{\geq 0 \\ (\text{by (13.46.54)})}} \geq \sum_{j=1}^{k} a_{i,j} + \underbrace{\sum_{j=k+1}^{q} 0}_{=0} = \sum_{j=1}^{k} a_{i,j},$$

so that

$$\sum_{j=1}^{k} a_{i,j} \leq \sum_{j=1}^{q} a_{i,j} = \lambda_i .$$

But let us recall the following basic fact about integers: If three integers α, β, γ satisfy $\alpha \leq \beta$ and $\alpha \leq \gamma$, then $\alpha \leq \min\{\beta, \gamma\}$. Applying this fact to $\alpha = \sum_{j=1}^{k} a_{i,j}$, $\beta = \lambda_i$ and $\gamma = k$, we conclude that $\sum_{j=1}^{k} a_{i,j} \leq \min\{\lambda_i, k\}$ (since $\sum_{j=1}^{k} a_{i,j} \leq \lambda_i$ and $\sum_{j=1}^{k} a_{i,j} \leq k$). In other words, $\min\{\lambda_i, k\} \geq \sum_{j=1}^{k} a_{i,j}$. This proves Lemma 13.46.19(d).

(e) Let $k \in \{0, 1, \ldots, q\}$. Now,

$$\sum_{i=1}^{p} \underbrace{\min\{\lambda_i, k\}}_{\substack{\geq \sum_{j=1}^{k} a_{i,j} \\ \text{(by Lemma 13.46.19(d))}}} \geq \underbrace{\sum_{i=1}^{p} \sum_{j=1}^{k}}_{= \sum_{j=1}^{k} \sum_{i=1}^{p}} a_{i,j} = \sum_{j=1}^{k} \underbrace{\sum_{i=1}^{p} a_{i,j}}_{\substack{= \mu_j \\ \text{(by Lemma 13.46.19(b))}}} = \sum_{j=1}^{k} \mu_j .$$

This proves Lemma 13.46.19(e).

(f) Assume that

$$\left(\sum_{i=1}^{p} \min\{\lambda_i, k\} = \sum_{j=1}^{k} \mu_j \text{ for each } k \in \{1, 2, \ldots, q\} \right) . \tag{13.46.56}$$

We want to show that $A = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$.

Let $k \in \{1, 2, \ldots, q\}$. Thus, $k \in \{1, 2, \ldots, q\} \subset \{0, 1, \ldots, q\}$. But (13.46.56) yields

$$\sum_{i=1}^{p} \min\{\lambda_i, k\} = \sum_{j=1}^{k} \underbrace{\mu_j}_{\substack{= \sum_{i=1}^{p} a_{i,j} \\ \text{(by Lemma 13.46.19(b))}}} = \underbrace{\sum_{j=1}^{k} \sum_{i=1}^{p}}_{= \sum_{i=1}^{p} \sum_{j=1}^{k}} a_{i,j} = \sum_{i=1}^{p} \sum_{j=1}^{k} a_{i,j} \leq \sum_{i=1}^{p} \sum_{j=1}^{k} a_{i,j} .$$

Furthermore, we know that $\min\{\lambda_i, k\} \geq \sum_{j=1}^{k} a_{i,j}$ for each $i \in \{1, 2, \ldots, p\}$ (by Lemma 13.46.19(d)). Hence, Lemma 13.46.15 (applied to $\min\{\lambda_i, k\}$ and $\sum_{j=1}^{k} a_{i,j}$ instead of a_i and b_i) shows that

$$\min\{\lambda_i, k\} = \sum_{j=1}^{k} a_{i,j} \qquad \text{for each } i \in \{1, 2, \ldots, p\} . \tag{13.46.57}$$

Now, forget that we fixed k. We thus have proven (13.46.57) for each $k \in \{1, 2, \ldots, q\}$.

Now, pick $i \in \{1, 2, \ldots, p\}$. We shall show that

$$a_{i,k} \geq [k \leq \lambda_i] \qquad \text{for each } k \in \{1, 2, \ldots, q\} . \tag{13.46.58}$$

[*Proof of (13.46.58):* Let $k \in \{1, 2, \ldots, q\}$. We must prove the inequality $a_{i,k} \geq [k \leq \lambda_i]$.

Indeed, we are in one of the following two cases:

Case 1: We have $k \leq \lambda_i$.

Case 2: We don't have $k \leq \lambda_i$.

Let us first consider Case 1. In this case, we have $k \leq \lambda_i$. Thus, $[k \leq \lambda_i] = 1$. Also, $k \geq 1$ (since $k \in \{1, 2, \ldots, q\}$), so that $k \in \{1, 2, \ldots, k\}$. But from $k \leq \lambda_i$, we also obtain $\min\{\lambda_i, k\} = k$. Thus,

$$\sum_{j=1}^{k} 1 = k \cdot 1 = k \leq k = \min\{\lambda_i, k\} = \sum_{j=1}^{k} a_{i,j}$$

(by (13.46.57)). Furthermore, $1 \geq a_{i,j}$ for each $j \in \{1, 2, \ldots, k\}$ [538]. Hence, Lemma 13.46.16 (applied to 1 and $a_{i,j}$ instead of a_j and b_j) shows that $1 = a_{i,j}$ for each $j \in \{1, 2, \ldots, k\}$. Applying this to $j = k$, we obtain $1 = a_{i,k}$ (since $k \in \{1, 2, \ldots, k\}$). Hence, $a_{i,k} = 1 = [k \leq \lambda_i]$, so that $a_{i,k} \geq [k \leq \lambda_i]$. Thus, the inequality $a_{i,k} \geq [k \leq \lambda_i]$ is proven in Case 1.

[538] *Proof.* Let $j \in \{1, 2, \ldots, k\}$. Then, $j \in \{1, 2, \ldots, k\} \subset \{1, 2, \ldots, q\}$ (since $k \in \{1, 2, \ldots, q\}$). Hence, (13.46.55) yields $a_{i,j} \leq 1$. In other words, $1 \geq a_{i,j}$. Qed.

Next, let us consider Case 2. In this case, we don't have $k \leq \lambda_i$. Thus, $[k \leq \lambda_i] = 0$. But (13.46.54) (applied to $j = k$) yields $a_{i,k} \geq 0$. Thus, $a_{i,k} \geq 0 = [k \leq \lambda_i]$. Hence, the inequality $a_{i,k} \geq [k \leq \lambda_i]$ is proven in Case 2.

We have now proven the inequality $a_{i,k} \geq [k \leq \lambda_i]$ in each of the two Cases 1 and 2. Thus, the inequality $a_{i,k} \geq [k \leq \lambda_i]$ always holds. This proves (13.46.58).]

Lemma 13.46.19(a) yields $\lambda_i = \sum_{j=1}^{q} a_{i,j}$. But Lemma 13.46.19(d) (applied to $k = q$) yields $\min\{\lambda_i, q\} \geq \sum_{j=1}^{q} a_{i,j}$. Hence, $\sum_{j=1}^{q} a_{i,j} \leq \min\{\lambda_i, q\}$, so that $\lambda_i = \sum_{j=1}^{q} a_{i,j} \leq \min\{\lambda_i, q\}$. If we had $\lambda_i > q$, then we would have $\min\{\lambda_i, q\} = q < \lambda_i \leq \min\{\lambda_i, q\}$, which would be absurd. Thus, we cannot have $\lambda_i > q$. We therefore must have $\lambda_i \leq q$. Hence, Lemma 13.46.18 (applied to $r = \lambda_i$) yields

$$\sum_{j=1}^{q} [j \leq \lambda_i] = \lambda_i = \sum_{j=1}^{q} a_{i,j}.$$

Thus,

$$\sum_{j=1}^{q} a_{i,j} = \sum_{j=1}^{q} [j \leq \lambda_i] \leq \sum_{j=1}^{q} [j \leq \lambda_i].$$

Also,

$$a_{i,j} \geq [j \leq \lambda_i] \qquad \text{for each } j \in \{1, 2, \ldots, q\}$$

(by (13.46.58), applied to $k = j$). Hence, Lemma 13.46.16 (applied to q, $a_{i,j}$ and $[j \leq \lambda_i]$ instead of k, a_j and b_j) shows that

$$a_{i,j} = [j \leq \lambda_i] \qquad \text{for each } j \in \{1, 2, \ldots, q\}. \tag{13.46.59}$$

Now, forget that we fixed i. We thus have proven (13.46.59) for each $i \in \{1, 2, \ldots, p\}$.

Now,

$$A = \left(\underbrace{a_{i,j}}_{\substack{=[j \leq \lambda_i] \\ (\text{by } (13.46.59))}} \right)_{1 \leq i \leq p,\ 1 \leq j \leq q} = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}.$$

This proves Lemma 13.46.19(f). □

Lemma 13.46.20. *Let $n \in \mathbb{N}$ and $q \in \mathbb{N}$. Let $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$ be such that $\ell(\mu) \leq q$. Assume that*

$$\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k \qquad \text{for each } k \in \{1, 2, \ldots, q\}.$$

Then, $\lambda \triangleright \mu$.

Proof of Lemma 13.46.20. We have assumed that

$$\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k \qquad \text{for each } k \in \{1, 2, \ldots, q\}. \tag{13.46.60}$$

Hence,

$$\lambda_1 + \lambda_2 + \cdots + \lambda_q \geq \mu_1 + \mu_2 + \cdots + \mu_q \tag{13.46.61}$$

[539].

Both λ and μ are partitions of n (since $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$). Thus, we have $\lambda \triangleright \mu$ if and only if

$$\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k \qquad \text{for all } k \in \{1, 2, \ldots, n\} \tag{13.46.62}$$

(by the definition of the dominance order).

Now, we are going to prove (13.46.62).

[*Proof of (13.46.62):* Let $k \in \{1, 2, \ldots, n\}$. We must prove that $\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k$. If $k \in \{1, 2, \ldots, q\}$, then this follows immediately from (13.46.60). Hence, for the rest of this proof, we WLOG assume that $k \notin \{1, 2, \ldots, q\}$. Combining $k \in \{1, 2, \ldots, n\} \subset \{1, 2, 3, \ldots\}$ with $k \notin \{1, 2, \ldots, q\}$, we

[539] *Proof of (13.46.61):* If $q = 0$, then the inequality (13.46.61) holds because both of its sides equal 0 (in fact, an empty sum is 0). Hence, for the rest of this proof, we WLOG assume that $q \neq 0$. Thus, q is a positive integer (since $q \in \mathbb{N}$). Thus, $q \in \{1, 2, \ldots, q\}$. Therefore, (13.46.60) (applied to $k = q$) yields $\lambda_1 + \lambda_2 + \cdots + \lambda_q \geq \mu_1 + \mu_2 + \cdots + \mu_q$. This proves (13.46.61).

obtain $k \in \{1,2,3,\ldots\} \setminus \{1,2,\ldots,q\} = \{q+1,q+2,q+3,\ldots\}$. Thus, $k \geq q+1 > q$. Hence, $q < k$. Recall also that $\ell(\mu) \leq q$, hence $q \geq \ell(\mu)$. Now,

$$\mu_1 + \mu_2 + \cdots + \mu_k = \sum_{i=1}^{k} \mu_i = \sum_{i=1}^{q} \mu_i + \sum_{i=q+1}^{k} \underbrace{\mu_i}_{\substack{=0 \\ (\text{since } i \geq q+1 > q \geq \ell(\mu))}} \qquad (\text{since } 0 \leq q < k)$$

$$= \sum_{i=1}^{q} \mu_i + \underbrace{\sum_{i=q+1}^{k} 0}_{=0} = \sum_{i=1}^{q} \mu_i = \mu_1 + \mu_2 + \cdots + \mu_q. \tag{13.46.63}$$

On the other hand,

$$\begin{aligned}
\lambda_1 + \lambda_2 + \cdots + \lambda_k &= \sum_{i=1}^{k} \lambda_i = \sum_{i=1}^{q} \lambda_i + \sum_{i=q+1}^{k} \underbrace{\lambda_i}_{\geq 0} \qquad (\text{since } 0 \leq q < k) \\
&\geq \sum_{i=1}^{q} \lambda_i + \underbrace{\sum_{i=q+1}^{k} 0}_{=0} = \sum_{i=1}^{q} \lambda_i = \lambda_1 + \lambda_2 + \cdots + \lambda_q \\
&\geq \mu_1 + \mu_2 + \cdots + \mu_q \qquad (\text{by (13.46.61)}) \\
&= \mu_1 + \mu_2 + \cdots + \mu_k \qquad (\text{by (13.46.63)}) .
\end{aligned}$$

This proves $\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k$. Thus, (13.46.62) is proven.]

Recall that we have $\lambda \triangleright \mu$ if and only if (13.46.62) holds. Thus, we have $\lambda \triangleright \mu$ (since (13.46.62) holds). This proves Lemma 13.46.20. □

Lemma 13.46.21. *Let $n \in \mathbb{N}$ and $q \in \mathbb{N}$. Let $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$ be such that $\ell(\lambda) \leq q$. Assume that*

$$\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k \qquad \text{for each } k \in \{1,2,\ldots,q\}.$$

Then, $\lambda \triangleright \mu$.

Proof of Lemma 13.46.21. We have assumed that

$$\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k \qquad \text{for each } k \in \{1,2,\ldots,q\}. \tag{13.46.64}$$

Both λ and μ are partitions of n (since $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$). Thus, we have $\lambda \triangleright \mu$ if and only if

$$\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k \qquad \text{for all } k \in \{1,2,\ldots,n\} \tag{13.46.65}$$

(by the definition of the dominance order).

Now, we are going to prove (13.46.65).

[*Proof of (13.46.65):* Let $k \in \{1,2,\ldots,n\}$. We must prove that $\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k$.

If $k \in \{1,2,\ldots,q\}$, then this follows immediately from (13.46.64). Hence, for the rest of this proof of $\lambda_1+\lambda_2+\cdots+\lambda_k \geq \mu_1+\mu_2+\cdots+\mu_k$, we WLOG assume that $k \notin \{1,2,\ldots,q\}$. Combining $k \in \{1,2,\ldots,n\} \subset \{1,2,3,\ldots\}$ with $k \notin \{1,2,\ldots,q\}$, we obtain $k \in \{1,2,3,\ldots\} \setminus \{1,2,\ldots,q\} = \{q+1,q+2,q+3,\ldots\}$. Thus, $k \geq q+1 > q \geq \ell(\lambda)$ (since $\ell(\lambda) \leq q$).

From $\mu \in \operatorname{Par}_n$, we obtain $|\mu| = n$. Hence, $n = |\mu| = \mu_1 + \mu_2 + \mu_3 + \cdots$ (by the definition of $|\mu|$).

But the definition of $|\lambda|$ yields

$$|\lambda| = \lambda_1 + \lambda_2 + \lambda_3 + \cdots = \sum_{i=1}^{\infty} \lambda_i = \sum_{i=1}^{k} \lambda_i + \sum_{i=k+1}^{\infty} \underbrace{\lambda_i}_{\substack{=0 \\ (\text{since } i \geq k+1 > k > \ell(\lambda))}} = \sum_{i=1}^{k} \lambda_i + \underbrace{\sum_{i=k+1}^{\infty} 0}_{=0}$$

$$= \sum_{i=1}^{k} \lambda_i = \lambda_1 + \lambda_2 + \cdots + \lambda_k.$$

Thus,

$$\begin{aligned}\lambda_1+\lambda_2+\cdots+\lambda_k=|\lambda|=n \qquad &(\text{since } \lambda\in\operatorname{Par}_n)\\ &=\mu_1+\mu_2+\mu_3+\cdots=\sum_{i=1}^{\infty}\mu_i=\sum_{i=1}^{k}\mu_i+\sum_{i=k+1}^{\infty}\underbrace{\mu_i}_{\geq 0}\\ &\geq\sum_{i=1}^{k}\mu_i+\underbrace{\sum_{i=k+1}^{\infty}0}_{=0}=\sum_{i=1}^{k}\mu_i=\mu_1+\mu_2+\cdots+\mu_k.\end{aligned}$$

This proves $\lambda_1+\lambda_2+\cdots+\lambda_k\geq\mu_1+\mu_2+\cdots+\mu_k$. Thus, (13.46.65) is proven.]

Recall that we have $\lambda\triangleright\mu$ if and only if (13.46.65) holds. Thus, we have $\lambda\triangleright\mu$ (since (13.46.65) holds). This proves Lemma 13.46.21. □

Lemma 13.46.22. *Let $n\in\mathbb{N}$, $p\in\mathbb{N}$ and $q\in\mathbb{N}$. Let $\lambda\in\operatorname{Par}_n$ and $\mu\in\operatorname{Par}_n$. Let $A\in\{0,1\}^{p\times q}$ be a $\{0,1\}$-matrix having row sums λ and column sums μ. Then:*

(a) *We have $\lambda^t\triangleright\mu$.*
(b) *If $\mu=\lambda^t$, then $A=([j\leq\lambda_i])_{1\leq i\leq p,\ 1\leq j\leq q}$.*

Proof of Lemma 13.46.22. The row sums of A is λ (since A has row sums λ). Thus, λ is a p-tuple (since the row sums of A is a p-tuple). Therefore, $\lambda=(\lambda_1,\lambda_2,\ldots,\lambda_p)$. Thus, $(\lambda_1,\lambda_2,\ldots,\lambda_p)$ is the row sums of A (since λ is the row sums of A).

The column sums of A is μ (since A has column sums μ). Thus, μ is a q-tuple (since the column sums of A is a q-tuple). Therefore, $\mu=(\mu_1,\mu_2,\ldots,\mu_q)$. Thus, $(\mu_1,\mu_2,\ldots,\mu_q)$ is the column sums of A (since μ is the column sums of A). From $\mu=(\mu_1,\mu_2,\ldots,\mu_q)$, we obtain $\ell(\mu)\leq q$.

We have $|\lambda^t|=|\lambda|$ (since the transpose of a partition always has the same size as the partition itself). But $|\lambda|=n$ (since $\lambda\in\operatorname{Par}_n$). Hence, $|\lambda^t|=|\lambda|=n$, so that $\lambda^t\in\operatorname{Par}_n$.

Write the $p\times q$-matrix A in the form $A=(a_{i,j})_{1\leq i\leq p,\ 1\leq j\leq q}$. Hence, Lemma 13.46.19(e) shows that we have

$$\sum_{i=1}^{p}\min\{\lambda_i,k\}\geq\sum_{j=1}^{k}\mu_j \tag{13.46.66}$$

for each $k\in\{0,1,\ldots,q\}$.

But $\lambda\in\operatorname{Par}_n\subset\operatorname{Par}$. Hence, Lemma 13.45.1 (applied to $\nu=\lambda$) shows that

$$\left(\lambda^t\right)_1+\left(\lambda^t\right)_2+\cdots+\left(\lambda^t\right)_k=\sum_{j=1}^{\infty}\min\{\lambda_j,k\} \tag{13.46.67}$$

for every $k \in \mathbb{N}$. Hence, every $k \in \{1, 2, \ldots, q\}$ satisfies

$$\begin{aligned}
\left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_k &= \sum_{j=1}^{\infty} \min\{\lambda_j, k\} \qquad \text{(by (13.46.67))} \\
&= \sum_{j=1}^{p} \min\{\lambda_j, k\} + \sum_{j=p+1}^{\infty} \underbrace{\min\{\lambda_j, k\}}_{\geq 0} \\
&\geq \sum_{j=1}^{p} \min\{\lambda_j, k\} + \underbrace{\sum_{j=p+1}^{\infty} 0}_{=0} = \sum_{j=1}^{p} \min\{\lambda_j, k\} \\
&= \sum_{i=1}^{p} \min\{\lambda_i, k\} \qquad (13.46.68) \\
&\qquad \text{(here, we have renamed the summation index } j \text{ as } i\text{)} \\
&\geq \sum_{j=1}^{k} \mu_j \qquad \text{(by (13.46.66))} \\
&= \mu_1 + \mu_2 + \cdots + \mu_k.
\end{aligned}$$

Hence, Lemma 13.46.20 (applied to λ^t instead of λ) shows that $\lambda^t \rhd \mu$. This proves Lemma 13.46.22(a).

(b) Assume that $\mu = \lambda^t$.

Let $k \in \{1, 2, \ldots, q\}$. Then, (13.46.68) shows that

$$\left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_k \geq \sum_{i=1}^{p} \min\{\lambda_i, k\}.$$

Hence,

$$\sum_{i=1}^{p} \min\{\lambda_i, k\} \leq \left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_k = \sum_{j=1}^{k} \Bigg(\underbrace{\lambda^t}_{=\mu}\Bigg)_j = \sum_{j=1}^{k} \mu_j.$$

Combining this with (13.46.66), we obtain $\sum_{i=1}^{p} \min\{\lambda_i, k\} = \sum_{j=1}^{k} \mu_j$.

Now, forget that we fixed k. We thus have proven that $\left(\sum_{i=1}^{p} \min\{\lambda_i, k\} = \sum_{j=1}^{k} \mu_j \text{ for each } k \in \{1, 2, \ldots, q\}\right)$. Hence, Lemma 13.46.19(f) shows that $A = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$. This proves Lemma 13.46.22(b). □

Lemma 13.46.23. *Let $p \in \mathbb{N}$ and $q \in \mathbb{N}$. Let λ be a partition satisfying $\ell(\lambda) \leq p$ and $\lambda_1 \leq q$.*

Let B be the $p \times q$-matrix $([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$.

Then, B is a $\{0,1\}$-matrix having row sums λ and column sums λ^t.

Proof of Lemma 13.46.23. We have $[j \leq \lambda_i] \in \{0,1\}$ for each $i \in \{1, 2, \ldots, p\}$ and $j \in \{1, 2, \ldots, q\}$ (since $[\mathcal{A}] \in \{0,1\}$ for any logical statement $\mathcal{A}$). Hence, $([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q} \in \{0,1\}^{p \times q}$.

Thus, $B = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q} \in \{0,1\}^{p \times q}$. Therefore, B is a $\{0,1\}$-matrix.

From $\ell(\lambda) \leq p$, we obtain $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p)$.

Let $\left(\widetilde{\lambda}_1, \widetilde{\lambda}_2, \ldots, \widetilde{\lambda}_p\right)$ be the row sums of B. Let $(\widetilde{\mu}_1, \widetilde{\mu}_2, \ldots, \widetilde{\mu}_q)$ be the column sums of B.

Lemma 13.46.19(a) (applied to B, $\widetilde{\lambda}_i$, $\widetilde{\mu}_j$ and $[j \leq \lambda_i]$ instead of A, λ_i, μ_j and $a_{i,j}$) shows that we have

$$\widetilde{\lambda}_i = \sum_{j=1}^{q} [j \leq \lambda_i] \qquad \text{for each } i \in \{1, 2, \ldots, p\} \tag{13.46.69}$$

(since $B = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$).

Lemma 13.46.19(b) (applied to B, $\widetilde{\lambda}_i$, $\widetilde{\mu}_j$ and $[j \leq \lambda_i]$ instead of A, λ_i, μ_j and $a_{i,j}$) shows that we have

$$\widetilde{\mu}_j = \sum_{i=1}^{p} [j \leq \lambda_i] \qquad \text{for each } j \in \{1, 2, \ldots, q\} \tag{13.46.70}$$

(since $B = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$).

We have

$$\lambda_i \leq q \tag{13.46.71}$$

for each $i \in \{1, 2, 3, \ldots\}$ [540].

Let $i \in \{1, 2, \ldots, p\}$. Then, $\lambda_i \leq q$ (by (13.46.71)). Hence, Lemma 13.46.18 (applied to $r = \lambda_i$) yields $\sum_{j=1}^{q} [j \leq \lambda_i] = \lambda_i$. Hence, (13.46.69) becomes $\widetilde{\lambda}_i = \sum_{j=1}^{q} [j \leq \lambda_i] = \lambda_i$.

Now, forget that we fixed i. We thus have shown that $\widetilde{\lambda}_i = \lambda_i$ for each $i \in \{1, 2, \ldots, p\}$. In other words, $\left(\widetilde{\lambda}_1, \widetilde{\lambda}_2, \ldots, \widetilde{\lambda}_p\right) = (\lambda_1, \lambda_2, \ldots, \lambda_p) = \lambda$ (since $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p)$). Thus, the row sums of B is λ (since the row sums of B is $\left(\widetilde{\lambda}_1, \widetilde{\lambda}_2, \ldots, \widetilde{\lambda}_p\right)$). In other words, the matrix B has row sums λ.

On the other hand, the definition (2.2.7) of the conjugate partition λ^t of λ shows that

$$\left(\lambda^t\right)_i = |\{j \in \{1, 2, 3, \ldots\} \mid \lambda_j \geq i\}| \tag{13.46.72}$$

for every positive integer i.

Now, let $k \in \{1, 2, \ldots, q\}$. Applying (13.46.72) to $i = k$, we obtain

$$\left(\lambda^t\right)_k = |\{j \in \{1, 2, 3, \ldots\} \mid \lambda_j \geq k\}| . \tag{13.46.73}$$

But (13.46.70) (applied to $j = k$) shows that

$$\begin{aligned}
\widetilde{\mu}_k &= \underbrace{\sum_{i=1}^{p}}_{=\sum_{i \in \{1,2,\ldots,p\}}} \Bigg[\underbrace{k \leq \lambda_i}_{\iff (\lambda_i \geq k)}\Bigg] = \sum_{i \in \{1,2,\ldots,p\}} [\lambda_i \geq k] \\
&= \sum_{\substack{i \in \{1,2,\ldots,p\}; \\ \lambda_i \geq k}} \underbrace{[\lambda_i \geq k]}_{\substack{=1 \\ (\text{since } \lambda_i \geq k)}} + \sum_{\substack{i \in \{1,2,\ldots,p\}; \\ \text{not } \lambda_i \geq k}} \underbrace{[\lambda_i \geq k]}_{\substack{=0 \\ (\text{since we don't have } \lambda_i \geq k)}} \\
&= \sum_{\substack{i \in \{1,2,\ldots,p\}; \\ \lambda_i \geq k}} 1 + \underbrace{\sum_{\substack{i \in \{1,2,\ldots,p\}; \\ \text{not } \lambda_i \geq k}} 0}_{=0} = \sum_{\substack{i \in \{1,2,\ldots,p\}; \\ \lambda_i \geq k}} 1 \\
&= |\{i \in \{1, 2, \ldots, p\} \mid \lambda_i \geq k\}| \cdot 1 = |\{i \in \{1, 2, \ldots, p\} \mid \lambda_i \geq k\}| \\
&= |\{j \in \{1, 2, \ldots, p\} \mid \lambda_j \geq k\}| \qquad (13.46.74)
\end{aligned}$$

(here, we have renamed the index i as j). But

$$\{j \in \{1, 2, 3, \ldots\} \mid \lambda_j \geq k\} = \{j \in \{1, 2, \ldots, p\} \mid \lambda_j \geq k\} \tag{13.46.75}$$

[540] *Proof of (13.46.71):* Let $i \in \{1, 2, 3, \ldots\}$. Thus, $i \geq 1$, so that $1 \leq i$.

The sequence λ is a partition, and thus is weakly decreasing. In other words, $\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \cdots$. Hence, $\lambda_1 \geq \lambda_i$ (since $1 \leq i$). Thus, $\lambda_i \leq \lambda_1 \leq q$. This proves (13.46.71).

[541]. Hence, (13.46.73) becomes

$$\left(\lambda^t\right)_k = \left| \underbrace{\left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq k\right\}}_{\substack{=\{j\in\{1,2,\ldots,p\} \mid \lambda_j \geq k\} \\ \text{(by (13.46.75))}}} \right| = \left|\left\{j \in \{1,2,\ldots,p\} \mid \lambda_j \geq k\right\}\right| = \widetilde{\mu}_k$$

(by (13.46.74)).

Now, forget that we fixed k. We thus have shown that $\left(\lambda^t\right)_k = \widetilde{\mu}_k$ for each $k \in \{1,2,\ldots,q\}$. In other words,

$$\left(\left(\lambda^t\right)_1, \left(\lambda^t\right)_2, \ldots, \left(\lambda^t\right)_q\right) = \left(\widetilde{\mu}_1, \widetilde{\mu}_2, \ldots, \widetilde{\mu}_q\right).$$

But $\left(\lambda^t\right)_i = 0$ for each integer $i > q$ [542]. In other words, $\left(\lambda^t\right)_{q+1} = \left(\lambda^t\right)_{q+2} = \left(\lambda^t\right)_{q+3} = \cdots = 0$. Hence, $\lambda^t = \left(\left(\lambda^t\right)_1, \left(\lambda^t\right)_2, \ldots, \left(\lambda^t\right)_q\right)$ (since we omit trailing zeroes from a partition). Thus,

$$\lambda^t = \left(\left(\lambda^t\right)_1, \left(\lambda^t\right)_2, \ldots, \left(\lambda^t\right)_q\right) = \left(\widetilde{\mu}_1, \widetilde{\mu}_2, \ldots, \widetilde{\mu}_q\right) = (\text{the column sums of } B)$$

(since $\left(\widetilde{\mu}_1, \widetilde{\mu}_2, \ldots, \widetilde{\mu}_q\right)$ is the column sums of B). In other words, the matrix B has column sums λ^t.

Hence, we know that the matrix B has row sums λ and column sums λ^t. Thus, B is a $\{0,1\}$-matrix having row sums λ and column sums λ^t (since B is a $\{0,1\}$-matrix). This proves Lemma 13.46.23. □

Lemma 13.46.24. *Let λ be a partition. Then:*

(a) *We have $\left(\lambda^t\right)_1 = \ell(\lambda)$.*
(b) *We have $\lambda_1 = \ell\left(\lambda^t\right)$.*

Proof of Lemma 13.46.24. (a) Write the partition λ in the form $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k, 0, 0, 0, \ldots)$ with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_k > 0$. Then, $\ell(\lambda) = k$ (by the definition of $\ell(\lambda)$). Thus, we have

$$\lambda_i = 0 \qquad \text{for each integer } i > \ell(\lambda) \tag{13.46.76}$$

(by the definition of $\ell(\lambda)$). Thus,

$$\left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\right\} = \{1,2,\ldots,k\} \tag{13.46.77}$$

[543].

[541] *Proof of (13.46.75):* Let $i \in \left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq k\right\}$. Thus, i is an element of $\{1,2,3,\ldots\}$ and satisfies $\lambda_i \geq k$.

We have $\lambda_i \geq k > 0$ (since $k \in \{1,2,\ldots,q\}$). Hence, $\lambda_i \neq 0$.

Assume (for the sake of contradiction) that $i > p$. Hence, $i > p \geq \ell(\lambda)$ (since $\ell(\lambda) \leq p$). But each integer $j > \ell(\lambda)$ satisfies $\lambda_j = 0$ (by the definition of $\ell(\lambda)$). Applying this to $j = i$, we obtain $\lambda_i = 0$ (since $i > \ell(\lambda)$). This contradicts $\lambda_i \neq 0$. This contradiction shows that our assumption (that $i > p$) was wrong. Hence, we must have $i \leq p$. Thus, $i \in \{1,2,\ldots,p\}$.

Now, forget that we fixed i. We thus have shown that each $i \in \left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq k\right\}$ satisfies $i \in \{1,2,\ldots,p\}$. In other words, $\left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq k\right\} \subset \{1,2,\ldots,p\}$. Hence,

$$\begin{aligned}\left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq k\right\} &= \{1,2,\ldots,p\} \cap \left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq k\right\} \\ &= \left\{j \in \underbrace{\{1,2,\ldots,p\} \cap \{1,2,3,\ldots\}}_{=\{1,2,\ldots,p\}} \mid \lambda_j \geq k\right\} = \left\{j \in \{1,2,\ldots,p\} \mid \lambda_j \geq k\right\}.\end{aligned}$$

This proves (13.46.75).

[542] *Proof.* Let $i > q$ be an integer. Then, $q < i$. But each $j \in \{1,2,3,\ldots\}$ satisfies $\lambda_j \leq q$ (by (13.46.71), applied to j instead of i). Hence, each $j \in \{1,2,3,\ldots\}$ satisfies $\lambda_j < i$ (since $\lambda_j \leq q < i$). In other words, no $j \in \{1,2,3,\ldots\}$ satisfies $\lambda_j \geq i$. In other words, $\left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq i\right\} = \varnothing$. Hence, (13.46.72) becomes $\left(\lambda^t\right)_i = \left|\underbrace{\left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq i\right\}}_{=\varnothing}\right| = |\varnothing| = 0$.

[543] *Proof of (13.46.77):* Let $i \in \left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\right\}$. Thus, i is an element of $\{1,2,3,\ldots\}$ and satisfies $\lambda_i \geq 1$. Thus, $\lambda_i \geq 1 > 0$, so that $\lambda_i \neq 0$.

If we had $i > \ell(\lambda)$, then we would have $\lambda_i = 0$ (by (13.46.76)), which would contradict $\lambda_i \neq 0$. Hence, we cannot have $i > \ell(\lambda)$. Thus, we must have $i \leq \ell(\lambda)$. Hence, $i \leq \ell(\lambda) = k$, so that $i \in \{1,2,\ldots,k\}$.

Now, forget that we fixed i. We thus have shown that $i \in \{1,2,\ldots,k\}$ for each $i \in \left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\right\}$. In other words, $\left\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\right\} \subset \{1,2,\ldots,k\}$.

The definition (2.2.7) of the conjugate partition λ^t of λ shows that $(\lambda^t)_i = |\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq i\}|$ for each positive integer i. Applying this to $i = 1$, we obtain

$$\left(\lambda^t\right)_1 = \left| \underbrace{\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\}}_{\substack{=\{1,2,\ldots,k\} \\ \text{(by (13.46.77))}}} \right| = |\{1,2,\ldots,k\}| = k = \ell(\lambda).$$

This proves Lemma 13.46.24(a).

(b) It is known that $(\lambda^t)^t = \lambda$. But Lemma 13.46.24(a) (applied to λ^t instead of λ) yields $\left((\lambda^t)^t\right)_1 = \ell(\lambda^t)$. In light of $(\lambda^t)^t = \lambda$, this rewrites as $\lambda_1 = \ell(\lambda^t)$. This proves Lemma 13.46.24(b). □

Now, let us resume the solution of Exercise 2.2.13.

(h) Let $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$ be two partitions that don't satisfy $\lambda^t \rhd \mu$. We must prove that $a_{\lambda,\mu} = 0$.

Indeed, there exists no $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\mu)$ having row sums λ and column sums μ [544]. Thus, the number of all $\{0,1\}$-matrices of size $\ell(\lambda) \times \ell(\mu)$ having row sums λ and column sums μ equals 0. In other words, $a_{\lambda,\mu}$ equals 0 (since $a_{\lambda,\mu}$ is the number of all $\{0,1\}$-matrices of size $\ell(\lambda) \times \ell(\mu)$ having row sums λ and column sums μ). In other words, $a_{\lambda,\mu} = 0$. This solves Exercise 2.2.13(h).

(i) Let $\lambda \in \operatorname{Par}_n$. We shall prove that $a_{\lambda,\lambda^t} = 1$.

Let $p = \ell(\lambda)$ and $q = \lambda_1$. Then, $\ell(\lambda) = p \leq p$ and $\lambda_1 = q \leq q$. Also, $q = \lambda_1 = \ell(\lambda^t)$ (by Lemma 13.46.24(b)).

Define the $p \times q$-matrix B as in Lemma 13.46.23. Then, Lemma 13.46.23 shows that B is a $\{0,1\}$-matrix having row sums λ and column sums λ^t. Furthermore, B is a $\{0,1\}$-matrix of size $p \times q$. In other words, B is a $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\lambda^t)$ (since $p = \ell(\lambda)$ and $q = \ell(\lambda^t)$). Hence, there exists **at least one** $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\lambda^t)$ having row sums λ and column sums λ^t (namely, B).

On the other hand, using Lemma 13.46.22(b), it is easy to see that every $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\lambda^t)$ having row sums λ and column sums λ^t must be equal to B [545]. Hence, there exists **at most one** $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\lambda^t)$ having row sums λ and column sums λ^t.

We know that a_{λ,λ^t} is the number of all $\{0,1\}$-matrices of size $\ell(\lambda) \times \ell(\lambda^t)$ having row sums λ and column sums λ^t (by the definition of a_{λ,λ^t}). Since there exists **exactly one** such matrix (because we have shown that there exists **at least one** such matrix, and we have also shown that there exists **at most one** such matrix), we thus conclude that $a_{\lambda,\lambda^t} = 1$.

Now, forget that we fixed λ. We thus have shown that

$$a_{\lambda,\lambda^t} = 1 \qquad \text{for every } \lambda \in \operatorname{Par}_n. \tag{13.46.78}$$

Now, let $\lambda \in \operatorname{Par}_n$. We shall show that $a_{\lambda^t,\lambda} = 1$.

It is known that $(\lambda^t)^t = \lambda$. But $|\lambda^t| = |\lambda|$ (since the transpose of a partition always has the same size as the partition itself). But $|\lambda| = n$ (since $\lambda \in \operatorname{Par}_n$). Hence, $|\lambda^t| = |\lambda| = n$, so that $\lambda^t \in \operatorname{Par}_n$. Thus,

On the other hand, let $h \in \{1,2,\ldots,k\}$. Then, $\lambda_h > 0$ (since $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_k > 0$). Hence, $\lambda_h \geq 1$ (since λ_h is an integer). Hence, h is an element of $\{1,2,3,\ldots\}$ and satisfies $\lambda_h \geq 1$. In other words, $h \in \{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\}$.

Now, forget that we fixed h. We thus have shown that $h \in \{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\}$ for each $h \in \{1,2,\ldots,k\}$. In other words, $\{1,2,\ldots,k\} \subset \{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\}$. Combining this with $\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\} \subset \{1,2,\ldots,k\}$, we obtain $\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq 1\} = \{1,2,\ldots,k\}$. This proves (13.46.77).

[544] *Proof.* Let A be a $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\mu)$ having row sums λ and column sums μ. We shall derive a contradiction.

We have $A \in \{0,1\}^{\ell(\lambda) \times \ell(\mu)}$ (since A is a $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\mu)$). Thus, Lemma 13.46.22(a) shows that $\lambda^t \rhd \mu$. This contradicts the fact that we don't have $\lambda^t \rhd \mu$.

Now, forget that we fixed A. We thus have found a contradiction for each $\{0,1\}$-matrix A of size $\ell(\lambda) \times \ell(\mu)$ having row sums λ and column sums μ. Thus, there exists no $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\mu)$ having row sums λ and column sums μ. Qed.

[545] *Proof.* Let A be a $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\lambda^t)$ having row sums λ and column sums λ^t. We must prove that $A = B$.

We know that A is a $\{0,1\}$-matrix of size $\ell(\lambda) \times \ell(\lambda^t)$. In other words, A is a $\{0,1\}$-matrix of size $p \times q$ (since $\ell(\lambda) = p$ and $\ell(\lambda^t) = q$). In other words, $A \in \{0,1\}^{p \times q}$.

We have $|\lambda^t| = |\lambda|$ (since the transpose of a partition always has the same size as the partition itself). But $|\lambda| = n$ (since $\lambda \in \operatorname{Par}_n$). Hence, $|\lambda^t| = |\lambda| = n$, so that $\lambda^t \in \operatorname{Par}_n$. Hence, Lemma 13.46.22(b) (applied to $\mu = \lambda^t$) shows that $A = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$. But the definition of B yields $B = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$. Comparing this with $A = ([j \leq \lambda_i])_{1 \leq i \leq p,\ 1 \leq j \leq q}$, we obtain $A = B$. This proves $A = B$, qed.

(13.46.78) (applied to λ^t instead of λ) yields $a_{\lambda^t,(\lambda^t)^t} = 1$. In light of $(\lambda^t)^t = \lambda$, this rewrites as $a_{\lambda^t,\lambda} = 1$. This solves Exercise 2.2.13(i).

Before we solve Exercise 2.2.13(j), let us introduce some terminology and prove some lemmas.

Definition 13.46.25. Let $m \in \mathbb{N}$. Then, $[m]$ shall denote the subset $\{1, 2, \ldots, m\}$ of $\{1, 2, 3, \ldots\}$. Notice that $|[m]| = m$ for each $m \in \mathbb{N}$.

Definition 13.46.26. Let $p \in \mathbb{N}$ and $q \in \mathbb{N}$. Let $\varphi : [p] \to [q]$ be any map. Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p) \in \mathbb{N}^p$ be a p-tuple. Then, we define a q-tuple $\varphi_* \alpha \in \mathbb{N}^q$ by

$$\varphi_* \alpha = \left(\sum_{i \in \varphi^{-1}\{1\}} \alpha_i, \sum_{i \in \varphi^{-1}\{2\}} \alpha_i, \ldots, \sum_{i \in \varphi^{-1}\{q\}} \alpha_i \right).$$

(Recall that if U is any subset of $[q]$, then $\varphi^{-1}U$ denotes the subset $\{i \in [p] \mid \varphi(i) \in U\}$ of $[p]$.)

Example 13.46.27. Let $p = 5$ and $q = 4$, and let $\varphi : [p] \to [q]$ be the map that sends $1, 2, 3, 4, 5$ to $1, 4, 4, 2, 2$, respectively. Let $\alpha = (\alpha_1, \alpha_2, \alpha_3, \alpha_4, \alpha_5) \in \mathbb{N}^5$ be a 5-tuple. Then, the 4-tuple $\varphi_* \alpha \in \mathbb{N}^4$ is

$$\varphi_* \alpha = \left(\sum_{i \in \varphi^{-1}\{1\}} \alpha_i, \sum_{i \in \varphi^{-1}\{2\}} \alpha_i, \sum_{i \in \varphi^{-1}\{3\}} \alpha_i, \sum_{i \in \varphi^{-1}\{4\}} \alpha_i \right) = (\alpha_1, \alpha_4 + \alpha_5, 0, \alpha_2 + \alpha_3)$$

(since $\varphi^{-1}\{1\} = \{1\}$, $\varphi^{-1}\{2\} = \{4, 5\}$, $\varphi^{-1}\{3\} = \varnothing$ and $\varphi^{-1}\{4\} = \{2, 3\}$).

Proposition 13.46.28. *Let p, q and r be three elements of $\mathbb{N}$. Let $\varphi : [p] \to [q]$ and $\psi : [q] \to [r]$ be any maps. Let $\alpha \in \mathbb{N}^p$. Then, $(\psi \circ \varphi)_* \alpha = \psi_* (\varphi_* \alpha)$.*

Proof of Proposition 13.46.28. Write the p-tuple $\alpha \in \mathbb{N}^p$ in the form $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p)$ for some elements $\alpha_1, \alpha_2, \ldots, \alpha_p$ of $\mathbb{N}$. Thus,

$$(\psi \circ \varphi)_* \alpha = \left(\sum_{i \in (\psi \circ \varphi)^{-1}\{1\}} \alpha_i, \sum_{i \in (\psi \circ \varphi)^{-1}\{2\}} \alpha_i, \ldots, \sum_{i \in (\psi \circ \varphi)^{-1}\{r\}} \alpha_i \right) \tag{13.46.79}$$

(by the definition of $(\psi \circ \varphi)_* \alpha$).

Write the q-tuple $\varphi_* \alpha \in \mathbb{N}^q$ in the form $\varphi_* \alpha = (\beta_1, \beta_2, \ldots, \beta_q)$ for some elements $\beta_1, \beta_2, \ldots, \beta_q$ of $\mathbb{N}$. Then,

$$(\beta_1, \beta_2, \ldots, \beta_q) = \varphi_* \alpha = \left(\sum_{i \in \varphi^{-1}\{1\}} \alpha_i, \sum_{i \in \varphi^{-1}\{2\}} \alpha_i, \ldots, \sum_{i \in \varphi^{-1}\{q\}} \alpha_i \right)$$

(by the definition of $\varphi_* \alpha$, because $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p)$). Thus,

$$\beta_j = \sum_{i \in \varphi^{-1}\{j\}} \alpha_i \qquad \text{for each } j \in [q]. \tag{13.46.80}$$

Write the r-tuple $\psi_* (\varphi_* \alpha) \in \mathbb{N}^r$ in the form $\psi_* (\varphi_* \alpha) = (\gamma_1, \gamma_2, \ldots, \gamma_r)$ for some elements $\gamma_1, \gamma_2, \ldots, \gamma_r$ of $\mathbb{N}$. Then,

$$(\gamma_1, \gamma_2, \ldots, \gamma_r) = \psi_* (\varphi_* \alpha) = \left(\sum_{i \in \psi^{-1}\{1\}} \beta_i, \sum_{i \in \psi^{-1}\{2\}} \beta_i, \ldots, \sum_{i \in \psi^{-1}\{r\}} \beta_i \right)$$

(by the definition of $\psi_* (\varphi_* \alpha)$, because $\varphi_* \alpha = (\beta_1, \beta_2, \ldots, \beta_q)$). Thus, for each $m \in [r]$, we have

$$\begin{aligned}
\gamma_m &= \underbrace{\sum_{i \in \psi^{-1}\{m\}}}_{= \sum_{\substack{i \in [q];\\ \psi(i)=m}}} \beta_i = \sum_{\substack{i \in [q];\\ \psi(i)=m}} \beta_i = \sum_{\substack{j \in [q];\\ \psi(j)=m}} \underbrace{\beta_j}_{\substack{= \sum_{i \in \varphi^{-1}\{j\}} \alpha_i \\ \text{(by (13.46.80))}}} \qquad \left(\begin{array}{c} \text{here, we have renamed the} \\ \text{summation index } i \text{ as } j \end{array} \right) \\
&= \sum_{\substack{j \in [q];\\ \psi(j)=m}} \underbrace{\sum_{i \in \varphi^{-1}\{j\}}}_{= \sum_{\substack{i \in [p];\\ \varphi(i)=j}}} \alpha_i = \underbrace{\sum_{\substack{j \in [q];\\ \psi(j)=m}} \sum_{\substack{i \in [p];\\ \varphi(i)=j}}}_{= \sum_{j \in [q]} \sum_{\substack{i \in [p];\\ \psi(j)=m;\\ \varphi(i)=j}}} \alpha_i \\
&= \sum_{j \in [q]} \underbrace{\sum_{\substack{i \in [p];\\ \psi(j)=m;\\ \varphi(i)=j}}}_{\substack{= \sum_{\substack{i \in [p];\\ \varphi(i)=j;\\ \psi(j)=m}} = \sum_{\substack{i \in [p];\\ \varphi(i)=j;\\ \psi(\varphi(i))=m}} \\ \text{(because for any } i \in [p] \text{ satisfying } \varphi(i)=j, \\ \text{the condition } (\psi(j)=m) \text{ is equivalent to } (\psi(\varphi(i))=m) \\ \text{(since } j=\varphi(i)))}} \alpha_i = \underbrace{\sum_{j \in [q]} \sum_{\substack{i \in [p];\\ \varphi(i)=j;\\ \psi(\varphi(i))=m}}}_{\substack{= \sum_{i \in [p]} \sum_{\substack{j \in [q];\\ \varphi(i)=j;\\ \psi(\varphi(i))=m}} \\ = \sum_{\substack{i \in [p];\\ \psi(\varphi(i))=m}} \sum_{\substack{j \in [q];\\ \varphi(i)=j}}}} \alpha_i \\
&= \underbrace{\sum_{\substack{i \in [p];\\ \psi(\varphi(i))=m}}}_{= \sum_{\substack{i \in [p];\\ (\psi \circ \varphi)(i)=m}} = \sum_{i \in (\psi \circ \varphi)^{-1}\{m\}}} \underbrace{\sum_{\substack{j \in [q];\\ \varphi(i)=j}} \alpha_i}_{\substack{= \alpha_i \\ \text{(since there is a} \\ \text{unique } j \in [q] \text{ satisfying } \varphi(i)=j)}} = \sum_{i \in (\psi \circ \varphi)^{-1}\{m\}} \alpha_i .
\end{aligned}$$

In other words, we have

$$(\gamma_1, \gamma_2, \ldots, \gamma_r) = \left(\sum_{i \in (\psi \circ \varphi)^{-1}\{1\}} \alpha_i, \sum_{i \in (\psi \circ \varphi)^{-1}\{2\}} \alpha_i, \ldots, \sum_{i \in (\psi \circ \varphi)^{-1}\{r\}} \alpha_i \right).$$

Comparing this with (13.46.79), we obtain

$$(\psi \circ \varphi)_* \alpha = (\gamma_1, \gamma_2, \ldots, \gamma_r) = \psi_* (\varphi_* \alpha)$$

(since $\psi_* (\varphi_* \alpha) = (\gamma_1, \gamma_2, \ldots, \gamma_r)$). This proves Proposition 13.46.28. □

Proposition 13.46.29. *Let $p \in \mathbb{N}$. Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p) \in \mathbb{N}^p$. Let $\sigma \in \mathfrak{S}_p$. Then:*

(a) *The p-tuple $\sigma_* \alpha$ is well-defined and satisfies $\sigma_* \alpha = \left(\alpha_{\sigma^{-1}(1)}, \alpha_{\sigma^{-1}(2)}, \ldots, \alpha_{\sigma^{-1}(p)} \right)$.*

(b) *We have $\sigma_* \alpha = \alpha$ if and only if $\left(\alpha_{\sigma(i)} = \alpha_i \text{ for all } i \in [p] \right)$.*

Proof of Proposition 13.46.29. We have $\sigma \in \mathfrak{S}_p$. In other words, σ is a permutation of $[p]$ (since $\mathfrak{S}_p$ is the set of all permutations of $[p]$ (because $[p] = \{1, 2, \ldots, p\}$)). In other words, σ is a bijection $[p] \to [p]$. Thus, the p-tuple $\sigma_* \alpha$ is well-defined (since $\alpha \in \mathbb{N}^p$). The definition of $\sigma_* \alpha$ yields

$$\sigma_* \alpha = \left(\sum_{i \in \sigma^{-1}\{1\}} \alpha_i, \sum_{i \in \sigma^{-1}\{2\}} \alpha_i, \ldots, \sum_{i \in \sigma^{-1}\{p\}} \alpha_i \right). \tag{13.46.81}$$

But each $j \in [p]$ satisfies

$$\begin{aligned}
\sum_{i \in \sigma^{-1}\{j\}} \alpha_i &= \sum_{i \in \{\sigma^{-1}(j)\}} \alpha_i \qquad \left(\text{since } \sigma^{-1}\{j\} = \left\{ \sigma^{-1}(j) \right\} \text{ (because } \sigma \text{ is a bijection)} \right) \\
&= \alpha_{\sigma^{-1}(j)}.
\end{aligned}$$

In other words,

$$\left(\sum_{i\in\sigma^{-1}\{1\}}\alpha_i,\sum_{i\in\sigma^{-1}\{2\}}\alpha_i,\ldots,\sum_{i\in\sigma^{-1}\{p\}}\alpha_i\right)=\left(\alpha_{\sigma^{-1}(1)},\alpha_{\sigma^{-1}(2)},\ldots,\alpha_{\sigma^{-1}(p)}\right).$$

Hence, (13.46.81) becomes

$$\sigma_*\alpha=\left(\sum_{i\in\sigma^{-1}\{1\}}\alpha_i,\sum_{i\in\sigma^{-1}\{2\}}\alpha_i,\ldots,\sum_{i\in\sigma^{-1}\{p\}}\alpha_i\right)=\left(\alpha_{\sigma^{-1}(1)},\alpha_{\sigma^{-1}(2)},\ldots,\alpha_{\sigma^{-1}(p)}\right).$$

This completes the proof of Proposition 13.46.29(a).

(b) We have the following chain of logical equivalences:

$$\begin{aligned}
&\left(\underbrace{\sigma_*\alpha}_{=\left(\alpha_{\sigma^{-1}(1)},\alpha_{\sigma^{-1}(2)},\ldots,\alpha_{\sigma^{-1}(p)}\right)}=\underbrace{\alpha}_{=(\alpha_1,\alpha_2,\ldots,\alpha_p)}\right)\\
\Longleftrightarrow\ &\left(\left(\alpha_{\sigma^{-1}(1)},\alpha_{\sigma^{-1}(2)},\ldots,\alpha_{\sigma^{-1}(p)}\right)=(\alpha_1,\alpha_2,\ldots,\alpha_p)\right)\\
\Longleftrightarrow\ &\left(\alpha_{\sigma^{-1}(j)}=\alpha_j\text{ for all }j\in[p]\right)\\
\Longleftrightarrow\ &\left(\underbrace{\alpha_{\sigma^{-1}(\sigma(i))}}_{\substack{=\alpha_i\\(\text{since }\sigma^{-1}(\sigma(i))=i)}}=\alpha_{\sigma(i)}\text{ for all }i\in[p]\right)\\
&\qquad(\text{here, we have substituted }\sigma(i)\text{ for }j\text{, since the map }\sigma:[p]\to[p]\text{ is a bijection})\\
\Longleftrightarrow\ &\left(\alpha_i=\alpha_{\sigma(i)}\text{ for all }i\in[p]\right)\\
\Longleftrightarrow\ &\left(\alpha_{\sigma(i)}=\alpha_i\text{ for all }i\in[p]\right).
\end{aligned}$$

This proves Proposition 13.46.29(b). □

Proposition 13.46.30. *Let $p\in\mathbb{N}$. Let $\alpha\in\mathbb{N}^p$. Then, $\left(\mathrm{id}_{[p]}\right)_*\alpha=\alpha$.*

Proof of Proposition 13.46.30. Clearly, $\mathrm{id}_{[p]}\in\mathfrak{S}_p$. Write the p-tuple $\alpha\in\mathbb{N}^p$ in the form $\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_p)$ for some elements $\alpha_1,\alpha_2,\ldots,\alpha_p$ of $\mathbb{N}$. Thus, Proposition 13.46.29(a) (applied to $\sigma=\mathrm{id}_{[p]}$) shows that the p-tuple $\left(\mathrm{id}_{[p]}\right)_*\alpha$ is well-defined and satisfies $\left(\mathrm{id}_{[p]}\right)_*\alpha=\left(\alpha_{\left(\mathrm{id}_{[p]}\right)^{-1}(1)},\alpha_{\left(\mathrm{id}_{[p]}\right)^{-1}(2)},\ldots,\alpha_{\left(\mathrm{id}_{[p]}\right)^{-1}(p)}\right)$. Hence,

$$\begin{aligned}
\left(\mathrm{id}_{[p]}\right)_*\alpha&=\left(\alpha_{\left(\mathrm{id}_{[p]}\right)^{-1}(1)},\alpha_{\left(\mathrm{id}_{[p]}\right)^{-1}(2)},\ldots,\alpha_{\left(\mathrm{id}_{[p]}\right)^{-1}(p)}\right)\\
&=(\alpha_1,\alpha_2,\ldots,\alpha_p)\qquad\left(\text{since }\left(\mathrm{id}_{[p]}\right)^{-1}(i)=i\text{ for all }i\in[p]\right)\\
&=\alpha.
\end{aligned}$$

This proves Proposition 13.46.30. □

Lemma 13.46.31. *Let $p\in\mathbb{N}$ and $q\in\mathbb{N}$. Let $\varphi:[p]\to[q]$ be any map. Let $\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_p)\in\mathbb{N}^p$ be a p-tuple. Let $\beta=(\beta_1,\beta_2,\ldots,\beta_q)\in\mathbb{N}^q$ be a q-tuple such that ($\beta_i>0$ for each $i\in[q]$) and $\beta=\varphi_*\alpha$. Then, the map φ is surjective.*

Proof of Lemma 13.46.31. We have

$$(\beta_1,\beta_2,\ldots,\beta_q)=\beta=\varphi_*\alpha=\left(\sum_{i\in\varphi^{-1}\{1\}}\alpha_i,\sum_{i\in\varphi^{-1}\{2\}}\alpha_i,\ldots,\sum_{i\in\varphi^{-1}\{q\}}\alpha_i\right)$$

(by the definition of $\varphi_*\alpha$, since $\alpha=(\alpha_1,\alpha_2,\ldots,\alpha_p)$). In other words,

$$\beta_j=\sum_{i\in\varphi^{-1}\{j\}}\alpha_i\qquad\text{for each }j\in[q].\tag{13.46.82}$$

Let $j \in [q]$. Assume (for the sake of contradiction) that $\varphi^{-1}\{j\} = \varnothing$. Thus, $\sum_{i \in \varphi^{-1}\{j\}} \alpha_i = \sum_{i \in \varnothing} \alpha_i = (\text{empty sum}) = 0$. Thus, (13.46.82) becomes $\beta_j = \sum_{i \in \varphi^{-1}\{j\}} \alpha_i = 0$. But recall that ($\beta_i > 0$ for each $i \in [q]$). Applying this to $i = j$, we obtain $\beta_j > 0$. This contradicts $\beta_j = 0$.

This contradiction shows that our assumption (that $\varphi^{-1}\{j\} = \varnothing$) was wrong. Hence, we have $\varphi^{-1}\{j\} \neq \varnothing$. Hence, there exists some $k \in \varphi^{-1}\{j\}$. Consider this k.

From $k \in \varphi^{-1}\{j\}$, we obtain $\varphi(k) \in \{j\}$, so that $\varphi(k) = j$. Hence, $j = \varphi\left(\underbrace{k}_{\in \varphi^{-1}\{j\} \subset [p]}\right) \in \varphi([p])$.

Now, forget that we fixed j. We thus have shown that $j \in \varphi([p])$ for each $j \in [q]$. In other words, $[q] \subset \varphi([p])$. In other words, the map φ is surjective. This proves Lemma 13.46.31. □

Lemma 13.46.32. *Let $(\beta_1, \beta_2, \beta_3, \ldots) \in \mathbb{N}^\infty$ be such that $\beta_1 \geq \beta_2 \geq \beta_3 \geq \cdots$. Let $k \in \mathbb{N}$. Let R be a finite subset of $\{1, 2, 3, \ldots\}$ such that $|R| \leq k$. Then,*

$$\sum_{r \in R} \beta_r \leq \beta_1 + \beta_2 + \cdots + \beta_k.$$

Proof of Lemma 13.46.32. We have $\beta_1 \geq \beta_2 \geq \beta_3 \geq \cdots$. In other words, if u and v are two elements of $\{1, 2, 3, \ldots\}$ satisfying $u \leq v$, then

$$\beta_u \geq \beta_v. \tag{13.46.83}$$

Let $(r_1, r_2, \ldots, r_p)$ be a list of all elements of R in increasing order (with no repetitions). Thus, $\sum_{r \in R} \beta_r = \beta_{r_1} + \beta_{r_2} + \cdots + \beta_{r_p}$ and $R = \{r_1, r_2, \ldots, r_p\}$ and $|R| = p$ and $r_1 < r_2 < \cdots < r_p$.

Hence, $p = |R| \leq k$, so that $0 \leq p \leq k$. Furthermore, $\{r_1, r_2, \ldots, r_p\} = R \subset \{1, 2, 3, \ldots\}$.

But each $j \in \{1, 2, \ldots, p-1\}$ satisfies

$$r_{j+1} - r_j \geq 1 \tag{13.46.84}$$

[546]. Thus, each $i \in \{1, 2, \ldots, p\}$ satisfies

$$r_i \geq i \tag{13.46.85}$$

[547]. Hence, each $i \in \{1, 2, \ldots, p\}$ satisfies

$$\beta_{r_i} \leq \beta_i \tag{13.46.86}$$

[548].

Now,

$$\sum_{r \in R} \beta_r = \beta_{r_1} + \beta_{r_2} + \cdots + \beta_{r_p} = \sum_{i=1}^{p} \underbrace{\beta_{r_i}}_{\substack{\leq \beta_i \\ (\text{by } (13.46.86))}} \leq \sum_{i=1}^{p} \beta_i. \tag{13.46.87}$$

[546] *Proof of (13.46.84):* Let $j \in \{1, 2, \ldots, p-1\}$. Then, $r_j < r_{j+1}$ (since $r_1 < r_2 < \cdots < r_p$). Hence, $r_j \leq r_{j+1} - 1$ (since r_j and r_{j+1} are integers). In other words, $r_{j+1} - r_j \geq 1$. This proves (13.46.84).

[547] *Proof of (13.46.85):* Let $i \in \{1, 2, \ldots, p\}$. Then, $\sum_{j=1}^{i-1} (r_{j+1} - r_j) = r_i - r_1$ (by the telescope principle). Hence,

$$r_i - r_1 = \sum_{j=1}^{i-1} \underbrace{(r_{j+1} - r_j)}_{\substack{\geq 1 \\ (\text{by } (13.46.84))}} \geq \sum_{j=1}^{i-1} 1 = i - 1.$$

Hence, $r_i \geq (i-1) + r_1$. But $r_1 \geq 1$ (since $r_1 \in \{r_1, r_2, \ldots, r_p\} \subset \{1, 2, 3, \ldots\}$). Thus, $r_i \geq (i-1) + \underbrace{r_1}_{\geq 1} \geq (i-1) + 1 = i$. This proves (13.46.85).

[548] *Proof of (13.46.86):* Let $i \in \{1, 2, \ldots, p\}$. From (13.46.85), we obtain $r_i \geq i$. Thus, $i \leq r_i$. Hence, (13.46.83) (applied to r_i and i instead of u and v) shows that $\beta_i \geq \beta_{r_i}$. In other words, $\beta_{r_i} \leq \beta_i$. This proves (13.46.86).

But

$$\beta_1 + \beta_2 + \cdots + \beta_k = \sum_{i=1}^{k} \beta_i = \sum_{i=1}^{p} \beta_i + \sum_{i=p+1}^{k} \underbrace{\beta_i}_{\substack{\geq 0 \\ (\text{since } \beta_i \in \mathbb{N})}}$$

(here, we have split the sum into two at $i = p$ (since $0 \leq p \leq k$))

$$\geq \sum_{i=1}^{p} \beta_i + \underbrace{\sum_{i=p+1}^{k} 0}_{=0} = \sum_{i=1}^{p} \beta_i \geq \sum_{r \in R} \beta_r \qquad (\text{by } (13.46.87)).$$

In other words, $\sum_{r \in R} \beta_r \leq \beta_1 + \beta_2 + \cdots + \beta_k$. This proves Lemma 13.46.32. □

We now introduce some notations:

Definition 13.46.33. Let $p \in \mathbb{N}$ and $q \in \mathbb{N}$. Let $\alpha \in \mathbb{N}^p$ and $\beta \in \mathbb{N}^q$. Then, we define a set $\mathfrak{B}_{\alpha,\beta,p,q}$ by

$$\mathfrak{B}_{\alpha,\beta,p,q} = \{\varphi : [p] \to [q] \mid \beta = \varphi_* \alpha\}.$$

Note that this set $\mathfrak{B}_{\alpha,\beta,p,q}$ is a subset of $\{\varphi : [p] \to [q]\} = [q]^{[p]}$, and therefore is a finite set (since $[q]^{[p]}$ is a finite set).

Example 13.46.34. Let $p = 3$, $q = 4$, $\alpha = (2, 1, 2)$ and $\beta = (3, 0, 2, 0)$. Then, $\mathfrak{B}_{\alpha,\beta,p,q} = \{\varphi_1, \varphi_2\}$, where φ_1 and φ_2 are the two maps $[3] \to [4]$ defined by

$$\begin{aligned} &\varphi_1(1) = 1, \qquad &&\varphi_1(2) = 1, \qquad &&\varphi_1(3) = 3; \\ &\varphi_2(1) = 3, &&\varphi_2(2) = 1, &&\varphi_2(3) = 1. \end{aligned}$$

Notice that $\mathfrak{B}_{\alpha,\beta,p,q}$ depends nontrivially on p and q. Indeed, recall that we are identifying any k-tuple $(a_1, a_2, \ldots, a_k) \in \mathbb{N}^k$ with the weak composition $(a_1, a_2, \ldots, a_k, 0, 0, 0, \ldots)$; therefore, any two tuples of nonnegative integers that differ only in trailing zeroes are equated with each other (for example, $(2, 3)$ is equated with $(2, 3, 0)$), because they are being identified with one and the same weak composition. Thus, for example, the 3-tuple $\alpha = (2, 1, 2)$ is equated with the 4-tuple $\alpha' = (2, 1, 2, 0)$. But the set $\mathfrak{B}_{\alpha,\beta,p,q} = \mathfrak{B}_{\alpha,\beta,3,4}$ cannot be equated with $\mathfrak{B}_{\alpha',\beta,4,4}$; indeed, the set $\mathfrak{B}_{\alpha',\beta,4,4}$ has more than two elements (due to the extra choice in picking the image of 4 under the map $\varphi \in \mathfrak{B}_{\alpha',\beta,4,4}$), and so we have $|\mathfrak{B}_{\alpha,\beta,3,4}| \neq |\mathfrak{B}_{\alpha',\beta,4,4}|$.

Remark 13.46.35. We recall that every k-tuple $(a_1, a_2, \ldots, a_k) \in \mathbb{N}^k$ is identified with the weak composition $(a_1, a_2, \ldots, a_k, 0, 0, 0, \ldots)$. Thus, conversely, any weak composition $\alpha = (\alpha_1, \alpha_2, \alpha_3, \ldots)$ is identified with any k-tuple that is obtained from it by removing trailing zeroes. For example, the weak composition $(2, 0, 3, 0, 0, 0, \ldots)$ is identified with the 3-tuple $(2, 0, 3)$, with the 4-tuple $(2, 0, 3, 0)$, and so on.

These identifications have an important consequence: If λ and μ are two weak compositions, then there exist nonnegative integers p and q for which λ can be identified with a p-tuple (namely, with $(\lambda_1, \lambda_2, \ldots, \lambda_p)$) and μ can be identified with a q-tuple (namely, with $(\mu_1, \mu_2, \ldots, \mu_q)$). Any two such integers p and q give rise to a well-defined set $\mathfrak{B}_{\lambda,\mu,p,q}$, defined by regarding λ as a p-tuple and regarding μ as a q-tuple.

Definition 13.46.36. Let $\lambda \in \operatorname{Par}$ and $\mu \in \mathbb{N}^\infty$. Let $\ell = \ell(\lambda)$. Then, we define a set $\mathfrak{B}'_{\lambda,\mu}$ by

$$\mathfrak{B}'_{\lambda,\mu} = \left\{ \varphi : [\ell] \to \{1, 2, 3, \ldots\} \mid \mu_j = \sum_{\substack{i \in [\ell]; \\ \varphi(i) = j}} \lambda_i \text{ for all } j \in \{1, 2, 3, \ldots\} \right\}.$$

Definition 13.46.37. Let X, Y and Z be three sets such that $X \subset Y$. Let $g : Z \to X$ be any map. Then, we define a map $g\mid^Y : Z \to Y$ by

$$\left(\left(g \mid^Y \right)(z) = g(z) \qquad \text{for each } z \in Z \right).$$

(This is well-defined, since each $z \in Z$ satisfies $g(z) \in X \subset Y$.)

The map $g\mid^Y$ is identical to the map g except for the fact that its target is Y rather than X.

If X, Y and Z are three sets such that $X \subset Y$, then the maps of the form $g \mid^{Y}$ (with g being a map $Z \to X$) are exactly those maps $Z \to Y$ whose image is contained in X. More precisely, the following lemma holds:

Lemma 13.46.38. *Let X, Y and Z be three sets such that $X \subset Y$. Then, the map*

$$X^Z \to \left\{ f \in Y^Z \mid f(Z) \subset X \right\}, \\ g \mapsto g \mid^{Y}$$

is a bijection.

Proof of Lemma 13.46.38. Lemma 13.46.38 is a fundamental fact about sets. We thus omit its proof. □

Proposition 13.46.39. *Let $\lambda \in \operatorname{Par}$ and $\mu \in \operatorname{WC}$. Let $p = \ell(\lambda)$. From $p = \ell(\lambda)$, we obtain $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p)$; thus, λ is a p-tuple in $\mathbb{N}^p$. Let $q \in \mathbb{N}$ be such that $\mu = (\mu_1, \mu_2, \ldots, \mu_q)$ (that is, $\mu_i = 0$ for all integers $i > q$). Thus, μ is a q-tuple in $\mathbb{N}^q$. Hence, the set $\mathfrak{B}_{\lambda,\mu,p,q}$ is well-defined (since $\lambda \in \mathbb{N}^p$ and $\mu \in \mathbb{N}^q$).*

Now, $\mathfrak{B}'_{\lambda,\mu} \cong \mathfrak{B}_{\lambda,\mu,p,q}$ as sets.

Proof of Proposition 13.46.39. We have $\mu = (\mu_1, \mu_2, \ldots, \mu_q)$. In other words,

$$\mu_j = 0 \qquad \text{for each } j \in \{q+1, q+2, q+3, \ldots\}. \tag{13.46.88}$$

We have $p = \ell(\lambda)$. Hence, $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_p > 0$ (by the definition of $\ell(\lambda)$). Therefore,

$$\lambda_k > 0 \qquad \text{for each } k \in [p]. \tag{13.46.89}$$

The definition of $\mathfrak{B}_{\lambda,\mu,p,q}$ shows that

$$\mathfrak{B}_{\lambda,\mu,p,q} = \{\varphi : [p] \to [q] \mid \mu = \varphi_* \lambda\}$$

(where, of course, λ and μ are regarded as the tuples $(\lambda_1, \lambda_2, \ldots, \lambda_p) \in \mathbb{N}^p$ and $(\mu_1, \mu_2, \ldots, \mu_q) \in \mathbb{N}^q$). Thus,

$$\mathfrak{B}_{\lambda,\mu,p,q} = \{\varphi : [p] \to [q] \mid \mu = \varphi_* \lambda\} = \{\zeta : [p] \to [q] \mid \mu = \zeta_* \lambda\} \tag{13.46.90}$$

(here, we have renamed the index φ as ζ).

On the other hand, $p = \ell(\lambda)$. Hence, the definition of $\mathfrak{B}'_{\lambda,\mu}$ yields

$$\begin{aligned} \mathfrak{B}'_{\lambda,\mu} &= \left\{ \varphi : [p] \to \{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i \in [p]; \\ \varphi(i) = j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\} \right\} \\ &= \left\{ \zeta : [p] \to \{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i \in [p]; \\ \zeta(i) = j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\} \right\} \end{aligned} \tag{13.46.91}$$

(here, we have renamed the index φ as ζ).

But $[q] = \{1, 2, \ldots, q\} \subset \{1, 2, 3, \ldots\}$. Thus, Lemma 13.46.38 (applied to $X = [q]$, $Y = \{1, 2, 3, \ldots\}$ and $Z = [p]$) shows that the map

$$[q]^{[p]} \to \left\{ f \in \{1,2,3,\ldots\}^{[p]} \mid f([p]) \subset [q] \right\}, \\ g \mapsto g \mid^{\{1,2,3,\ldots\}}$$

is a bijection. Denote this bijection by Φ.

We have $\mathfrak{B}_{\lambda,\mu,p,q} = \{\varphi : [p] \to [q] \mid \mu = \varphi_* \lambda\} \subset \{\varphi : [p] \to [q]\} = [q]^{[p]}$. In other words, $\mathfrak{B}_{\lambda,\mu,p,q}$ is a subset of $[q]^{[p]}$. Thus, the image $\Phi(\mathfrak{B}_{\lambda,\mu,p,q})$ is well-defined.

The map Φ is bijective (since it is a bijection), and therefore injective.

If U and V are two finite sets, and if T is a subset of U, and if $\Psi : U \to V$ is an injective map, then $\Psi(T) \cong T$ as sets.[549] Applying this to $U = [q]^{[p]}$, $V = \left\{ f \in \{1,2,3,\ldots\}^{[p]} \mid f([p]) \subset [q] \right\}$, $T = \mathfrak{B}_{\lambda,\mu,p,q}$ and $\Psi = \Phi$, we conclude that

$$\Phi(\mathfrak{B}_{\lambda,\mu,p,q}) \cong \mathfrak{B}_{\lambda,\mu,p,q} \qquad \text{as sets} \tag{13.46.92}$$

[549] This is a basic fact about sets.

(since Φ is injective).

On the other hand, let $\varphi : [p] \to [q]$ be any map. Then,

$$\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{q+1, q+2, q+3, \ldots\} \tag{13.46.93}$$

[550].

Recall that $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p)$. Hence, the definition of $\varphi_* \lambda$ shows that

$$\varphi_* \lambda = \left(\sum_{i\in\varphi^{-1}\{1\}} \lambda_i, \sum_{i\in\varphi^{-1}\{2\}} \lambda_i, \ldots, \sum_{i\in\varphi^{-1}\{q\}} \lambda_i \right).$$

Thus, we have the following chain of logical equivalences:

$$\begin{aligned} &\left(\underbrace{\mu}_{=(\mu_1,\mu_2,\ldots,\mu_q)} = \underbrace{\varphi_*\lambda}_{=\left(\sum_{i\in\varphi^{-1}\{1\}}\lambda_i, \sum_{i\in\varphi^{-1}\{2\}}\lambda_i, \ldots, \sum_{i\in\varphi^{-1}\{q\}}\lambda_i\right)} \right) \\ \Longleftrightarrow\ & \left((\mu_1, \mu_2, \ldots, \mu_q) = \left(\sum_{i\in\varphi^{-1}\{1\}} \lambda_i, \sum_{i\in\varphi^{-1}\{2\}} \lambda_i, \ldots, \sum_{i\in\varphi^{-1}\{q\}} \lambda_i \right) \right) \\ \Longleftrightarrow\ & \left(\mu_j = \underbrace{\sum_{i\in\varphi^{-1}\{j\}}}_{=\sum_{\substack{i\in[p];\\ \varphi(i)=j}}} \lambda_i \text{ for all } j \in \{1, 2, \ldots, q\} \right) \\ \Longleftrightarrow\ & \left(\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1, 2, \ldots, q\} \right). \end{aligned} \tag{13.46.94}$$

Now, we have the following logical implication:

$$(\mu = \varphi_* \lambda) \implies \left(\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1, 2, 3, \ldots\} \right) \tag{13.46.95}$$

[551].

Now, forget that we fixed φ. We thus have proven the implication (13.46.95) for each map $\varphi : [p] \to [q]$.

[550] *Proof of (13.46.93):* Let $j \in \{q+1, q+2, q+3, \ldots\}$. Thus, $j \geq q+1$ and $\mu_j = 0$ (by (13.46.88)).

Let $i \in [p]$ be such that $\varphi(i) = j$. Thus, $j = \varphi(i) \in [q] = \{1, 2, \ldots, q\}$, so that $j \leq q$. This contradicts $j \geq q+1 > q$.

Now, forget that we fixed i. We thus have found a contradiction for each $i \in [p]$ satisfying $\varphi(i) = j$. Hence, there exists no $i \in [p]$ satisfying $\varphi(i) = j$. Thus, the sum $\sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i$ is empty. Hence, $\sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i = (\text{empty sum}) = 0$. Comparing this with $\mu_j = 0$, we obtain $\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i$. This proves (13.46.93).

[551] *Proof of (13.46.95):* Assume that $(\mu = \varphi_* \lambda)$ holds. We must show that $\left(\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1, 2, 3, \ldots\} \right)$ holds.

From the equivalence (13.46.94), we conclude that

$$\left(\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,\ldots,q\}\right) \tag{13.46.96}$$

holds (because $(\mu = \varphi_* \lambda)$ holds).

Now, let $j \in \{1,2,3,\ldots\}$. Then, we want to prove that $\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i$. If $j \in \{q+1, q+2, q+3, \ldots\}$, then this follows immediately from (13.46.93). Hence, for the rest of this proof, we WLOG assume that $j \notin \{q+1, q+2, q+3, \ldots\}$. Combining this with $j \in \{1,2,3,\ldots\}$, we obtain $j \in \{1,2,3,\ldots\} \setminus \{q+1, q+2, q+3, \ldots\} = \{1,2,\ldots,q\}$. Hence, from (13.46.96), we obtain $\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i$.

Now, forget that we fixed j. We thus have shown that $\left(\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}\right)$ holds. This concludes the proof of the implication (13.46.95).

Now, it is easy to see that $\Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right) \subset \mathfrak{B}'_{\lambda,\mu}$ [552] and $\mathfrak{B}'_{\lambda,\mu} \subset \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right)$ [553]. Combining these two inclusions, we obtain $\Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right) = \mathfrak{B}'_{\lambda,\mu}$. Hence,

$$\mathfrak{B}'_{\lambda,\mu} = \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right) \cong \mathfrak{B}_{\lambda,\mu,p,q} \qquad \text{as sets}$$

(by (13.46.92)). This proves Proposition 13.46.39. □

[552] *Proof.* Let $\psi \in \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right)$. Thus, $\psi \in \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right) \subset \left\{f \in \{1,2,3,\ldots\}^{[p]} \mid f([p]) \subset [q]\right\}$. In other words, ψ is an element of $\{1,2,3,\ldots\}^{[p]}$ and satisfies $\psi([p]) \subset [q]$.

But $\psi \in \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right)$. In other words, there exists some $\varphi \in \mathfrak{B}_{\lambda,\mu,p,q}$ such that $\psi = \Phi(\varphi)$. Consider this φ. We have $\psi = \Phi(\varphi) = \varphi \mid^{\{1,2,3,\ldots\}}$ (by the definition of Φ).

We have $\varphi \in \mathfrak{B}_{\lambda,\mu,p,q} = \{\zeta : [p] \to [q] \mid \mu = \zeta_* \lambda\}$ (by (13.46.90)). In other words, φ is a map $[p] \to [q]$ and satisfies $\mu = \varphi_* \lambda$.

Each $i \in [p]$ satisfies

$$\underbrace{\psi}_{=\varphi\mid^{\{1,2,3,\ldots\}}}(i) = \left(\varphi \mid^{\{1,2,3,\ldots\}}\right)(i) = \varphi(i) \tag{13.46.97}$$

(by the definition of $\varphi \mid^{\{1,2,3,\ldots\}}$).

We have $(\mu = \varphi_* \lambda)$. Hence, from the implication (13.46.95), we conclude that

$$\left(\mu_j = \sum_{\substack{i\in[p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}\right). \tag{13.46.98}$$

Now, each $j \in \{1,2,3,\ldots\}$ satisfies

$$\mu_j = \underbrace{\sum_{\substack{i\in[p];\\ \varphi(i)=j}}}_{\substack{=\sum_{\substack{i\in[p];\\ \psi(i)=j}} \\ \text{(because every } i\in[p] \text{ satisfies } \varphi(i)=\psi(i) \\ \text{(by (13.46.97)))}}} \lambda_i \qquad \text{(by (13.46.98))}$$
$$= \sum_{\substack{i\in[p];\\ \psi(i)=j}} \lambda_i.$$

In other words, we have $\left(\mu_j = \sum_{\substack{i\in[p];\\ \psi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}\right)$.

Now, ψ is a map $[p] \to \{1,2,3,\ldots\}$ (since ψ is an element of $\{1,2,3,\ldots\}^{[p]}$) and satisfies $\left(\mu_j = \sum_{\substack{i\in[p];\\ \psi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}\right)$. In other words,

$$\psi \in \left\{\zeta : [p] \to \{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i\in[p];\\ \zeta(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}\right\}.$$

In light of (13.46.91), this rewrites as $\psi \in \mathfrak{B}'_{\lambda,\mu}$.

Now, forget that we fixed ψ. We thus have proven that $\psi \in \mathfrak{B}'_{\lambda,\mu}$ for each $\psi \in \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right)$. In other words, $\Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right) \subset \mathfrak{B}'_{\lambda,\mu}$. Qed.

[553] *Proof.* Let $\psi \in \mathfrak{B}'_{\lambda,\mu}$. Thus, $\psi \in \mathfrak{B}'_{\lambda,\mu} = \left\{\zeta : [p] \to \{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i\in[p];\\ \zeta(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}\right\}$ (by (13.46.91)). In other words, ψ is a map $[p] \to \{1,2,3,\ldots\}$ and satisfies

$$\left(\mu_j = \sum_{\substack{i\in[p];\\ \psi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}\right). \tag{13.46.99}$$

Now, let $k \in [p]$. We shall show that $\psi(k) \in [q]$.

Proposition 13.46.40. *Let $n \in \mathbb{N}$. Let $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$. Assume that $\mathfrak{B}'_{\lambda,\mu} \neq \varnothing$. Then, $\mu \rhd \lambda$.*

Proof of Proposition 13.46.40. Let $\ell = \ell(\lambda)$. We have $\mathfrak{B}'_{\lambda,\mu} \neq \varnothing$. In other words, there exists some $\psi \in \mathfrak{B}'_{\lambda,\mu}$. Consider this ψ. We have

$$\psi = \mathfrak{B}'_{\lambda,\mu} = \left\{ \varphi : [\ell] \to \{1,2,3,\ldots\} \ \mid \ \mu_j = \sum_{\substack{i \in [\ell];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\} \right\}$$

Indeed, assume the contrary. Thus, $\psi(k) \notin [q]$. Set $j = \psi(k)$. Combining $j = \psi(k) \in \{1,2,3,\ldots\}$ with $j = \psi(k) \notin [q] = \{1,2,\ldots,q\}$, we obtain $j \in \{1,2,3,\ldots\} \setminus \{1,2,\ldots,q\} = \{q+1, q+2, q+3, \ldots\}$. Hence, $j \geq q+1$ and $\mu_j = 0$ (by (13.46.88)).

But k is an element of $[p]$ and satisfies $\psi(k) = j$ (since $j = \psi(k)$). Hence, the sum $\sum_{\substack{i \in [p];\\ \psi(i)=j}} \lambda_i$ has an addend for $i = k$. If we split off this addend from this sum, then we obtain

$$\sum_{\substack{i \in [p];\\ \psi(i)=j}} \lambda_i = \lambda_k + \sum_{\substack{i \in [p];\\ \psi(i)=j;\\ i \neq k}} \underbrace{\lambda_i}_{\substack{\geq 0\\ (\text{since } \lambda_i \in \mathbb{N})}} \geq \lambda_k + \underbrace{\sum_{\substack{i \in [p];\\ \psi(i)=j;\\ i \neq k}} 0}_{=0} = \lambda_k > 0 \qquad (\text{by (13.46.89)}).$$

Hence, (13.46.99) yields $\mu_j = \sum_{\substack{i \in [p];\\ \psi(i)=j}} \lambda_i > 0$. This contradicts $\mu_j = 0$.

This contradiction completes our proof of $\psi(k) \in [q]$.

Now, forget that we fixed k. We thus have proven that $\psi(k) \in [q]$ for each $k \in [p]$. In other words, $\psi([p]) \subset [q]$.

Altogether, we know that ψ is an element of $\{1,2,3,\ldots\}^{[p]}$ (since ψ is a map $[p] \to \{1,2,3,\ldots\}$) and satisfies $\psi([p]) \subset [q]$. In other words, $\psi \in \left\{ f \in \{1,2,3,\ldots\}^{[p]} \ \mid \ f([p]) \subset [q] \right\}$. Hence, an element $\Phi^{-1}(\psi) \in [q]^{[p]}$ is well-defined (since Φ is a bijection $[q]^{[p]} \to \left\{ f \in \{1,2,3,\ldots\}^{[p]} \ \mid \ f([p]) \subset [q] \right\}$). Let us denote this element $\Phi^{-1}(\psi)$ by φ. Thus, $\varphi = \Phi^{-1}(\psi) \in [q]^{[p]}$. In other words, φ is a map $[p] \to [q]$.

From $\varphi = \Phi^{-1}(\psi)$, we obtain $\psi = \Phi(\varphi) = \varphi\mid^{\{1,2,3,\ldots\}}$ (by the definition of Φ).

Each $i \in [p]$ satisfies

$$\underbrace{\psi}_{=\varphi\mid^{\{1,2,3,\ldots\}}} (i) = \left(\varphi \mid^{\{1,2,3,\ldots\}} \right)(i) = \varphi(i) \tag{13.46.100}$$

(by the definition of $\varphi\mid^{\{1,2,3,\ldots\}}$).

Now, each $j \in \{1,2,\ldots,q\}$ satisfies

$$\begin{aligned} \mu_j &= \underbrace{\sum_{\substack{i \in [p];\\ \psi(i)=j}}}_{\substack{=\sum_{\substack{i\in[p];\\ \varphi(i)=j}}\\ (\text{because every } i \in [p] \text{ satisfies } \psi(i)=\varphi(i)\\ (\text{by } (13.46.100)))}} \lambda_i \qquad (\text{by (13.46.99)}) \\ &= \sum_{\substack{i \in [p];\\ \varphi(i)=j}} \lambda_i . \end{aligned}$$

In other words, we have $\left(\mu_j = \sum_{\substack{i \in [p];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,\ldots,q\} \right)$. Hence, the equivalence (13.46.94) shows that $(\mu = \varphi_* \lambda)$.

Altogether, we now know that φ is a map $[p] \to [q]$ and satisfies $\mu = \varphi_* \lambda$. In other words, $\varphi \in \{\zeta : [p] \to [q] \ \mid \ \mu = \zeta_* \lambda\}$. In light of (13.46.90), this rewrites as $\varphi \in \mathfrak{B}_{\lambda,\mu,p,q}$. Hence, $\psi = \Phi\left(\underbrace{\varphi}_{\in \mathfrak{B}_{\lambda,\mu,p,q}} \right) \in \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right)$.

Now, forget that we fixed ψ. We thus have proven that $\psi \in \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right)$ for each $\psi \in \mathfrak{B}'_{\lambda,\mu}$. In other words, $\mathfrak{B}'_{\lambda,\mu} \subset \Phi\left(\mathfrak{B}_{\lambda,\mu,p,q}\right)$. Qed.

(by the definition of $\mathfrak{B}'_{\lambda,\mu}$ (since $\ell = \ell(\lambda)$)). In other words, ψ is a map $[\ell] \to \{1, 2, 3, \ldots\}$ and satisfies

$$\left(\mu_j = \sum_{\substack{i\in[\ell];\\ \psi(i)=j}} \lambda_i \text{ for all } j \in \{1, 2, 3, \ldots\}\right). \tag{13.46.101}$$

Let $k \in \{1, 2, \ldots, \ell\}$. Then, $1 \leq k \leq \ell$. Hence, $[k]$ is a subset of $[\ell]$.

Define a subset R of $\{1, 2, 3, \ldots\}$ by $R = \psi([k])$. This set $R = \psi([k])$ is finite (since $[k]$ is finite).

Each $i \in \{1, 2, \ldots, k\}$ satisfies

$$\sum_{\substack{j\in R;\\ \psi(i)=j}} \lambda_i = \lambda_i \tag{13.46.102}$$

[554].

It is well-known that if X and Y are two sets, if $f : X \to Y$ is any map, and if T is a finite subset of X, then $|f(T)| \leq |T|$. Applying this to $X = [\ell]$, $Y = \{1, 2, 3, \ldots\}$, $f = \psi$ and $T = [k]$, we conclude that $|\psi([k])| \leq |[k]| = k$. In light of $R = \psi([k])$, this rewrites as $|R| \leq k$.

We know that μ is a partition; thus, $\mu_1 \geq \mu_2 \geq \mu_3 \geq \cdots$. Moreover, $\mu \in \operatorname{Par} \subset \mathbb{N}^\infty$. Hence, $(\mu_1, \mu_2, \mu_3, \ldots) = \mu \in \mathbb{N}^\infty$. Thus, Lemma 13.46.32 (applied to $\beta_i = \mu_i$) yields $\sum_{r\in R} \mu_r \leq \mu_1 + \mu_2 + \cdots + \mu_k$. Hence,

$$\begin{aligned}
\mu_1 + \mu_2 + \cdots + \mu_k &\geq \sum_{r\in R} \mu_r \\
&= \sum_{j\in R} \underbrace{\mu_j}_{\substack{=\sum_{\substack{i\in[\ell];\\ \psi(i)=j}} \lambda_i \\ \text{(by (13.46.101))}}} \qquad \text{(here, we have renamed the summation index } r \text{ as } j\text{)} \\
&= \underbrace{\sum_{j\in R} \sum_{\substack{i\in[\ell];\\ \psi(i)=j}}}_{=\sum_{i\in[\ell]} \sum_{\substack{j\in R;\\ \psi(i)=j}}} \lambda_i = \underbrace{\sum_{i\in[\ell]}}_{=\sum_{i=1}^{\ell}} \sum_{\substack{j\in R;\\ \psi(i)=j}} \lambda_i \\
&= \sum_{i=1}^{\ell} \sum_{\substack{j\in R;\\ \psi(i)=j}} \lambda_i = \sum_{i=1}^{k} \underbrace{\sum_{\substack{j\in R;\\ \psi(i)=j}} \lambda_i}_{\substack{=\lambda_i \\ \text{(by (13.46.102))}}} + \sum_{i=k+1}^{\ell} \sum_{\substack{j\in R;\\ \psi(i)=j}} \underbrace{\lambda_i}_{\substack{\geq 0 \\ \text{(since } \lambda_i\in\mathbb{N})}} \\
&\qquad \text{(here, we have split the outer sum at } i = k\text{, because } 1 \leq k \leq \ell\text{)} \\
&\geq \sum_{i=1}^{k} \lambda_i + \underbrace{\sum_{i=k+1}^{\ell} \sum_{\substack{j\in R;\\ \psi(i)=j}} 0}_{=0} = \sum_{i=1}^{k} \lambda_i = \lambda_1 + \lambda_2 + \cdots + \lambda_k.
\end{aligned}$$

[554] *Proof of (13.46.102):* Let $i \in \{1, 2, \ldots, k\}$. Thus, $i \in \{1, 2, \ldots, k\} = [k]$. Hence, $\psi\left(\underbrace{i}_{\in[k]}\right) \in \psi([k]) = R$. Thus, there exists a $j \in R$ satisfying $j = \psi(i)$ (namely, $j = \psi(i)$). This j is furthermore unique (since the condition $j = \psi(i)$ determines j uniquely). Thus, there exists **exactly one** $j \in R$ satisfying $\psi(i) = j$ (namely, $j = \psi(i)$). Hence, the sum $\sum_{\substack{j\in R;\\ \psi(i)=j}} \lambda_i$ has exactly one addend (namely, the addend for $j = \psi(i)$). Thus, this sum simplifies as follows: $\sum_{\substack{j\in R;\\ \psi(i)=j}} \lambda_i = \lambda_i$. This proves (13.46.102).

Now, let us forget that we fixed k. We thus have shown that $\mu_1+\mu_2+\cdots+\mu_k \geq \lambda_1+\lambda_2+\cdots+\lambda_k$ for each $k \in \{1,2,\ldots,\ell\}$. Therefore, Lemma 13.46.20 (applied to ℓ, λ and μ instead of q, μ and λ) yields $\mu \trianglerighteq \lambda$ (since $\ell(\lambda)=\ell\leq\ell$). This proves Proposition 13.46.40. □

Proposition 13.46.41. *Let $\mu \in \operatorname{Par}$. Let $k=\ell(\mu)$. Then:*

(a) *We have $\mathfrak{B}_{\mu,\mu,k,k}=\left\{\sigma\in\mathfrak{S}_k \mid \mu_{\sigma(i)}=\mu_i \text{ for each } i\in[k]\right\}$.*

(b) *The set $\mathfrak{B}_{\mu,\mu,k,k}$ is a subgroup of $\mathfrak{S}_k$.*

Proof of Proposition 13.46.41. We know that $\mathfrak{S}_k$ is the set of all permutations of $\{1,2,\ldots,k\}$. In other words, $\mathfrak{S}_k$ is the set of all permutations of $[k]$ (since $[k]=\{1,2,\ldots,k\}$).

Recall that $\ell(\mu)=k$. Thus, $\mu=(\mu_1,\mu_2,\ldots,\mu_k)\in\mathbb{N}^k$. Also, from $\ell(\mu)=k$, we obtain $\mu_1\geq\mu_2\geq\cdots\geq\mu_k>0$ (by the definition of $\ell(\mu)$). Hence,

$$\mu_i>0 \qquad \text{for each } i\in[k]. \tag{13.46.103}$$

The definition of $\mathfrak{B}_{\mu,\mu,k,k}$ yields

$$\mathfrak{B}_{\mu,\mu,k,k}=\{\varphi:[k]\to[k] \mid \mu=\varphi_*\mu\}, \tag{13.46.104}$$

where μ is regarded as the k-tuple $(\mu_1,\mu_2,\ldots,\mu_k)\in\mathbb{N}^k$.

We have $\mathfrak{B}_{\mu,\mu,k,k}\subset\mathfrak{S}_k$ [555]. Hence, we have the two inclusions $\mathfrak{B}_{\mu,\mu,k,k}\subset\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}$ [556] and $\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}\subset\mathfrak{B}_{\mu,\mu,k,k}$ [557]. Combining these two inclusions, we obtain

$$\mathfrak{B}_{\mu,\mu,k,k}=\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}. \tag{13.46.105}$$

But let $\sigma\in\mathfrak{S}_k$ be arbitrary. Then, Proposition 13.46.29(b) (applied to $p=k$, $\alpha=\mu$ and $\alpha_i=\mu_i$) shows that we have $\sigma_*\mu=\mu$ if and only if $\left(\mu_{\sigma(i)}=\mu_i \text{ for all } i\in[k]\right)$. In other words, we have the following logical equivalence:

$$(\sigma_*\mu=\mu)\iff\left(\mu_{\sigma(i)}=\mu_i \text{ for all } i\in[k]\right). \tag{13.46.106}$$

Now, forget that we fixed σ. We thus have proven the equivalence (13.46.106) for each $\sigma\in\mathfrak{S}_k$.

Now, the equality (13.46.105) becomes

$$\mathfrak{B}_{\mu,\mu,k,k}=\left\{\sigma\in\mathfrak{S}_k \mid \underbrace{\sigma_*\mu=\mu}_{\substack{\iff\left(\mu_{\sigma(i)}=\mu_i \text{ for all } i\in[k]\right)\\ \text{(by (13.46.106))}}}\right\}=\left\{\sigma\in\mathfrak{S}_k \mid \mu_{\sigma(i)}=\mu_i \text{ for each } i\in[k]\right\}.$$

This proves Proposition 13.46.41(a).

(b) The neutral element of the group $\mathfrak{S}_k$ is $\operatorname{id}_{\{1,2,\ldots,k\}}=\operatorname{id}_{[k]}$ (since $\{1,2,\ldots,k\}=[k]$).

The following four observations hold:

[555] *Proof.* Let $\psi\in\mathfrak{B}_{\mu,\mu,k,k}$. Thus, $\psi\in\mathfrak{B}_{\mu,\mu,k,k}=\{\varphi:[k]\to[k] \mid \mu=\varphi_*\mu\}$. In other words, ψ is a map $[k]\to[k]$ and satisfies $\mu=\psi_*\mu$. Thus, $\psi_*\mu=\mu$.

But Lemma 13.46.31 (applied to $p=k$, $q=k$, $\varphi=\psi$, $\alpha=\mu$, $\alpha_i=\mu_i$, $\beta=\mu$ and $\beta_i=\mu_i$) shows that the map ψ is surjective (because (13.46.103) shows that ($\mu_i>0$ for each $i\in[k]$)). Hence, ψ is a surjective map $[k]\to[k]$.

Now, recall the following known fact about finite sets: If T is a finite set, then each surjective map $T\to T$ is bijective. Applying this fact to $T=[k]$, we conclude that each surjective map $[k]\to[k]$ is bijective (since $[k]$ is a finite set). Thus, the map ψ is bijective (since ψ is a surjective map $[k]\to[k]$). Thus, ψ is a bijection $[k]\to[k]$. In other words, ψ is a permutation of $[k]$. In other words, $\psi\in\mathfrak{S}_k$ (since $\mathfrak{S}_k$ is the set of all permutations of $[k]$).

Now, forget that we fixed ψ. We thus have shown that $\psi\in\mathfrak{S}_k$ for each $\psi\in\mathfrak{B}_{\mu,\mu,k,k}$. In other words, $\mathfrak{B}_{\mu,\mu,k,k}\subset\mathfrak{S}_k$. Qed.

[556] *Proof.* Let $\psi\in\mathfrak{B}_{\mu,\mu,k,k}$. Thus, $\psi\in\mathfrak{B}_{\mu,\mu,k,k}=\{\varphi:[k]\to[k] \mid \mu=\varphi_*\mu\}$. In other words, ψ is a map $[k]\to[k]$ and satisfies $\mu=\psi_*\mu$. Thus, $\psi_*\mu=\mu$. Also, $\psi\in\mathfrak{B}_{\mu,\mu,k,k}\subset\mathfrak{S}_k$. Hence, ψ is an element of $\mathfrak{S}_k$ and satisfies $\psi_*\mu=\mu$. In other words, $\psi\in\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}$.

Now, forget that we fixed ψ. We thus have shown that $\psi\in\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}$ for each $\psi\in\mathfrak{B}_{\mu,\mu,k,k}$. In other words, $\mathfrak{B}_{\mu,\mu,k,k}\subset\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}$. Qed.

[557] *Proof.* Let $\psi\in\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}$. Thus, ψ is an element of $\mathfrak{S}_k$ and satisfies $\psi_*\mu=\mu$.

We know that ψ is an element of $\mathfrak{S}_k$. In other words, ψ is a permutation of $[k]$ (since $\mathfrak{S}_k$ is the set of all permutations of $[k]$). In other words, ψ is a bijection $[k]\to[k]$.

Thus, ψ is a map $[k]\to[k]$ and satisfies $\mu=\psi_*\mu$ (since $\psi_*\mu=\mu$). In other words, $\psi\in\{\varphi:[k]\to[k] \mid \mu=\varphi_*\mu\}$. In light of (13.46.104), this rewrites as $\psi\in\mathfrak{B}_{\mu,\mu,k,k}$.

Now, forget that we fixed ψ. We thus have proven that $\psi\in\mathfrak{B}_{\mu,\mu,k,k}$ for each $\psi\in\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}$. In other words, $\{\sigma\in\mathfrak{S}_k \mid \sigma_*\mu=\mu\}\subset\mathfrak{B}_{\mu,\mu,k,k}$. Qed.

- The set $\mathfrak{B}_{\mu,\mu,k,k}$ is a subset of $\mathfrak{S}_k$ (since $\mathfrak{B}_{\mu,\mu,k,k} \subset \mathfrak{S}_k$).
- If γ and δ are two elements of $\mathfrak{B}_{\mu,\mu,k,k}$, then $\gamma \circ \delta \in \mathfrak{B}_{\mu,\mu,k,k}$ [558].
- We have $\operatorname{id}_{[k]} \in \mathfrak{B}_{\mu,\mu,k,k}$ [559].
- If $\gamma \in \mathfrak{B}_{\mu,\mu,k,k}$, then $\gamma^{-1} \in \mathfrak{B}_{\mu,\mu,k,k}$ [560].

Combining these four observations, we conclude that $\mathfrak{B}_{\mu,\mu,k,k}$ is a subgroup of $\mathfrak{S}_k$ (since the neutral element of the group $\mathfrak{S}_k$ is $\operatorname{id}_{[k]}$). This proves Proposition 13.46.41(b). □

Proposition 13.46.42. *Let $p \in \mathbb{N}$. Let $\varphi : [p] \to \{1, 2, 3, \ldots\}$ be any map. Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p) \in \mathbb{N}^p$ be a p-tuple. Then,*

$$\left(\sum_{i \in \varphi^{-1}\{1\}} \alpha_i, \sum_{i \in \varphi^{-1}\{2\}} \alpha_i, \sum_{i \in \varphi^{-1}\{3\}} \alpha_i, \ldots \right)$$

is a weak composition.

Proof of Proposition 13.46.42. For each $j \in \{1, 2, 3, \ldots\}$, the sum $\sum_{i \in \varphi^{-1}\{j\}} \alpha_i$ is a well-defined element of $\mathbb{N}$ [561]. Hence, the sequence

$$\left(\sum_{i \in \varphi^{-1}\{1\}} \alpha_i, \sum_{i \in \varphi^{-1}\{2\}} \alpha_i, \sum_{i \in \varphi^{-1}\{3\}} \alpha_i, \ldots \right)$$

is a well-defined element of $\mathbb{N}^\infty$. Denote this sequence by β. We shall now show that this sequence β is a weak composition.

Write the sequence β in the form $\beta = (\beta_1, \beta_2, \beta_3, \ldots)$. Thus,

$$(\beta_1, \beta_2, \beta_3, \ldots) = \beta = \left(\sum_{i \in \varphi^{-1}\{1\}} \alpha_i, \sum_{i \in \varphi^{-1}\{2\}} \alpha_i, \sum_{i \in \varphi^{-1}\{3\}} \alpha_i, \ldots \right).$$

In other words,

$$\beta_j = \sum_{i \in \varphi^{-1}\{j\}} \alpha_i \qquad \text{for each } j \in \{1, 2, 3, \ldots\}. \tag{13.46.107}$$

[558] *Proof.* Let γ and δ be two elements of $\mathfrak{B}_{\mu,\mu,k,k}$. We must prove that $\gamma \circ \delta \in \mathfrak{B}_{\mu,\mu,k,k}$.

We have $\gamma \in \mathfrak{B}_{\mu,\mu,k,k} = \{\varphi : [k] \to [k] \mid \mu = \varphi_* \mu\}$ (by (13.46.104)). In other words, γ is a map $[k] \to [k]$ and satisfies $\mu = \gamma_* \mu$. The same argument (applied to δ instead of γ) shows that δ is a map $[k] \to [k]$ and satisfies $\mu = \delta_* \mu$. Now, Proposition 13.46.28 (applied to $p = k$, $q = k$, $r = k$, $\psi = \gamma$, $\varphi = \delta$ and $\alpha = \mu$) yields $(\gamma \circ \delta)_* \mu = \gamma_* \left(\underbrace{\delta_* \mu}_{= \mu} \right) = \gamma_* \mu = \mu$. In other words, $\mu = (\gamma \circ \delta)_* \mu$. Hence, $\gamma \circ \delta$ is a map $[k] \to [k]$ (since γ and δ are maps $[k] \to [k]$) and satisfies $\mu = (\gamma \circ \delta)_* \mu$. In other words, $\gamma \circ \delta \in \{\varphi : [k] \to [k] \mid \mu = \varphi_* \mu\}$. In light of (13.46.104), this rewrites as $\gamma \circ \delta \in \mathfrak{B}_{\mu,\mu,k,k}$. Qed.

[559] *Proof.* Proposition 13.46.30 (applied to $p = k$ and $\alpha = \mu$) yields $\left(\operatorname{id}_{[k]}\right)_* \mu = \mu$. Hence, $\mu = \left(\operatorname{id}_{[k]}\right)_* \mu$.

Thus, $\operatorname{id}_{[k]}$ is a map $[k] \to [k]$ and satisfies $\mu = \left(\operatorname{id}_{[k]}\right)_* \mu$. In other words, $\operatorname{id}_{[k]} \in \{\varphi : [k] \to [k] \mid \mu = \varphi_* \mu\}$. In light of (13.46.104), this rewrites as $\operatorname{id}_{[k]} \in \mathfrak{B}_{\mu,\mu,k,k}$. Qed.

[560] *Proof.* Let $\gamma \in \mathfrak{B}_{\mu,\mu,k,k}$. We must prove that $\gamma^{-1} \in \mathfrak{B}_{\mu,\mu,k,k}$.

We have $\gamma \in \mathfrak{B}_{\mu,\mu,k,k} = \{\varphi : [k] \to [k] \mid \mu = \varphi_* \mu\}$ (by (13.46.104)). In other words, γ is a map $[k] \to [k]$ and satisfies $\mu = \gamma_* \mu$. Also, $\gamma \in \mathfrak{B}_{\mu,\mu,k,k} \subset \mathfrak{S}_k$; therefore, γ has an inverse γ^{-1} (since $\mathfrak{S}_k$ is a group). Proposition 13.46.28 (applied to $p = k$, $q = k$, $r = k$, $\psi = \gamma^{-1}$, $\varphi = \gamma$ and $\alpha = \mu$) yields $\left(\gamma^{-1} \circ \gamma\right)_* \mu = \left(\gamma^{-1}\right)_* \left(\underbrace{\gamma_* \mu}_{= \mu} \right) = \left(\gamma^{-1}\right)_* \mu$. Hence, $\left(\gamma^{-1}\right)_* \mu = \left(\underbrace{\gamma^{-1} \circ \gamma}_{= \operatorname{id}_{[k]}} \right)_* \mu = \left(\operatorname{id}_{[k]}\right)_* \mu$.

But Proposition 13.46.30 (applied to $p = k$ and $\alpha = \mu$) yields $\left(\operatorname{id}_{[k]}\right)_* \mu = \mu$. Hence, $\mu = \left(\operatorname{id}_{[k]}\right)_* \mu$. Comparing this with $\left(\gamma^{-1}\right)_* \mu = \left(\operatorname{id}_{[k]}\right)_* \mu$, we obtain $\mu = \left(\gamma^{-1}\right)_* \mu$. Hence, γ^{-1} is a map $[k] \to [k]$ (since γ is a map $[k] \to [k]$) and satisfies $\mu = \left(\gamma^{-1}\right)_* \mu$. In other words, $\gamma^{-1} \in \{\varphi : [k] \to [k] \mid \mu = \varphi_* \mu\}$. In light of (13.46.104), this rewrites as $\gamma^{-1} \in \mathfrak{B}_{\mu,\mu,k,k}$. Qed.

[561] *Proof.* Let $j \in \{1, 2, 3, \ldots\}$. Then, $\varphi^{-1}\{j\}$ is a subset of $[p]$, and thus a finite set (since $[p]$ is a finite set). Hence, the sum $\sum_{i \in \varphi^{-1}\{j\}} \alpha_i$ is well-defined. Moreover, this sum belongs to $\mathbb{N}$ (since each of its addends α_i belongs to $\mathbb{N}$). Thus, the sum $\sum_{i \in \varphi^{-1}\{j\}} \alpha_i$ is a well-defined element of $\mathbb{N}$. Qed.

Let Z be the support of the sequence β. Then,

$$\begin{aligned}Z &= (\text{the support of the sequence } \beta)\\ &= (\text{the set of all positive integers } i \text{ for which } \beta_i \neq 0)\\ &\qquad (\text{by the definition of the support of a sequence})\\ &= \{i \in \{1,2,3,\ldots\} \ \mid \ \beta_i \neq 0\}.\end{aligned}$$

Every $j \in Z$ satisfies $j \in \varphi([p])$ [562]. In other words, we have $Z \subset \varphi([p])$. Hence, the set Z is finite (since the set $\varphi([p])$ is finite (since the set $[p]$ is finite)). In other words, the support of the sequence β is finite (since Z is the support of the sequence β).

Hence, we know that β is a sequence in $\mathbb{N}^\infty$ having finite support. In other words, β is a weak composition (since a weak composition is defined as a sequence in $\mathbb{N}^\infty$ having finite support). In other words,

$$\left(\sum_{i\in\varphi^{-1}\{1\}} \alpha_i, \sum_{i\in\varphi^{-1}\{2\}} \alpha_i, \sum_{i\in\varphi^{-1}\{3\}} \alpha_i, \ldots\right)$$

is a weak composition (since $\beta = \left(\sum_{i\in\varphi^{-1}\{1\}} \alpha_i, \sum_{i\in\varphi^{-1}\{2\}} \alpha_i, \sum_{i\in\varphi^{-1}\{3\}} \alpha_i, \ldots\right)$). This proves Proposition 13.46.42. □

Proposition 13.46.42 allows us to make the following definition (which is similar to Definition 13.46.26, but uses the infinite set $\{1,2,3,\ldots\}$ instead of $[q]$):

Definition 13.46.43. Let $p \in \mathbb{N}$. Let $\varphi : [p] \to \{1,2,3,\ldots\}$ be any map. Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p) \in \mathbb{N}^p$ be a p-tuple. Then, we define a weak composition $\varphi_*\alpha \in \operatorname{WC}$ by

$$\varphi_*\alpha = \left(\sum_{i\in\varphi^{-1}\{1\}} \alpha_i, \sum_{i\in\varphi^{-1}\{2\}} \alpha_i, \sum_{i\in\varphi^{-1}\{3\}} \alpha_i, \ldots\right).$$

(This is indeed a weak composition, because of Proposition 13.46.42.)

Proposition 13.46.44. *Let $p \in \mathbb{N}$. Let $\varphi : [p] \to \{1,2,3,\ldots\}$ be any map. Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_p) \in \mathbb{N}^p$ be a p-tuple. Then, $\mathbf{x}^{\varphi_*\alpha} = x_{\varphi(1)}^{\alpha_1} x_{\varphi(2)}^{\alpha_2} \cdots x_{\varphi(p)}^{\alpha_p}$.*

Proof of Proposition 13.46.44. The definition of $\varphi_*\alpha$ yields

$$\varphi_*\alpha = \left(\sum_{i\in\varphi^{-1}\{1\}} \alpha_i, \sum_{i\in\varphi^{-1}\{2\}} \alpha_i, \sum_{i\in\varphi^{-1}\{3\}} \alpha_i, \ldots\right).$$

[562] *Proof.* Let $j \in Z$. We must show that $j \in \varphi([p])$.

We have $j \in Z = \{i \in \{1,2,3,\ldots\} \ \mid \ \beta_i \neq 0\}$. In other words, j is an element of $\{1,2,3,\ldots\}$ and satisfies $\beta_j \neq 0$.

Assume (for the sake of contradiction) that $\varphi^{-1}\{j\} = \varnothing$. Thus, $\sum_{i\in\varphi^{-1}\{j\}} \alpha_i = \sum_{i\in\varnothing} \alpha_i = (\text{empty sum}) = 0$. Hence, (13.46.107) yields $\beta_j = \sum_{i\in\varphi^{-1}\{j\}} \alpha_i = 0$. This contradicts $\beta_j \neq 0$.

This contradiction shows that our assumption (that $\varphi^{-1}\{j\} = \varnothing$) was false. Hence, we must have $\varphi^{-1}\{j\} \neq \varnothing$. In other words, there exists some $k \in \varphi^{-1}\{j\}$. Consider this k.

From $k \in \varphi^{-1}\{j\}$, we obtain $\varphi(k) \in \{j\}$. Hence, $\varphi(k) = j$. Therefore, $j = \varphi\left(\underbrace{k}_{\in\varphi^{-1}\{j\}\subset[p]}\right) \in \varphi([p])$. This completes our proof.

Hence, the definition of $\mathbf{x}^{\varphi_*\alpha}$ shows that

$$\mathbf{x}^{\varphi_*\alpha} = x_1^{\sum_{i\in\varphi^{-1}\{1\}}\alpha_i} x_2^{\sum_{i\in\varphi^{-1}\{2\}}\alpha_i} x_3^{\sum_{i\in\varphi^{-1}\{3\}}\alpha_i} \cdots = \underbrace{\prod_{j=1}^{\infty}}_{=\prod_{j\in\{1,2,3,\ldots\}}} \underbrace{x_j^{\sum_{i\in\varphi^{-1}\{j\}}\alpha_i}}_{=\prod_{i\in\varphi^{-1}\{j\}} x_j^{\alpha_i}}$$

$$= \prod_{j\in\{1,2,3,\ldots\}} \underbrace{\prod_{i\in\varphi^{-1}\{j\}}}_{=\prod_{\substack{i\in[p];\\ \varphi(i)=j}}} x_j^{\alpha_i} = \prod_{j\in\{1,2,3,\ldots\}} \prod_{\substack{i\in[p];\\ \varphi(i)=j}} x_j^{\alpha_i}.$$

Comparing this with

$$x_{\varphi(1)}^{\alpha_1} x_{\varphi(2)}^{\alpha_2} \cdots x_{\varphi(p)}^{\alpha_p} = \underbrace{\prod_{i\in[p]}}_{\substack{=\prod_{j\in\{1,2,3,\ldots\}} \prod_{\substack{i\in[p];\\ \varphi(i)=j}} \\ (\text{since } \varphi(i)\in\{1,2,3,\ldots\} \text{ for each } i\in[p])}} x_{\varphi(i)}^{\alpha_i} = \prod_{j\in\{1,2,3,\ldots\}} \prod_{\substack{i\in[p];\\ \varphi(i)=j}} \underbrace{x_{\varphi(i)}^{\alpha_i}}_{\substack{=x_j^{\alpha_i} \\ (\text{since } \varphi(i)=j)}}$$

$$= \prod_{j\in\{1,2,3,\ldots\}} \prod_{\substack{i\in[p];\\ \varphi(i)=j}} x_j^{\alpha_i},$$

we obtain $\mathbf{x}^{\varphi_*\alpha} = x_{\varphi(1)}^{\alpha_1} x_{\varphi(2)}^{\alpha_2} \cdots x_{\varphi(p)}^{\alpha_p}$. This proves Proposition 13.46.44. □

Lemma 13.46.45. *Let $\ell \in \mathbb{N}$. Let X be a set. Then, the map*

$$X^{\{1,2,\ldots,\ell\}} \to X^\ell, \qquad \varphi \mapsto (\varphi(1), \varphi(2), \ldots, \varphi(\ell))$$

is a bijection.

Proof of Lemma 13.46.45. It is well-known that the ℓ-tuples of elements of X are in bijection with the maps $\{1, 2, \ldots, \ell\} \to X$ [563]. Lemma 13.46.45 is merely a way to precisely formulate this bijection. Thus, we omit its proof. □

Proposition 13.46.46. *Let $\ell \in \mathbb{N}$. Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_\ell) \in \mathbb{N}^\ell$ be such that ($\alpha_i > 0$ for each $i \in [\ell]$). Then,*

$$p_{\alpha_1} p_{\alpha_2} \cdots p_{\alpha_\ell} = \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \mathbf{x}^{\varphi_*\alpha}$$

in $\mathbf{k}[[\mathbf{x}]]$.

Proof of Proposition 13.46.46. We assumed that ($\alpha_i > 0$ for each $i \in [\ell]$). Thus, each $i \in [\ell]$ satisfies $\alpha_i > 0$ and therefore

$$p_{\alpha_i} = x_1^{\alpha_i} + x_2^{\alpha_i} + x_3^{\alpha_i} + \cdots \qquad (\text{by the definition of } p_{\alpha_i})$$

$$= \sum_{j\in\{1,2,3,\ldots\}} x_j^{\alpha_i}. \tag{13.46.108}$$

Lemma 13.46.45 (applied to $X = \{1, 2, 3, \ldots\}$) shows that the map

$$\{1,2,3,\ldots\}^{\{1,2,\ldots,\ell\}} \to \{1,2,3,\ldots\}^\ell, \qquad \varphi \mapsto (\varphi(1), \varphi(2), \ldots, \varphi(\ell))$$

is a bijection. In view of $[\ell] = \{1, 2, \ldots, \ell\}$, this rewrites as follows: The map

$$\{1,2,3,\ldots\}^{[\ell]} \to \{1,2,3,\ldots\}^\ell, \qquad \varphi \mapsto (\varphi(1), \varphi(2), \ldots, \varphi(\ell)) \tag{13.46.109}$$

is a bijection.

[563] In fact, depending on your definition of an "ℓ-tuple", you might even consider the ℓ-tuples of elements of X to be **exactly** the maps $\{1, 2, \ldots, \ell\} \to X$.

Now,

$$\begin{aligned}
p_{\alpha_1} p_{\alpha_2} \cdots p_{\alpha_\ell} &= \prod_{i=1}^{\ell} \underbrace{p_{\alpha_i}}_{\substack{=\sum_{j\in\{1,2,3,\ldots\}} x_j^{\alpha_i} \\ \text{(by (13.46.108))}}} = \prod_{i=1}^{\ell} \sum_{j\in\{1,2,3,\ldots\}} x_j^{\alpha_i} \\
&= \sum_{(j_1,j_2,\ldots,j_\ell)\in\{1,2,3,\ldots\}^\ell} \prod_{i=1}^{\ell} x_{j_i}^{\alpha_i} \qquad \text{(by the product rule)} \\
&= \underbrace{\sum_{\varphi\in\{1,2,3,\ldots\}^{[\ell]}}}_{=\sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}}} \underbrace{\prod_{i=1}^{\ell} x_{\varphi(i)}^{\alpha_i}}_{=x_{\varphi(1)}^{\alpha_1} x_{\varphi(2)}^{\alpha_2} \cdots x_{\varphi(\ell)}^{\alpha_\ell}} \\
&\qquad \left(\begin{array}{c}\text{here, we have substituted } (\varphi(1), \varphi(2), \ldots, \varphi(\ell)) \text{ for } (j_1, j_2, \ldots, j_\ell) \\ \text{in the sum, since the map (13.46.109) is a bijection}\end{array}\right) \\
&= \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} x_{\varphi(1)}^{\alpha_1} x_{\varphi(2)}^{\alpha_2} \cdots x_{\varphi(\ell)}^{\alpha_\ell}.
\end{aligned}$$

Comparing this with

$$\sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \underbrace{\mathbf{x}^{\varphi_*\alpha}}_{\substack{=x_{\varphi(1)}^{\alpha_1} x_{\varphi(2)}^{\alpha_2} \cdots x_{\varphi(\ell)}^{\alpha_\ell} \\ \text{(by Proposition 13.46.44 (applied to } p=\ell))}} = \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} x_{\varphi(1)}^{\alpha_1} x_{\varphi(2)}^{\alpha_2} \cdots x_{\varphi(\ell)}^{\alpha_\ell},$$

we obtain $p_{\alpha_1} p_{\alpha_2} \cdots p_{\alpha_\ell} = \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \mathbf{x}^{\varphi_*\alpha}$. This proves Proposition 13.46.46. □

Finally, let us state a proposition that follows immediately from the definition of a weak composition:

Proposition 13.46.47. *Let μ be a weak composition. Then, there exists a $q \in \mathbb{N}$ such that $\mu = (\mu_1, \mu_2, \ldots, \mu_q)$.* [564]

Now, let us resume the solution of Exercise 2.2.13.

(j) Let λ be a partition. Let μ be a weak composition. Let $\ell = \ell(\lambda)$. We must prove that the number $b_{\lambda,\mu}$ is well-defined. In other words, we must prove that there are only finitely many maps $\varphi : \{1, 2, \ldots, \ell\} \to \{1, 2, 3, \ldots\}$ satisfying $\left(\mu_j = \sum_{\substack{i\in\{1,2,\ldots,\ell\};\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1\right)$.

We have $\ell = \ell(\lambda)$; thus, $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$. Hence, λ is an ℓ-tuple in $\mathbb{N}^\ell$.

[564] Keep in mind that we are identifying any k-tuple $(a_1, a_2, \ldots, a_k) \in \mathbb{N}^k$ with the weak composition $(a_1, a_2, \ldots, a_k, 0, 0, 0, \ldots)$. Thus, the q-tuple $(\mu_1, \mu_2, \ldots, \mu_q)$ is identified with the weak composition $(\mu_1, \mu_2, \ldots, \mu_q, 0, 0, 0, \ldots)$.

We have $\ell = \ell(\lambda)$. Hence, the definition of $\mathfrak{B}'_{\lambda,\mu}$ yields

$$\mathfrak{B}'_{\lambda,\mu} = \left\{ \varphi : [\ell] \to \{1,2,3,\ldots\} \mid \underbrace{\mu_j = \sum_{\substack{i \in [\ell];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}}_{\substack{\iff \left(\mu_j = \sum_{\substack{i\in[\ell];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1\right) \\ \text{(since the } j \in \{1,2,3,\ldots\} \text{ are precisely the integers } j \geq 1\text{)}}} \right\}$$

$$= \left\{ \varphi : [\ell] \to \{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i \in [\ell];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1 \right\}$$

$$= \left\{ \varphi : \{1,2,\ldots,\ell\} \to \{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i \in \{1,2,\ldots,\ell\};\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1 \right\} \tag{13.46.110}$$

(since $[\ell] = \{1,2,\ldots,\ell\}$).

Proposition 13.46.47 shows that there exists some $q \in \mathbb{N}$ such that $\mu = (\mu_1, \mu_2, \ldots, \mu_q)$. Consider this q. Thus, μ is a q-tuple in $\mathbb{N}^q$ (since $\mu = (\mu_1, \mu_2, \ldots, \mu_q)$). Hence, the set $\mathfrak{B}_{\lambda,\mu,\ell,q}$ is well-defined (since $\lambda \in \mathbb{N}^\ell$ and $\mu \in \mathbb{N}^q$). Also, $\mu \in \mathrm{WC}$ (since μ is a weak composition). Thus, Proposition 13.46.39 (applied to $p = \ell$) shows that $\mathfrak{B}'_{\lambda,\mu} \cong \mathfrak{B}_{\lambda,\mu,\ell,q}$ as sets. But the definition of $\mathfrak{B}_{\lambda,\mu,\ell,q}$ yields

$$\mathfrak{B}_{\lambda,\mu,\ell,q} = \{\varphi : [\ell] \to [q] \mid \mu = \varphi_* \lambda\} \subset \{\varphi : [\ell] \to [q]\} = [q]^{[\ell]}.$$

Hence, $\mathfrak{B}_{\lambda,\mu,\ell,q}$ is a finite set (since $[q]^{[\ell]}$ is a finite set). Therefore, the set $\mathfrak{B}'_{\lambda,\mu}$ is a finite set as well (since $\mathfrak{B}'_{\lambda,\mu} \cong \mathfrak{B}_{\lambda,\mu,\ell,q}$ as sets). In view of (13.46.110), this rewrites as follows: The set

$$\left\{ \varphi : \{1,2,\ldots,\ell\} \to \{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i \in \{1,2,\ldots,\ell\};\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1 \right\}$$

is a finite set. In other words, there are only finitely many maps $\varphi : \{1,2,\ldots,\ell\} \to \{1,2,3,\ldots\}$ satisfying $\left(\mu_j = \sum_{\substack{i \in \{1,2,\ldots,\ell\};\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1 \right)$. This solves Exercise 2.2.13(j).

(k) Let $\lambda \in \mathrm{Par}_n$. Let $\ell = \ell(\lambda)$. Thus, $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ (by the definition of $\ell(\lambda)$). Thus, $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell) \in \mathbb{N}^\ell$. Therefore, for every map $\varphi : [\ell] \to \{1,2,3,\ldots\}$, a weak composition $\varphi_* \lambda \in \mathrm{WC}$ is defined (according to Definition 13.46.43, applied to $p = \ell$, $\alpha = \lambda$ and $\alpha_i = \lambda_i$). The definition of this weak composition $\varphi_* \lambda$ yields

$$\varphi_* \lambda = \left(\sum_{i \in \varphi^{-1}\{1\}} \lambda_i, \sum_{i \in \varphi^{-1}\{2\}} \lambda_i, \sum_{i \in \varphi^{-1}\{3\}} \lambda_i, \ldots \right) \tag{13.46.111}$$

for any map $\varphi : [\ell] \to \{1, 2, 3, \ldots\}$. Hence, for each map $\varphi : [\ell] \to \{1, 2, 3, \ldots\}$, we have the following chain of logical equivalences:

$$\begin{aligned}
&\left(\underbrace{\mu}_{=(\mu_1,\mu_2,\mu_3,\ldots)} = \underbrace{\varphi_*\lambda}_{\substack{=\left(\sum_{i\in\varphi^{-1}\{1\}}\lambda_i,\sum_{i\in\varphi^{-1}\{2\}}\lambda_i,\sum_{i\in\varphi^{-1}\{3\}}\lambda_i,\ldots\right) \\ \text{(by (13.46.111))}}} \right) \\
\Longleftrightarrow\ &\left((\mu_1, \mu_2, \mu_3, \ldots) = \left(\sum_{i\in\varphi^{-1}\{1\}} \lambda_i, \sum_{i\in\varphi^{-1}\{2\}} \lambda_i, \sum_{i\in\varphi^{-1}\{3\}} \lambda_i, \ldots \right) \right) \\
\Longleftrightarrow\ &\left(\mu_j = \underbrace{\sum_{i\in\varphi^{-1}\{j\}}}_{=\sum_{\substack{i\in[\ell];\\ \varphi(i)=j}}} \lambda_i \text{ for all } j \geq 1 \right) \\
\Longleftrightarrow\ &\left(\mu_j = \sum_{\substack{i\in[\ell];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1 \right).
\end{aligned}$$

Thus,

$$\begin{aligned}
&\{\varphi : [\ell] \to \{1, 2, 3, \ldots\} \mid \mu = \varphi_*\lambda\} \\
&= \left\{ \varphi : [\ell] \to \{1, 2, 3, \ldots\} \mid \mu_j = \sum_{\substack{i\in[\ell];\\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1 \right\}. \qquad (13.46.112)
\end{aligned}$$

We have $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ with $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_\ell > 0$ (since $\ell = \ell(\lambda)$). Hence, $p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell}$ (by the definition of p_λ).

From $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_\ell > 0$, we also obtain ($\lambda_i > 0$ for each $i \in [\ell]$). Hence, Proposition 13.46.46 (applied to $\alpha = \lambda$ and $\alpha_i = \lambda_i$) yields

$$p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell} = \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \mathbf{x}^{\varphi_*\lambda}$$

in $\mathbf{k}[[\mathbf{x}]]$.

Now, let $\mu \in \operatorname{Par}_n$. Thus, $\mu \in \operatorname{Par}_n \subset \operatorname{Par} \subset \operatorname{WC}$. From $p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell} = \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \mathbf{x}^{\varphi_* \lambda}$, we obtain

$$\begin{aligned}
&\left[\mathbf{x}^{\mu}\right]\left(p_\lambda\right) \\
&= \left[\mathbf{x}^{\mu}\right]\left(\sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \mathbf{x}^{\varphi_*\lambda}\right) = \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \underbrace{\left[\mathbf{x}^{\mu}\right]\left(\mathbf{x}^{\varphi_*\lambda}\right)}_{\substack{=\delta_{\mu,\varphi_*\lambda} \\ \text{(by (13.46.1) (applied to } \alpha=\varphi_*\lambda))}} \\
&= \sum_{\varphi:[\ell]\to\{1,2,3,\ldots\}} \delta_{\mu,\varphi_*\lambda} \\
&= \sum_{\substack{\varphi:[\ell]\to\{1,2,3,\ldots\}; \\ \mu=\varphi_*\lambda}} \underbrace{\delta_{\mu,\varphi_*\lambda}}_{\substack{=1 \\ \text{(since } \mu=\varphi_*\lambda)}} + \sum_{\substack{\varphi:[\ell]\to\{1,2,3,\ldots\}; \\ \mu\neq\varphi_*\lambda}} \underbrace{\delta_{\mu,\varphi_*\lambda}}_{\substack{=0 \\ \text{(since } \mu\neq\varphi_*\lambda)}} \\
&= \sum_{\substack{\varphi:[\ell]\to\{1,2,3,\ldots\}; \\ \mu=\varphi_*\lambda}} 1 + \underbrace{\sum_{\substack{\varphi:[\ell]\to\{1,2,3,\ldots\}; \\ \mu\neq\varphi_*\lambda}} 0}_{=0} = \sum_{\substack{\varphi:[\ell]\to\{1,2,3,\ldots\}; \\ \mu=\varphi_*\lambda}} 1 \\
&= \left|\left\{\varphi:[\ell]\to\{1,2,3,\ldots\} \mid \mu=\varphi_*\lambda\right\}\right| \cdot 1 \\
&= \left|\left\{\varphi:[\ell]\to\{1,2,3,\ldots\} \mid \mu=\varphi_*\lambda\right\}\right| \\
&= \left|\left\{\varphi:[\ell]\to\{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i\in[\ell]; \\ \varphi(i)=j}} \lambda_i \text{ for all } j\geq 1\right\}\right| \qquad (13.46.113)
\end{aligned}$$

(by (13.46.112)).

On the other hand, the definition of $b_{\lambda,\mu}$ shows that $b_{\lambda,\mu}$ is the number of all maps $\varphi : \{1,2,\ldots,\ell\} \to \{1,2,3,\ldots\}$ satisfying $\left(\mu_j = \sum_{\substack{i\in\{1,2,\ldots,\ell\}; \\ \varphi(i)=j}} \lambda_i \text{ for all } j\geq 1\right)$ (since $\ell = \ell(\lambda)$). In light of $\{1,2,\ldots,\ell\} = [\ell]$, this rewrites as follows: $b_{\lambda,\mu}$ is the number of all maps $\varphi : [\ell] \to \{1,2,3,\ldots\}$ satisfying $\left(\mu_j = \sum_{\substack{i\in[\ell]; \\ \varphi(i)=j}} \lambda_i \text{ for all } j\geq 1\right)$. In other words,

$$b_{\lambda,\mu} = \left|\left\{\varphi:[\ell]\to\{1,2,3,\ldots\} \mid \mu_j = \sum_{\substack{i\in[\ell]; \\ \varphi(i)=j}} \lambda_i \text{ for all } j\geq 1\right\}\right|.$$

Comparing this with (13.46.113), we obtain

$$\left[\mathbf{x}^{\mu}\right]\left(p_\lambda\right) = b_{\lambda,\mu}. \qquad (13.46.114)$$

Now, forget that we fixed μ. We thus have proven the equality (13.46.114) for every $\mu \in \operatorname{Par}_n$.

But $\lambda \in \operatorname{Par}_n$, so that $|\lambda| = n$. Hence, $n = \left|\underbrace{\lambda}_{=(\lambda_1,\lambda_2,\ldots,\lambda_\ell)}\right| = |(\lambda_1,\lambda_2,\ldots,\lambda_\ell)| = \lambda_1+\lambda_2+\cdots+\lambda_\ell$.

Let $i \in \{1,2,\ldots,\ell\}$. Then, p_{λ_i} is a homogeneous element of Λ having degree λ_i (because for each positive integer m, the element p_m is a homogeneous element of Λ having degree m).

Now, forget that we fixed i. We thus have shown that for each $i \in \{1,2,\ldots,\ell\}$, the element p_{λ_i} is a homogeneous element of Λ having degree λ_i. In other words, $p_{\lambda_1}, p_{\lambda_2}, \ldots, p_{\lambda_\ell}$ are homogeneous elements of Λ having degrees $\lambda_1, \lambda_2, \ldots, \lambda_\ell$, respectively. Hence, the product $p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell}$ of these elements is a homogeneous element of Λ having degree $\lambda_1+\lambda_2+\cdots+\lambda_\ell$. In light of $p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell}$ and $n =$

$\lambda_1 + \lambda_2 + \cdots + \lambda_\ell$, this rewrites as follows: The element p_λ is a homogeneous element of Λ having degree n. In other words, $p_\lambda \in \Lambda_n$. Thus, Exercise 2.2.13(a) (applied to $f = p_\lambda$) yields

$$p_\lambda = \sum_{\mu \in \operatorname{Par}_n} \underbrace{\left(\left[\mathbf{x}^\mu\right]\left(p_\lambda\right)\right)}_{\substack{= b_{\lambda,\mu} \\ \text{(by (13.46.114))}}} m_\mu = \sum_{\mu \in \operatorname{Par}_n} b_{\lambda,\mu} m_\mu .$$

This solves Exercise 2.2.13(k).

Before we come to the solution of Exercise 2.2.13(l), let us state a simple lemma:

Lemma 13.46.48. *Let λ be a partition. Let μ be a weak composition. Then:*

(a) *We have $b_{\lambda,\mu} = \left|\mathfrak{B}'_{\lambda,\mu}\right|$.*

(b) *Let $p = \ell(\lambda)$. Let $q \in \mathbb{N}$ be such that $\mu = (\mu_1, \mu_2, \ldots, \mu_q)$ (that is, $\mu_i = 0$ for all integers $i > q$). Then, the set $\mathfrak{B}_{\lambda,\mu,p,q}$ is well-defined and satisfies $b_{\lambda,\mu} = \left|\mathfrak{B}_{\lambda,\mu,p,q}\right|$.*

Proof of Lemma 13.46.48. We know that λ is a partition.

We have $p = \ell(\lambda)$. Hence, the definition of $\mathfrak{B}'_{\lambda,\mu}$ yields

$$\mathfrak{B}'_{\lambda,\mu} = \left\{ \varphi : [p] \to \{1,2,3,\ldots\} \ \mid \ \underbrace{\mu_j = \sum_{\substack{i \in [p]; \\ \varphi(i) = j}} \lambda_i \text{ for all } j \in \{1,2,3,\ldots\}}_{\substack{\Longleftrightarrow \left(\mu_j = \sum_{\substack{i \in [p]; \\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1\right) \\ \text{(since the } j \in \{1,2,3,\ldots\} \text{ are precisely the integers } j \geq 1\text{)}}} \right\}$$

$$= \left\{ \varphi : [p] \to \{1,2,3,\ldots\} \ \mid \ \mu_j = \sum_{\substack{i \in [p]; \\ \varphi(i) = j}} \lambda_i \text{ for all } j \geq 1 \right\}. \tag{13.46.115}$$

On the other hand, the definition of $b_{\lambda,\mu}$ shows that $b_{\lambda,\mu}$ is the number of all maps $\varphi : \{1,2,\ldots,p\} \to \{1,2,3,\ldots\}$ satisfying $\left(\mu_j = \sum_{\substack{i \in \{1,2,\ldots,p\}; \\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1\right)$ (since $p = p(\lambda)$). In view of $\{1,2,\ldots,p\} = [p]$, this rewrites as follows: $b_{\lambda,\mu}$ is the number of all maps $\varphi : [p] \to \{1,2,3,\ldots\}$ satisfying $\left(\mu_j = \sum_{\substack{i \in [p]; \\ \varphi(i)=j}} \lambda_i \text{ for all } j \geq 1\right)$.

In other words,

$$b_{\lambda,\mu} = \left| \underbrace{\left\{ \varphi : [p] \to \{1,2,3,\ldots\} \ \mid \ \mu_j = \sum_{\substack{i \in [p]; \\ \varphi(i) = j}} \lambda_i \text{ for all } j \geq 1 \right\}}_{\substack{= \mathfrak{B}'_{\lambda,\mu} \\ \text{(by (13.46.115))}}} \right| = \left|\mathfrak{B}'_{\lambda,\mu}\right| .$$

This proves Lemma 13.46.48(a).

(b) From $p = \ell(\lambda)$, we obtain $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p)$; thus, λ is a p-tuple in $\mathbb{N}^p$. Also, $\mu = (\mu_1, \mu_2, \ldots, \mu_q) \in \mathbb{N}^q$. Thus, μ is a q-tuple in $\mathbb{N}^q$. Hence, the set $\mathfrak{B}_{\lambda,\mu,p,q}$ is well-defined (since $\lambda \in \mathbb{N}^p$ and $\mu \in \mathbb{N}^q$). Proposition 13.46.39 yields that $\mathfrak{B}'_{\lambda,\mu} \cong \mathfrak{B}_{\lambda,\mu,p,q}$ as sets. But Lemma 13.46.48(a) shows that $b_{\lambda,\mu} = \left|\mathfrak{B}'_{\lambda,\mu}\right| = |\mathfrak{B}_{\lambda,\mu,p,q}|$ (since $\mathfrak{B}'_{\lambda,\mu} \cong \mathfrak{B}_{\lambda,\mu,p,q}$ as sets). Thus, Lemma 13.46.48(b) is proven. □

We now resume the solution of Exercise 2.2.13.

(l) Let $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$ be any partitions that don't satisfy $\mu \triangleright \lambda$. We must prove that $b_{\lambda,\mu} = 0$.

Indeed, assume the contrary. Thus, $b_{\lambda,\mu} \neq 0$. But Lemma 13.46.48(a) yields $b_{\lambda,\mu} = \left|\mathfrak{B}'_{\lambda,\mu}\right|$ (since μ is a weak composition (since μ is a partition)). Hence, $\left|\mathfrak{B}'_{\lambda,\mu}\right| = b_{\lambda,\mu} \neq 0$. In other words, $\mathfrak{B}'_{\lambda,\mu} \neq \varnothing$. Thus, Proposition 13.46.40 shows that $\mu \triangleright \lambda$. This contradicts the fact that we don't have $\mu \triangleright \lambda$.

This contradiction proves that our assumption was wrong. Hence, $b_{\lambda,\mu} = 0$ is proven. This solves Exercise 2.2.13(l).

(m) Let $\lambda \in \operatorname{Par}_n$. We must prove that $b_{\lambda,\lambda}$ is a positive integer.

Let $k = \ell(\lambda)$. Thus, $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_k)$ (by the definition of $\ell(\lambda)$). Clearly, λ is a weak composition (since λ is a partition). Hence, Lemma 13.46.48(b) (applied to $\mu = \lambda$, $p = k$ and $q = k$) shows that the set $\mathfrak{B}_{\lambda,\lambda,k,k}$ is well-defined and satisfies $b_{\lambda,\lambda} = |\mathfrak{B}_{\lambda,\lambda,k,k}|$. But $\lambda \in \operatorname{Par}_n \subset \operatorname{Par}$. Hence, Proposition 13.46.41(b) (applied to $\mu = \lambda$) shows that $\mathfrak{B}_{\lambda,\lambda,k,k}$ is a subgroup of $\mathfrak{S}_k$. Thus, the set $\mathfrak{B}_{\lambda,\lambda,k,k}$ contains the neutral element of $\mathfrak{S}_k$. Thus, the set $\mathfrak{B}_{\lambda,\lambda,k,k}$ contains at least one element, and therefore is nonempty. Thus, $|\mathfrak{B}_{\lambda,\lambda,k,k}| > 0$.

Hence, $b_{\lambda,\lambda} = |\mathfrak{B}_{\lambda,\lambda,k,k}| > 0$. Since $b_{\lambda,\lambda}$ is an integer, we can therefore conclude that $b_{\lambda,\lambda}$ is a positive integer. This solves Exercise 2.2.13(m).

(n) Let $\mu = (\mu_1, \mu_2, \ldots, \mu_k) \in \operatorname{Par}_n$ be a partition. Let $k = \ell(\mu)$. We must show that the integer $b_{\mu,\mu}$ is the size of the subgroup of $\mathfrak{S}_k$ consisting of all permutations $\sigma \in \mathfrak{S}_k$ having each i satisfy $\mu_{\sigma(i)} = \mu_i$. In particular, we must show that this subgroup is indeed a subgroup.

Clearly, μ is a weak composition (since μ is a partition). Hence, Lemma 13.46.48(b) (applied to $\lambda = \mu$, $p = k$ and $q = k$) shows that the set $\mathfrak{B}_{\mu,\mu,k,k}$ is well-defined and satisfies $b_{\mu,\mu} = |\mathfrak{B}_{\mu,\mu,k,k}|$.

We have $\mu \in \operatorname{Par}_n \subset \operatorname{Par}$. Hence, Proposition 13.46.41(a) shows that

$$\mathfrak{B}_{\mu,\mu,k,k} = \left\{\sigma \in \mathfrak{S}_k \ \mid \ \mu_{\sigma(i)} = \mu_i \text{ for each } i \in [k]\right\}. \tag{13.46.116}$$

Furthermore, Proposition 13.46.41(b) shows that $\mathfrak{B}_{\mu,\mu,k,k}$ is a subgroup of $\mathfrak{S}_k$.

Now,

$$\begin{aligned}
&\left(\text{the set of all permutations } \sigma \in \mathfrak{S}_k \text{ having each } i \text{ satisfy } \mu_{\sigma(i)} = \mu_i\right) \\
&= \left\{\sigma \in \mathfrak{S}_k \ \mid \ \text{each } i \text{ satisfies } \mu_{\sigma(i)} = \mu_i\right\} \\
&= \left\{\sigma \in \mathfrak{S}_k \ \mid \ \text{each } i \in \underbrace{\{1, 2, \ldots, k\}}_{=[k]} \text{ satisfies } \mu_{\sigma(i)} = \mu_i\right\} \\
&= \left\{\sigma \in \mathfrak{S}_k \ \mid \ \text{each } i \in [k] \text{ satisfies } \mu_{\sigma(i)} = \mu_i\right\} \\
&= \left\{\sigma \in \mathfrak{S}_k \ \mid \ \mu_{\sigma(i)} = \mu_i \text{ for each } i \in [k]\right\} \\
&= \mathfrak{B}_{\mu,\mu,k,k} \qquad (\text{by } (13.46.116)).
\end{aligned} \tag{13.46.117}$$

But recall that $\mathfrak{B}_{\mu,\mu,k,k}$ is a subgroup of $\mathfrak{S}_k$. In view of (13.46.117), this rewrites as follows: The set of all permutations $\sigma \in \mathfrak{S}_k$ having each i satisfy $\mu_{\sigma(i)} = \mu_i$ is a subgroup of $\mathfrak{S}_k$. This subgroup thus is the subgroup of $\mathfrak{S}_k$ consisting of all permutations $\sigma \in \mathfrak{S}_k$ having each i satisfy $\mu_{\sigma(i)} = \mu_i$. The size of this subgroup is clearly

$$\left|\underbrace{\left\{\sigma \in \mathfrak{S}_k \ \mid \ \text{each } i \text{ satisfies } \mu_{\sigma(i)} = \mu_i\right\}}_{=\mathfrak{B}_{\mu,\mu,k,k}}\right| = |\mathfrak{B}_{\mu,\mu,k,k}| = b_{\mu,\mu} \qquad (\text{since } b_{\mu,\mu} = |\mathfrak{B}_{\mu,\mu,k,k}|).$$

Thus, $b_{\mu,\mu}$ is the size of the subgroup of $\mathfrak{S}_k$ consisting of all permutations $\sigma \in \mathfrak{S}_k$ having each i satisfy $\mu_{\sigma(i)} = \mu_i$. (In particular, we have shown that this subgroup is indeed a subgroup.) This solves Exercise 2.2.13(n).

Before we come to the solution of Exercise 2.2.13(o), let us prove some further auxiliary results.

Proposition 13.46.49. *Let $\mu \in \operatorname{Par}$. Let $k = \ell(\mu)$. Proposition 13.46.41(b) shows that the set $\mathfrak{B}_{\mu,\mu,k,k}$ is a subgroup of $\mathfrak{S}_k$. Thus, $\mathfrak{B}_{\mu,\mu,k,k}$ is a group.*

Let $p \in \mathbb{N}$. Let $\lambda \in \mathbb{N}^p$. Then, the set $\mathfrak{B}_{\lambda,\mu,p,k}$ can be made into a left $\mathfrak{B}_{\mu,\mu,k,k}$-set (i.e., it can be equipped with an action of the group $\mathfrak{B}_{\mu,\mu,k,k}$ from the left) in such a way that the group $\mathfrak{B}_{\mu,\mu,k,k}$ acts freely on $\mathfrak{B}_{\lambda,\mu,p,k}$.

Proof of Proposition 13.46.49. For any $\alpha \in \mathfrak{B}_{\mu,\mu,k,k}$ and $\beta \in \mathfrak{B}_{\lambda,\mu,p,k}$, we have $\alpha \circ \beta \in \mathfrak{B}_{\lambda,\mu,p,k}$ [565]. Thus, we can try to define an action of the group $\mathfrak{B}_{\mu,\mu,k,k}$ on the set $\mathfrak{B}_{\lambda,\mu,p,k}$ from the left by setting

$$(\alpha\beta = \alpha \circ \beta \qquad \text{for all } \alpha \in \mathfrak{B}_{\mu,\mu,k,k} \text{ and } \beta \in \mathfrak{B}_{\lambda,\mu,p,k}). \tag{13.46.118}$$

In order to show that this definition actually defines an action of the group $\mathfrak{B}_{\mu,\mu,k,k}$ on the set $\mathfrak{B}_{\lambda,\mu,p,k}$, we need to prove the following two observations:

Observation 1: We have $\operatorname{id}_{\{1,2,\ldots,k\}} \circ \gamma = \gamma$ for all $\gamma \in \mathfrak{B}_{\lambda,\mu,p,k}$.

Observation 2: We have $(\alpha \circ \beta) \circ \gamma = \alpha \circ (\beta \circ \gamma)$ for all $\alpha \in \mathfrak{B}_{\mu,\mu,k,k}$, $\beta \in \mathfrak{B}_{\mu,\mu,k,k}$ and $\gamma \in \mathfrak{B}_{\lambda,\mu,p,k}$.

However, both Observation 1 and Observation 2 are obvious. Thus, we have shown that (13.46.118) actually defines an action of the group $\mathfrak{B}_{\mu,\mu,k,k}$ on the set $\mathfrak{B}_{\lambda,\mu,p,k}$. Consider this action. Thus, the set $\mathfrak{B}_{\lambda,\mu,p,k}$ has been made into a left $\mathfrak{B}_{\mu,\mu,k,k}$-set.

We shall now prove that the group $\mathfrak{B}_{\mu,\mu,k,k}$ acts freely on $\mathfrak{B}_{\lambda,\mu,p,k}$. In order to do so, we must prove the following observation:

Observation 3: If $\alpha \in \mathfrak{B}_{\mu,\mu,k,k}$, $\beta \in \mathfrak{B}_{\mu,\mu,k,k}$ and $\gamma \in \mathfrak{B}_{\lambda,\mu,p,k}$ are such that $\alpha \circ \gamma = \beta \circ \gamma$, then $\alpha = \beta$.

[*Proof of Observation 3:* Let $\alpha \in \mathfrak{B}_{\mu,\mu,k,k}$, $\beta \in \mathfrak{B}_{\mu,\mu,k,k}$ and $\gamma \in \mathfrak{B}_{\lambda,\mu,p,k}$ be such that $\alpha \circ \gamma = \beta \circ \gamma$. We must prove that $\alpha = \beta$.

We have $\alpha \in \mathfrak{B}_{\mu,\mu,k,k} = \{\varphi : [k] \to [k] \mid \mu = \varphi_* \mu\}$ (by the definition of $\mathfrak{B}_{\mu,\mu,k,k}$). In other words, α is a map $[k] \to [k]$ and satisfies $\mu = \alpha_* \mu$. The same argument (applied to β instead of α) shows that β is a map $[k] \to [k]$ and satisfies $\mu = \beta_* \mu$.

We have $\gamma \in \mathfrak{B}_{\lambda,\mu,p,k} = \{\varphi : [p] \to [k] \mid \mu = \varphi_* \lambda\}$ (by the definition of $\mathfrak{B}_{\lambda,\mu,p,k}$). In other words, γ is a map $[p] \to [k]$ and satisfies $\mu = \gamma_* \lambda$.

Write the p-tuple λ in the form $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p)$.

Also, $\ell(\mu) = k$. Hence, $\mu = (\mu_1, \mu_2, \ldots, \mu_k) \in \mathbb{N}^k$ and $\mu_1 \geq \mu_2 \geq \cdots \geq \mu_k > 0$. From $\mu_1 \geq \mu_2 \geq \cdots \geq \mu_k > 0$, we obtain ($\mu_i > 0$ for each $i \in [k]$). Hence, Lemma 13.46.31 (applied to $q = k$, $\varphi = \gamma$, $\alpha = \lambda$, $\alpha_i = \lambda_i$, $\beta = \mu$ and $\beta_i = \mu_i$) shows that the map γ is surjective. Hence, we can cancel γ from the equality $\alpha \circ \gamma = \beta \circ \gamma$. Thus, we obtain $\alpha = \beta$. This proves Observation 3.]

Observation 3 shows that the group $\mathfrak{B}_{\mu,\mu,k,k}$ acts freely on $\mathfrak{B}_{\lambda,\mu,p,k}$ (by the definition of "acting freely"). Thus, the set $\mathfrak{B}_{\lambda,\mu,p,k}$ can be made into a left $\mathfrak{B}_{\mu,\mu,k,k}$-set in such a way that the group $\mathfrak{B}_{\mu,\mu,k,k}$ acts freely on $\mathfrak{B}_{\lambda,\mu,p,k}$ (namely, by using the above-defined left action of $\mathfrak{B}_{\mu,\mu,k,k}$ on $\mathfrak{B}_{\lambda,\mu,p,k}$). This proves Proposition 13.46.49. □

Let us now recall a basic fact from abstract algebra:

Proposition 13.46.50. *Let G be a finite group. Let X be a finite left G-set. Assume that G acts freely on X. Then, $|G| \mid |X|$.*

[565] *Proof.* Let $\alpha \in \mathfrak{B}_{\mu,\mu,k,k}$ and $\beta \in \mathfrak{B}_{\lambda,\mu,p,k}$. We must show that $\alpha \circ \beta \in \mathfrak{B}_{\lambda,\mu,p,k}$.

We have $\alpha \in \mathfrak{B}_{\mu,\mu,k,k} = \{\varphi : [k] \to [k] \mid \mu = \varphi_* \mu\}$ (by the definition of $\mathfrak{B}_{\mu,\mu,k,k}$). In other words, α is a map $[k] \to [k]$ and satisfies $\mu = \alpha_* \mu$.

We have $\beta \in \mathfrak{B}_{\lambda,\mu,p,k} = \{\varphi : [p] \to [k] \mid \mu = \varphi_* \lambda\}$ (by the definition of $\mathfrak{B}_{\lambda,\mu,p,k}$). In other words, β is a map $[p] \to [k]$ and satisfies $\mu = \beta_* \lambda$.

Now, Proposition 13.46.28 (applied to k, k, β, α and λ instead of q, r, φ, ψ and α) yields $(\alpha \circ \beta)_* \lambda = \alpha_* \left(\underbrace{\beta_* \lambda}_{=\mu} \right) = \alpha_* \mu = \mu$. In other words, $\mu = (\alpha \circ \beta)_* \lambda$. Hence, $\alpha \circ \beta$ is a map $[p] \to [k]$ (since α is a map $[k] \to [k]$, and since β is a map $[p] \to [k]$), and satisfies $\mu = (\alpha \circ \beta)_* \lambda$. In other words, $\alpha \circ \beta \in \{\varphi : [p] \to [k] \mid \mu = \varphi_* \lambda\}$. This rewrites as $\alpha \circ \beta \in \mathfrak{B}_{\lambda,\mu,p,k}$ (since $\mathfrak{B}_{\lambda,\mu,p,k} = \{\varphi : [p] \to [k] \mid \mu = \varphi_* \lambda\}$). Qed.

Proof of Proposition 13.46.50. This fact is well-known, so let us merely sketch the proof: The G-set X is a disjoint union of orbits (since every G-set is a disjoint union of orbits). Thus, the G-set X is a disjoint union of finitely many orbits (since X is finite). In other words, we have $X = O_1 \cup O_2 \cup \cdots \cup O_k$ for some list $(O_1, O_2, \ldots, O_k)$ of disjoint orbits of G on X. Consider this list $(O_1, O_2, \ldots, O_k)$.

Every $i \in \{1, 2, \ldots, k\}$ satisfies $|O_i| = |G|$ [566]. Hence, $\sum_{i=1}^k \underbrace{|O_i|}_{=|G|} = \sum_{i=1}^k |G| = k\,|G|$.

From $X = O_1 \cup O_2 \cup \cdots \cup O_k$, we obtain

$$|X| = |O_1 \cup O_2 \cup \cdots \cup O_k| = |O_1| + |O_2| + \cdots + |O_k| \qquad \text{(since the orbits } O_1, O_2, \ldots, O_k \text{ are disjoint)}$$
$$= \sum_{i=1}^{k} |O_i| = k\,|G|\,.$$

Thus, $|G| \mid k\,|G| = |X|$. This proves Proposition 13.46.50. □

We now resume the solution of Exercise 2.2.13.

(o) Let $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$. We must prove that $b_{\mu,\mu} \mid b_{\lambda,\mu}$.

Let $p = \ell(\lambda)$. Thus, $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p)$ (by the definition of $\ell(\lambda)$). Hence, $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_p) \in \mathbb{N}^p$.

We have $\mu \in \operatorname{Par}_n \subset \operatorname{Par}$. Let $k = \ell(\mu)$. Proposition 13.46.41(b) shows that the set $\mathfrak{B}_{\mu,\mu,k,k}$ is a subgroup of $\mathfrak{S}_k$. Thus, $\mathfrak{B}_{\mu,\mu,k,k}$ is a finite group (since $\mathfrak{S}_k$ is a finite group).

But λ is a partition (since $\lambda \in \operatorname{Par}_n \subset \operatorname{Par}$). Also, μ is a partition (since $\mu \in \operatorname{Par}$), thus a weak composition. Furthermore, $k = \ell(\mu)$; thus, $\mu = (\mu_1, \mu_2, \ldots, \mu_k)$ (by the definition of $\ell(\mu)$). Hence, Lemma 13.46.48(b) (applied to $q = k$) shows that the set $\mathfrak{B}_{\lambda,\mu,p,k}$ is well-defined and satisfies $b_{\lambda,\mu} = |\mathfrak{B}_{\lambda,\mu,p,k}|$.

Furthermore, Lemma 13.46.48(b) (applied to k, k and μ instead of p, q and λ) shows that the set $\mathfrak{B}_{\mu,\mu,k,k}$ is well-defined and satisfies $b_{\mu,\mu} = |\mathfrak{B}_{\mu,\mu,k,k}|$.

The definition of $\mathfrak{B}_{\lambda,\mu,p,k}$ yields $\mathfrak{B}_{\lambda,\mu,p,k} = \{\varphi : [p] \to [k] \mid \mu = \varphi_* \lambda\} \subset \{\varphi : [p] \to [k]\} = [k]^{[p]}$. Thus, $\mathfrak{B}_{\lambda,\mu,p,k}$ is a finite set (since $[k]^{[p]}$ is a finite set).

Proposition 13.46.49 shows that the set $\mathfrak{B}_{\lambda,\mu,p,k}$ can be made into a left $\mathfrak{B}_{\mu,\mu,k,k}$-set (i.e., it can be equipped with an action of the group $\mathfrak{B}_{\mu,\mu,k,k}$ from the left) in such a way that the group $\mathfrak{B}_{\mu,\mu,k,k}$ acts freely on $\mathfrak{B}_{\lambda,\mu,p,k}$. Consider this action. Proposition 13.46.50 (applied to $G = \mathfrak{B}_{\mu,\mu,k,k}$ and $X = \mathfrak{B}_{\lambda,\mu,p,k}$) now yields $|\mathfrak{B}_{\mu,\mu,k,k}| \mid |\mathfrak{B}_{\lambda,\mu,p,k}|$. Thus, $b_{\mu,\mu} = |\mathfrak{B}_{\mu,\mu,k,k}| \mid |\mathfrak{B}_{\lambda,\mu,p,k}| = b_{\lambda,\mu}$ (since $b_{\lambda,\mu} = |\mathfrak{B}_{\lambda,\mu,p,k}|$). This solves Exercise 2.2.13(o).

13.47. **Solution to Exercise 2.2.14.**

Solution to Exercise 2.2.14. Let us first consider the polynomial ring $\mathbf{k}[x_1, x_2, x_3, \ldots]$ in countably many indeterminates $x_1, x_2, x_3, \ldots$.

Let $f : \mathbf{k}[x_1, x_2, x_3, \ldots] \to A$ be the $\mathbf{k}$-algebra homomorphism that sends $x_1, x_2, x_3, \ldots$ to $v_1, v_2, v_3, \ldots$, respectively. This is well-defined by the universal property of the polynomial ring $\mathbf{k}[x_1, x_2, x_3, \ldots]$ (since A is commutative). The $\mathbf{k}$-algebra homomorphism f is an instance of an evaluation homomorphism; it sends each polynomial $P \in \mathbf{k}[x_1, x_2, x_3, \ldots]$ to $P(v_1, v_2, v_3, \ldots) \in A$. In other words,

$$f(P) = P(v_1, v_2, v_3, \ldots) \qquad \text{for each } P \in \mathbf{k}[x_1, x_2, x_3, \ldots]\,. \tag{13.47.1}$$

The map f is a $\mathbf{k}$-algebra homomorphism, and thus is $\mathbf{k}$-linear.

For each partition $\lambda \in \operatorname{Par}$, we define a monomial $\mathbf{x}_\lambda \in \mathbf{k}[x_1, x_2, x_3, \ldots]$ by

$$\mathbf{x}_\lambda = x_{\lambda_1} x_{\lambda_2} \cdots x_{\lambda_{\ell(\lambda)}}.$$

(This is well-defined, since $\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}$ are positive integers whenever $\lambda \in \operatorname{Par}$.)

If λ is a partition and i is a positive integer, then $m_i(\lambda)$ shall denote the multiplicity of i in λ (that is, the number of parts of λ equal to i).

Let WC denote the set of all weak compositions.

[566] *Proof.* Let $i \in \{1, 2, \ldots, k\}$. Thus, O_i is an orbit of G on X. In other words, $O_i = Gy$ for some $y \in X$. Consider this y.

The elements gy for $g \in G$ are all distinct (because if $gy = hy$ for two elements $g, h \in G$, then we must have $g = h$ (because G acts freely on X)). Thus, the number of these elements is precisely $|G|$. In other words, $|\{gy \mid g \in G\}| = |G|$. In view of $\{gy \mid g \in G\} = Gy = O_i$, this rewrites as $|O_i| = |G|$. Qed.

Every partition λ can be uniquely written in the form $\lambda = (1^{m_1} 2^{m_2} 3^{m_3} \cdots)$ for some weak composition $(m_1, m_2, m_3, \ldots)$. Thus, the map

$$\begin{aligned} \mathbf{part} : \mathrm{WC} &\to \mathrm{Par}, \\ (m_1, m_2, m_3, \ldots) &\mapsto (1^{m_1} 2^{m_2} 3^{m_3} \cdots) \end{aligned}$$

is a bijection. The inverse of this bijection is the map

$$\begin{aligned} \mathbf{mults} : \mathrm{Par} &\to \mathrm{WC}, \\ \lambda &\mapsto (m_1(\lambda), m_2(\lambda), m_3(\lambda), \ldots). \end{aligned}$$

Thus, this map **mults** is a bijection, too (since it is the inverse of a bijection).

It is easy to see that

$$\mathbf{x}_\lambda = \mathbf{x}^{\mathbf{mults}(\lambda)} \qquad \text{for any } \lambda \in \mathrm{Par} \tag{13.47.2}$$

[567]. In other words, $(\mathbf{x}_\lambda)_{\lambda \in \mathrm{Par}} = \left(\mathbf{x}^{\mathbf{mults}(\lambda)}\right)_{\lambda \in \mathrm{Par}}$.

The monomials in $\mathbf{k}[x_1, x_2, x_3, \ldots]$ have the form $\mathbf{x}^\alpha$ for $\alpha \in \mathrm{WC}$. It is well-known that these monomials form a basis of the $\mathbf{k}$-module $\mathbf{k}[x_1, x_2, x_3, \ldots]$ (since any polynomial ring has a basis consisting of the monomials). In other words, the family $(\mathbf{x}^\alpha)_{\alpha \in \mathrm{WC}}$ is a basis of the $\mathbf{k}$-module $\mathbf{k}[x_1, x_2, x_3, \ldots]$. The family $\left(\mathbf{x}^{\mathbf{mults}(\lambda)}\right)_{\lambda \in \mathrm{Par}}$ is a reindexing of this basis $(\mathbf{x}^\alpha)_{\alpha \in \mathrm{WC}}$ (since $\mathbf{mults} : \mathrm{Par} \to \mathrm{WC}$ is a bijection), and thus must also be a basis of the $\mathbf{k}$-module $\mathbf{k}[x_1, x_2, x_3, \ldots]$ (since a reindexing of a basis of a $\mathbf{k}$-module is always a basis itself). In view of $(\mathbf{x}_\lambda)_{\lambda \in \mathrm{Par}} = \left(\mathbf{x}^{\mathbf{mults}(\lambda)}\right)_{\lambda \in \mathrm{Par}}$, we can rewrite this as follows: The family $(\mathbf{x}_\lambda)_{\lambda \in \mathrm{Par}}$ is a basis of the $\mathbf{k}$-module $\mathbf{k}[x_1, x_2, x_3, \ldots]$. Hence, this family $(\mathbf{x}_\lambda)_{\lambda \in \mathrm{Par}}$ is $\mathbf{k}$-linearly independent and spans the $\mathbf{k}$-module $\mathbf{k}[x_1, x_2, x_3, \ldots]$.

Let us now step to the solution of Exercise 2.2.14:

(a) Let us use the following notation: If U is any $\mathbf{k}$-module, and if $(u_i)_{i \in I}$ is any family of elements of U, then $\langle u_i \mid i \in I \rangle_{\mathbf{k}}$ shall denote the $\mathbf{k}$-submodule of U spanned by this family $(u_i)_{i \in I}$.

We know that the family $(\mathbf{x}_\lambda)_{\lambda \in \mathrm{Par}}$ spans the $\mathbf{k}$-module $\mathbf{k}[x_1, x_2, x_3, \ldots]$. In other words,

$$\mathbf{k}[x_1, x_2, x_3, \ldots] = \langle \mathbf{x}_\lambda \mid \lambda \in \mathrm{Par} \rangle_{\mathbf{k}}.$$

[567] *Proof of (13.47.2):* Let $\lambda \in \mathrm{Par}$. Then, λ_p is a positive integer for each $p \in \{1, 2, \ldots, \ell(\lambda)\}$.

We have $\lambda = \left(\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}\right)$, and the entries $\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}$ of λ are positive integers, whereas each integer $p > \ell(\lambda)$ satisfies $\lambda_p = 0$. Thus, the parts of λ are $\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}$ (since a *part* of a partition means a nonzero entry of the partition). For each $i \in \{1, 2, 3, \ldots\}$, we have

$$\begin{aligned} m_i(\lambda) &= (\text{the multiplicity of } i \text{ in } \lambda) \qquad (\text{by the definition of } m_i(\lambda)) \\ &= (\text{the number of parts of } \lambda \text{ equal to } i) \\ &= (\text{the number of } p \in \{1, 2, \ldots, \ell(\lambda)\} \text{ satisfying } \lambda_p = i) \end{aligned}$$

(since the parts of λ are $\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}$). Hence, for each $i \in \{1, 2, 3, \ldots\}$, we have

$$(\text{the number of } p \in \{1, 2, \ldots, \ell(\lambda)\} \text{ satisfying } \lambda_p = i) = m_i(\lambda). \tag{13.47.3}$$

The definition of **mults** yields $\mathbf{mults}(\lambda) = (m_1(\lambda), m_2(\lambda), m_3(\lambda), \ldots)$. Thus, the definition of $\mathbf{x}^{\mathbf{mults}(\lambda)}$ yields

$$\mathbf{x}^{\mathbf{mults}(\lambda)} = x_1^{m_1(\lambda)} x_2^{m_2(\lambda)} x_3^{m_3(\lambda)} \cdots = \prod_{i=1}^{\infty} x_i^{m_i(\lambda)}. \tag{13.47.4}$$

But the definition of $\mathbf{x}_\lambda$ yields

$$\mathbf{x}_\lambda = x_{\lambda_1} x_{\lambda_2} \cdots x_{\lambda_{\ell(\lambda)}} = \prod_{p \in \{1, 2, \ldots, \ell(\lambda)\}} x_{\lambda_p} = \prod_{i=1}^{\infty} \prod_{\substack{p \in \{1, 2, \ldots, \ell(\lambda)\}; \\ \lambda_p = i}} x_{\lambda_p}$$

(here, we have split the product according to the value of λ_p, since λ_p is a positive integer for each $p \in \{1, 2, \ldots, \ell(\lambda)\}$). Hence,

$$\mathbf{x}_\lambda = \prod_{i=1}^{\infty} \prod_{\substack{p \in \{1, 2, \ldots, \ell(\lambda)\}; \\ \lambda_p = i}} \underbrace{x_{\lambda_p}}_{\substack{= x_i \\ (\text{since } \lambda_p = i)}} = \prod_{i=1}^{\infty} \underbrace{\prod_{\substack{p \in \{1, 2, \ldots, \ell(\lambda)\}; \\ \lambda_p = i}} x_i}_{\substack{= x_i^{(\text{the number of } p \in \{1, 2, \ldots, \ell(\lambda)\} \text{ satisfying } \lambda_p = i)} = x_i^{m_i(\lambda)} \\ (\text{by (13.47.3)})}} = \prod_{i=1}^{\infty} x_i^{m_i(\lambda)}.$$

Comparing this with (13.47.4), we obtain $\mathbf{x}_\lambda = \mathbf{x}^{\mathbf{mults}(\lambda)}$. This proves (13.47.2).

We have

$$f\left(\mathbf{x}_\lambda\right) = v_\lambda \qquad \text{for any } \lambda \in \operatorname{Par} \tag{13.47.5}$$

[568].

But A is commutative; hence,

$$\begin{aligned}
&\left(\text{the } \mathbf{k}\text{-subalgebra of } A \text{ generated by } v_1, v_2, v_3, \ldots\right) \\
&= \left\{ \underbrace{P\left(v_1, v_2, v_3, \ldots\right)}_{\substack{=f(P) \\ \text{(by (13.47.1))}}} \ \mid \ P \in \mathbf{k}\left[x_1, x_2, x_3, \ldots\right] \right\} \\
&= \left\{ f\left(P\right) \ \mid \ P \in \mathbf{k}\left[x_1, x_2, x_3, \ldots\right] \right\} = f\left(\underbrace{\mathbf{k}\left[x_1, x_2, x_3, \ldots\right]}_{=\left\langle \mathbf{x}_\lambda \ \mid \ \lambda \in \operatorname{Par} \right\rangle_{\mathbf{k}}} \right) \\
&= f\left(\left\langle \mathbf{x}_\lambda \ \mid \ \lambda \in \operatorname{Par} \right\rangle_{\mathbf{k}}\right) = \left\langle \underbrace{f\left(\mathbf{x}_\lambda\right)}_{\substack{=v_\lambda \\ \text{(by (13.47.5))}}} \ \mid \ \lambda \in \operatorname{Par} \right\rangle_{\mathbf{k}} \qquad \left(\text{since the map } f \text{ is } \mathbf{k}\text{-linear}\right) \\
&= \left\langle v_\lambda \ \mid \ \lambda \in \operatorname{Par} \right\rangle_{\mathbf{k}} = \left(\text{the } \mathbf{k}\text{-submodule of } A \text{ spanned by the family } \left(v_\lambda\right)_{\lambda \in \operatorname{Par}}\right).
\end{aligned}$$

This solves Exercise 2.2.14(a).

(b) We have the following chain of logical equivalences:

$$\begin{aligned}
&\left(\text{the elements } v_1, v_2, v_3, \ldots \text{ generate the } \mathbf{k}\text{-algebra } A\right) \\
\Longleftrightarrow\ &\left(\text{the } \mathbf{k}\text{-subalgebra of } A \text{ generated by } v_1, v_2, v_3, \ldots \text{ is } A\right) \\
\Longleftrightarrow\ &\left(\text{the } \mathbf{k}\text{-submodule of } A \text{ spanned by the family } \left(v_\lambda\right)_{\lambda \in \operatorname{Par}} \text{ is } A\right) \\
&\left(\begin{array}{c} \text{since Exercise 2.2.14(a) shows that} \\ \text{the } \mathbf{k}\text{-subalgebra of } A \text{ generated by } v_1, v_2, v_3, \ldots \\ \text{is the } \mathbf{k}\text{-submodule of } A \text{ spanned by the family } \left(v_\lambda\right)_{\lambda \in \operatorname{Par}} \end{array}\right) \\
\Longleftrightarrow\ &\left(\text{the family } \left(v_\lambda\right)_{\lambda \in \operatorname{Par}} \text{ spans the } \mathbf{k}\text{-module } A\right).
\end{aligned}$$

This solves Exercise 2.2.14(b).

(c) We shall prove the "$\Longrightarrow$" and the "$\Longleftarrow$" directions of Exercise 2.2.14(c) separately:

$\Longrightarrow$: Assume that the elements $v_1, v_2, v_3, \ldots$ are algebraically independent over $\mathbf{k}$. We must show that the family $\left(v_\lambda\right)_{\lambda \in \operatorname{Par}}$ is $\mathbf{k}$-linearly independent.

Let $\left(a_\lambda\right)_{\lambda \in \operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ be a family of scalars such that (all but finitely many $\lambda \in \operatorname{Par}$ satisfy $a_\lambda = 0$) and $\sum_{\lambda \in \operatorname{Par}} a_\lambda v_\lambda = 0$. We shall show that $\left(a_\lambda\right)_{\lambda \in \operatorname{Par}} = \left(0\right)_{\lambda \in \operatorname{Par}}$.

[568] *Proof of (13.47.5):* Let $\lambda \in \operatorname{Par}$. Then, the definition of $\mathbf{x}_\lambda$ yields $\mathbf{x}_\lambda = x_{\lambda_1} x_{\lambda_2} \cdots x_{\lambda_{\ell(\lambda)}}$. Applying the map f to both sides of this equality, we obtain

$$\begin{aligned}
f\left(\mathbf{x}_\lambda\right) &= f\left(x_{\lambda_1} x_{\lambda_2} \cdots x_{\lambda_{\ell(\lambda)}}\right) = f\left(x_{\lambda_1}\right) f\left(x_{\lambda_2}\right) \cdots f\left(x_{\lambda_{\ell(\lambda)}}\right) \qquad \left(\text{since } f \text{ is a } \mathbf{k}\text{-algebra homomorphism}\right) \\
&= \prod_{i=1}^{\ell(\lambda)} \underbrace{f\left(x_{\lambda_i}\right)}_{\substack{=v_{\lambda_i} \\ \text{(by the definition of } f\text{)}}} = \prod_{i=1}^{\ell(\lambda)} v_{\lambda_i} = v_{\lambda_1} v_{\lambda_2} \cdots v_{\lambda_{\ell(\lambda)}}.
\end{aligned}$$

Comparing this with

$$v_\lambda = v_{\lambda_1} v_{\lambda_2} \cdots v_{\lambda_{\ell(\lambda)}} \qquad \left(\text{by the definition of } v_\lambda\right),$$

we obtain $f\left(\mathbf{x}_\lambda\right) = v_\lambda$. This proves (13.47.5).

Define a polynomial $P \in \mathbf{k}[x_1, x_2, x_3, \ldots]$ by $P = \sum_{\lambda \in \operatorname{Par}} a_\lambda \mathbf{x}_\lambda$. Then,

$$f\left(\underbrace{P}_{=\sum_{\lambda\in\operatorname{Par}} a_\lambda \mathbf{x}_\lambda}\right) = f\left(\sum_{\lambda\in\operatorname{Par}} a_\lambda \mathbf{x}_\lambda\right) = \sum_{\lambda\in\operatorname{Par}} a_\lambda \underbrace{f(\mathbf{x}_\lambda)}_{\substack{=v_\lambda \\ \text{(by (13.47.5))}}} \qquad \text{(since the map } f \text{ is } \mathbf{k}\text{-linear)}$$
$$= \sum_{\lambda\in\operatorname{Par}} a_\lambda v_\lambda = 0.$$

Comparing this with (13.47.1), we obtain $P(v_1, v_2, v_3, \ldots) = 0$. This entails $P = 0$, because the elements $v_1, v_2, v_3, \ldots$ are algebraically independent. Comparing this with $P = \sum_{\lambda\in\operatorname{Par}} a_\lambda \mathbf{x}_\lambda$, we obtain $\sum_{\lambda\in\operatorname{Par}} a_\lambda \mathbf{x}_\lambda = 0$. But since the family $(\mathbf{x}_\lambda)_{\lambda\in\operatorname{Par}}$ is $\mathbf{k}$-linearly independent, this entails that $(a_\lambda)_{\lambda\in\operatorname{Par}} = (0)_{\lambda\in\operatorname{Par}}$.

Forget that we fixed $(a_\lambda)_{\lambda\in\operatorname{Par}}$. We thus have proved that if $(a_\lambda)_{\lambda\in\operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ is a family of scalars such that (all but finitely many $\lambda \in \operatorname{Par}$ satisfy $a_\lambda = 0$) and $\sum_{\lambda\in\operatorname{Par}} a_\lambda v_\lambda = 0$, then $(a_\lambda)_{\lambda\in\operatorname{Par}} = (0)_{\lambda\in\operatorname{Par}}$. In other words, the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is $\mathbf{k}$-linearly independent. This proves the "$\Longrightarrow$" direction of Exercise 2.2.14(c).

$\Longleftarrow$: Assume that the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is $\mathbf{k}$-linearly independent. We shall show that the elements $v_1, v_2, v_3, \ldots$ are algebraically independent over $\mathbf{k}$.

Indeed, let $P \in \mathbf{k}[x_1, x_2, x_3, \ldots]$ be a polynomial that satisfies $P(v_1, v_2, v_3, \ldots) = 0$. We shall show that $P = 0$.

Recall that the family $(\mathbf{x}_\lambda)_{\lambda\in\operatorname{Par}}$ spans the $\mathbf{k}$-module $\mathbf{k}[x_1, x_2, x_3, \ldots]$. Hence, we can write the polynomial $P \in \mathbf{k}[x_1, x_2, x_3, \ldots]$ as a $\mathbf{k}$-linear combination of this family. In other words, there exists a family $(a_\lambda)_{\lambda\in\operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ of scalars such that (all but finitely many $\lambda \in \operatorname{Par}$ satisfy $a_\lambda = 0$) and $P = \sum_{\lambda\in\operatorname{Par}} a_\lambda \mathbf{x}_\lambda$. Consider this $(a_\lambda)_{\lambda\in\operatorname{Par}}$.

Applying the map f to both sides of the equality $P = \sum_{\lambda\in\operatorname{Par}} a_\lambda \mathbf{x}_\lambda$, we obtain

$$f(P) = f\left(\sum_{\lambda\in\operatorname{Par}} a_\lambda \mathbf{x}_\lambda\right) = \sum_{\lambda\in\operatorname{Par}} a_\lambda \underbrace{f(\mathbf{x}_\lambda)}_{\substack{=v_\lambda \\ \text{(by (13.47.5))}}} \qquad \text{(since the map } f \text{ is } \mathbf{k}\text{-linear)}$$
$$= \sum_{\lambda\in\operatorname{Par}} a_\lambda v_\lambda.$$

But (13.47.1) yields

$$f(P) = P(v_1, v_2, v_3, \ldots) = 0.$$

Comparing these two equalities, we obtain $\sum_{\lambda\in\operatorname{Par}} a_\lambda v_\lambda = 0$. This entails that $(a_\lambda)_{\lambda\in\operatorname{Par}} = (0)_{\lambda\in\operatorname{Par}}$ (since the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is $\mathbf{k}$-linearly independent). In other words, $a_\lambda = 0$ for each $\lambda \in \operatorname{Par}$. Hence, $P = \sum_{\lambda\in\operatorname{Par}} \underbrace{a_\lambda}_{=0} \mathbf{x}_\lambda = \sum_{\lambda\in\operatorname{Par}} 0\mathbf{x}_\lambda = 0$.

Now, forget that we fixed P. We thus have showed that every polynomial $P \in \mathbf{k}[x_1, x_2, x_3, \ldots]$ satisfying $P(v_1, v_2, v_3, \ldots) = 0$ must satisfy $P = 0$. In other words, the elements $v_1, v_2, v_3, \ldots$ are algebraically independent over $\mathbf{k}$. This proves the "$\Longleftarrow$" direction of Exercise 2.2.14(c).

Thus, both "$\Longrightarrow$" and "$\Longleftarrow$" directions of Exercise 2.2.14(c) are solved.

13.48. **Solution to Exercise 2.2.15.** *Solution to Exercise 2.2.15.* Before we start solving the exercise, let us recall our notion of a "monomial". For us, a *pure monomial* is (formally speaking) just a symbol $\mathbf{x}^\alpha$ indexed by a weak composition α. (Thus, pure monomials are combinatorial objects; in particular, they have nothing to do with the ground ring $\mathbf{k}$ [569], and do not "come with coefficients".)

We let Mon be the set of all pure monomials. We define the product of two pure monomials $\mathbf{x}^\alpha$ and $\mathbf{x}^\beta$ by $\mathbf{x}^\alpha \mathbf{x}^\beta = \mathbf{x}^{\alpha+\beta}$, where $\alpha+\beta$ denotes the entrywise sum of the two weak compositions α and β (in other words, if $\alpha = (\alpha_1, \alpha_2, \alpha_3, \ldots)$ and $\beta = (\beta_1, \beta_2, \beta_3, \ldots)$, then $\alpha + \beta = (\alpha_1 + \beta_1, \alpha_2 + \beta_2, \alpha_3 + \beta_3, \ldots)$). This notion

[569] In particular, the pure monomials $\mathbf{x}^\alpha$ for different weak compositions α are distinct, although their images in the polynomial ring $\mathbf{k}[\mathbf{x}]$ are equal when $\mathbf{k} = 0$.

of product makes the set Mon of all pure monomials into a monoid. The neutral element of this monoid Mon is the pure monomial $\mathbf{x}^{(0,0,0,\ldots)}$, which we denote by 1. Whenever i is a positive integer, we write x_i for the pure monomial $\mathbf{x}^{t_i}$, where t_i is the weak composition $(\delta_{1,i}, \delta_{2,i}, \delta_{3,i}, \ldots) = \left(\underbrace{0, 0, \ldots, 0}_{i-1 \text{ zeroes}}, 1, 0, 0, 0, \ldots\right)$. This notation allows us to rewrite any pure monomial $\mathbf{x}^\alpha$ in the form $x_1^{\alpha_1} x_2^{\alpha_2} x_3^{\alpha_3} \cdots = \prod_{i \geq 1} x_i^{\alpha_i}$, where α is written in the form $\alpha = (\alpha_1, \alpha_2, \alpha_3, \ldots)$.

So far we have only discussed pure monomials, but not the actual monomials we encounter in polynomial rings or rings of power series. In practice, however, most authors (including us) identify pure monomials with actual monomials. Let us now introduce this identification.

For each weak composition α, we identify the pure monomial $\mathbf{x}^\alpha \in \operatorname{Mon}$ with the monomial $\mathbf{x}^\alpha$ in the polynomial ring $\mathbf{k}[\mathbf{x}]$. This identification is mostly harmless, because the map

$$\operatorname{Mon} \to \mathbf{k}[\mathbf{x}], \qquad \mathbf{x}^\alpha \mapsto \mathbf{x}^\alpha$$

is a monoid homomorphism (from Mon to the multiplicative monoid of $\mathbf{k}[\mathbf{x}]$). [570] Using this injectivity, we thus can consider every monomial $\mathbf{x}^\alpha \in \operatorname{Mon}$ as an element of $\mathbf{k}[\mathbf{x}]$, and thus also as an element of $\mathbf{k}[[\mathbf{x}]]$. Whenever we write sums of monomials (such as $\mathbf{x}^\alpha + \mathbf{x}^\beta$ or $\sum_{\mathfrak{m} \in \operatorname{Mon}} \mathfrak{m}$), we always mean these sums to be computed in $\mathbf{k}[\mathbf{x}]$ or $\mathbf{k}[[\mathbf{x}]]$.

For any pure monomial $\mathbf{x}^\alpha$, we let $\deg(\mathbf{x}^\alpha)$ denote the nonnegative integer $\alpha_1 + \alpha_2 + \alpha_3 + \cdots$. This integer is called the *degree* of the monomial $\mathbf{x}^\alpha$.

Now, we notice that every pure monomial $\mathfrak{m} \in \operatorname{Mon}$ can be uniquely represented in the form $\mathbf{x}^\alpha$ for a weak composition α. Hence, we can substitute $\mathbf{x}^\alpha$ for $\mathfrak{m}$ in the sum $\sum_{\mathfrak{m} \in \operatorname{Mon}} \mathfrak{m} t^{\deg \mathfrak{m}}$. We thus obtain

$$\sum_{\mathfrak{m} \in \operatorname{Mon}} \mathfrak{m} t^{\deg \mathfrak{m}} = \sum_{\substack{\alpha \text{ is a weak} \\ \text{composition}}} \mathbf{x}^\alpha t^{\deg(\mathbf{x}^\alpha)} = \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots) \text{ is a weak} \\ \text{composition}}} \underbrace{\mathbf{x}^{(\alpha_1,\alpha_2,\alpha_3,\ldots)}}_{=\prod_{i\geq 1} x_i^{\alpha_i}} \underbrace{t^{\deg\left(\mathbf{x}^{(\alpha_1,\alpha_2,\alpha_3,\ldots)}\right)}}_{\substack{=t^{\alpha_1+\alpha_2+\alpha_3+\cdots} \\ (\text{since } \deg\left(\mathbf{x}^{(\alpha_1,\alpha_2,\alpha_3,\ldots)}\right)=\alpha_1+\alpha_2+\alpha_3+\cdots)}}$$

$$\left(\text{here, we renamed the summation index } \alpha \text{ as } (\alpha_1, \alpha_2, \alpha_3, \ldots)\right)$$

$$= \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots) \text{ is a weak} \\ \text{composition}}} \left(\prod_{i \geq 1} x_i^{\alpha_i}\right) \underbrace{t^{\alpha_1+\alpha_2+\alpha_3+\cdots}}_{=t^{\sum_{i\geq 1}\alpha_i}=\prod_{i\geq 1} t^{\alpha_i}} = \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots) \text{ is a weak} \\ \text{composition}}} \underbrace{\left(\prod_{i \geq 1} x_i^{\alpha_i}\right)\left(\prod_{i\geq 1} t^{\alpha_i}\right)}_{=\prod_{i\geq 1}\left(x_i^{\alpha_i} t^{\alpha_i}\right)}$$

$$= \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots) \text{ is a weak} \\ \text{composition}}} \prod_{i \geq 1} \underbrace{\left(x_i^{\alpha_i} t^{\alpha_i}\right)}_{=(x_i t)^{\alpha_i}} = \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots) \text{ is a weak} \\ \text{composition}}} \prod_{i \geq 1} (x_i t)^{\alpha_i}$$

$$= \sum_{\substack{(k_1,k_2,k_3,\ldots) \text{ is a weak} \\ \text{composition}}} \prod_{i \geq 1} (x_i t)^{k_i}$$

(here, we renamed the summation index $(\alpha_1, \alpha_2, \alpha_3, \ldots)$ as $(k_1, k_2, k_3, \ldots)$). Compared with

$$\underbrace{\prod_{i=1}^{\infty}}_{=\prod_{i\geq 1}} \underbrace{(1 - x_i t)^{-1}}_{\substack{=\sum_{k\in\mathbb{N}} (x_i t)^k \\ (\text{by the formula for the} \\ \text{geometric series})}} = \prod_{i \geq 1} \sum_{k \in \mathbb{N}} (x_i t)^k = \sum_{\substack{(k_1,k_2,k_3,\ldots) \text{ is a weak} \\ \text{composition}}} \prod_{i \geq 1} (x_i t)^{k_i}$$

$$(\text{by the product rule}),$$

this yields

$$\sum_{\mathfrak{m} \in \operatorname{Mon}} \mathfrak{m} t^{\deg \mathfrak{m}} = \prod_{i=1}^{\infty} (1 - x_i t)^{-1}. \qquad (13.48.1)$$

[570] Also, this map is injective unless $\mathbf{k} = 0$. However, we do not need the injectivity of this map, because we will not derive any equalities between pure monomials from equalities between monomials in $\mathbf{k}[\mathbf{x}]$.

On the other hand, every pure monomial $\mathfrak{m} \in \operatorname{Mon}$ can be uniquely represented in the form $x_{i_1} x_{i_2} \cdots x_{i_n}$ for some $n \in \mathbb{N}$ and some weakly increasing n-tuple $(i_1, i_2, \ldots, i_n)$ of positive integers.[571] Hence, we can substitute $x_{i_1} x_{i_2} \cdots x_{i_n}$ for $\mathfrak{m}$ in the sum $\sum_{\mathfrak{m} \in \operatorname{Mon}} \mathfrak{m} t^{\deg \mathfrak{m}}$. We thus obtain

$$\begin{aligned}
\sum_{\mathfrak{m} \in \operatorname{Mon}} \mathfrak{m} t^{\deg \mathfrak{m}} &= \sum_{n \in \mathbb{N}} \underbrace{\sum_{\substack{(i_1, i_2, \ldots, i_n) \text{ is a} \\ \text{weakly increasing} \\ n\text{-tuple of positive integers}}}}_{= \sum_{i_1 \leq i_2 \leq \cdots \leq i_n}} (x_{i_1} x_{i_2} \cdots x_{i_n}) \underbrace{t^{\deg\left(x_{i_1} x_{i_2} \cdots x_{i_n}\right)}}_{\substack{= t^n \\ (\text{since } \deg\left(x_{i_1} x_{i_2} \cdots x_{i_n}\right) = n)}} \\
&= \sum_{n \in \mathbb{N}} \sum_{i_1 \leq i_2 \leq \cdots \leq i_n} (x_{i_1} x_{i_2} \cdots x_{i_n}) t^n = \sum_{n \in \mathbb{N}} \underbrace{\left(\sum_{i_1 \leq i_2 \leq \cdots \leq i_n} x_{i_1} x_{i_2} \cdots x_{i_n} \right)}_{\substack{= h_n \\ (\text{since (2.2.3) yields} \\ h_n = \sum_{i_1 \leq i_2 \leq \cdots \leq i_n} x_{i_1} x_{i_2} \cdots x_{i_n})}} t^n \\
&= \sum_{n \in \mathbb{N}} \underbrace{h_n}_{= h_n(\mathbf{x})} t^n = \sum_{n \geq 0} h_n(\mathbf{x}) t^n = \underbrace{h_0(\mathbf{x})}_{= h_0 = 1} + h_1(\mathbf{x}) t + h_2(\mathbf{x}) t^2 + \cdots \\
&= 1 + h_1(\mathbf{x}) t + h_2(\mathbf{x}) t^2 + \cdots .
\end{aligned}$$

Compared with (13.48.1), this yields

$$\prod_{i=1}^{\infty} (1 - x_i t)^{-1} = 1 + h_1(\mathbf{x}) t + h_2(\mathbf{x}) t^2 + \cdots = \sum_{n \geq 0} h_n(\mathbf{x}) t^n.$$

Thus, the first of the two identities that we need to prove is proven.

Next, let us define the notion of a *squarefree monomial*. Indeed, let us say that a pure monomial $\mathbf{x}^\alpha \in \operatorname{Mon}$ is *squarefree* if and only if every entry of the weak composition α belongs to $\{0, 1\}$. Thus, of course, every squarefree monomial $\mathfrak{m} \in \operatorname{Mon}$ can be uniquely represented in the form $\mathbf{x}^\alpha$ for a weak composition α whose every entry belongs to $\{0, 1\}$. Hence, we can substitute $\mathbf{x}^\alpha$ for $\mathfrak{m}$ in the sum $\sum_{\substack{\mathfrak{m} \in \operatorname{Mon}; \\ \mathfrak{m} \text{ is squarefree}}} \mathfrak{m} t^{\deg \mathfrak{m}}$. We thus

[571] Indeed, this n-tuple $(i_1, i_2, \ldots, i_n)$ can be found by writing $\mathfrak{m}$ as a product of x_j's, and sorting those x_j's in weakly increasing order.

obtain

$$\begin{aligned}
&\sum_{\substack{\mathfrak{m}\in\operatorname{Mon};\\ \mathfrak{m}\text{ is squarefree}}} \mathfrak{m}t^{\deg\mathfrak{m}} \\
&= \underbrace{\sum_{\substack{\alpha\text{ is a weak}\\ \text{composition;}\\ \text{every entry of }\alpha\\ \text{belongs to }\{0,1\}}}}_{\substack{=\sum_{\substack{\alpha\in\{0,1\}^\infty\text{ is a weak}\\ \text{composition}}}\\ \text{(because if }\alpha\text{ is a weak}\\ \text{composition, then the statement}\\ \text{(every entry of }\alpha\text{ belongs to }\{0,1\})\\ \text{is equivalent to }(\alpha\in\{0,1\}^\infty))}} \mathbf{x}^\alpha t^{\deg(\mathbf{x}^\alpha)} = \sum_{\substack{\alpha\in\{0,1\}^\infty\text{ is a weak}\\ \text{composition}}} \mathbf{x}^\alpha t^{\deg(\mathbf{x}^\alpha)} \\
&= \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots)\in\{0,1\}^\infty\text{ is a}\\ \text{weak composition}}} \underbrace{\mathbf{x}^{(\alpha_1,\alpha_2,\alpha_3,\ldots)}}_{=\prod_{i\geq 1}x_i^{\alpha_i}} \underbrace{t^{\deg\left(\mathbf{x}^{(\alpha_1,\alpha_2,\alpha_3,\ldots)}\right)}}_{\substack{=t^{\alpha_1+\alpha_2+\alpha_3+\cdots}\\ \text{(since }\deg\left(\mathbf{x}^{(\alpha_1,\alpha_2,\alpha_3,\ldots)}\right)=\alpha_1+\alpha_2+\alpha_3+\cdots)}} \\
&\qquad \left(\text{here, we renamed the summation index }\alpha\text{ as }(\alpha_1,\alpha_2,\alpha_3,\ldots)\right) \\
&= \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots)\in\{0,1\}^\infty\text{ is a}\\ \text{weak composition}}} \left(\prod_{i\geq 1}x_i^{\alpha_i}\right) \underbrace{t^{\alpha_1+\alpha_2+\alpha_3+\cdots}}_{=t^{\sum_{i\geq 1}\alpha_i}=\prod_{i\geq 1}t^{\alpha_i}} = \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots)\in\{0,1\}^\infty\text{ is a}\\ \text{weak composition}}} \underbrace{\left(\prod_{i\geq 1}x_i^{\alpha_i}\right)\left(\prod_{i\geq 1}t^{\alpha_i}\right)}_{=\prod_{i\geq 1}\left(x_i^{\alpha_i}t^{\alpha_i}\right)} \\
&= \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots)\in\{0,1\}^\infty\text{ is a}\\ \text{weak composition}}} \prod_{i\geq 1} \underbrace{\left(x_i^{\alpha_i}t^{\alpha_i}\right)}_{=(x_it)^{\alpha_i}} = \sum_{\substack{(\alpha_1,\alpha_2,\alpha_3,\ldots)\in\{0,1\}^\infty\text{ is a}\\ \text{weak composition}}} \prod_{i\geq 1}(x_it)^{\alpha_i} \\
&= \sum_{\substack{(k_1,k_2,k_3,\ldots)\in\{0,1\}^\infty\text{ is a}\\ \text{weak composition}}} \prod_{i\geq 1}(x_it)^{k_i}
\end{aligned}$$

(here, we renamed the summation index $(\alpha_1,\alpha_2,\alpha_3,\ldots)$ as $(k_1,k_2,k_3,\ldots)$). Compared with

$$\underbrace{\prod_{i=1}^{\infty}}_{=\prod_{i\geq 1}} \underbrace{(1+x_it)}_{\substack{=\sum_{k\in\{0,1\}}(x_it)^k\\ \text{(since }\sum_{k\in\{0,1\}}(x_it)^k\\ =(x_it)^0+(x_it)^1=1+x_it\\ \text{(since }(x_it)^0=1\text{ and }(x_it)^1=x_it))}} = \prod_{i\geq 1}\sum_{k\in\{0,1\}}(x_it)^k = \sum_{\substack{(k_1,k_2,k_3,\ldots)\in\{0,1\}^\infty\text{ is a}\\ \text{weak composition}}} \prod_{i\geq 1}(x_it)^{k_i}$$
$$(\text{by the product rule}),$$

this yields

$$\sum_{\substack{\mathfrak{m}\in\operatorname{Mon};\\ \mathfrak{m}\text{ is squarefree}}} \mathfrak{m}t^{\deg\mathfrak{m}} = \prod_{i=1}^{\infty}(1+x_it). \tag{13.48.2}$$

On the other hand, every squarefree monomial $\mathfrak{m}\in\operatorname{Mon}$ can be uniquely represented in the form $x_{i_1}x_{i_2}\cdots x_{i_n}$ for some $n\in\mathbb{N}$ and some strictly increasing n-tuple $(i_1,i_2,\ldots,i_n)$ of positive integers.[572]

[572] *Proof.* This follows from the following observations:

- If $\mathfrak{m}\in\operatorname{Mon}$ is a squarefree monomial, then $\mathfrak{m}$ can be represented in the form $x_{i_1}x_{i_2}\cdots x_{i_n}$ for some $n\in\mathbb{N}$ and some strictly increasing n-tuple $(i_1,i_2,\ldots,i_n)$ of positive integers. (Indeed, we know already that every pure monomial $\mathfrak{m}\in\operatorname{Mon}$ can be uniquely represented in the form $x_{i_1}x_{i_2}\cdots x_{i_n}$ for some $n\in\mathbb{N}$ and some weakly increasing n-tuple $(i_1,i_2,\ldots,i_n)$ of positive integers. If $\mathfrak{m}$ is squarefree, then this n-tuple $(i_1,i_2,\ldots,i_n)$ must consist of n **distinct** integers (because otherwise, the product $x_{i_1}x_{i_2}\cdots x_{i_n}$ would fail to be squarefree, which would contradict the fact that $x_{i_1}x_{i_2}\cdots x_{i_n}=\mathfrak{m}$ is squarefree), and therefore is strictly increasing (because it is weakly increasing). Hence, every squarefree monomial $\mathfrak{m}$ can be be represented in the form $x_{i_1}x_{i_2}\cdots x_{i_n}$ for some $n\in\mathbb{N}$ and some strictly increasing n-tuple $(i_1,i_2,\ldots,i_n)$ of positive integers.)

Hence, we can substitute $x_{i_1}x_{i_2}\cdots x_{i_n}$ for $\mathfrak{m}$ in the sum $\sum\limits_{\substack{\mathfrak{m}\in\operatorname{Mon};\\ \mathfrak{m}\text{ is squarefree}}} \mathfrak{m}t^{\deg\mathfrak{m}}$. We thus obtain

$$\begin{aligned}
\sum_{\substack{\mathfrak{m}\in\operatorname{Mon};\\ \mathfrak{m}\text{ is squarefree}}} \mathfrak{m}t^{\deg\mathfrak{m}} &= \sum_{n\in\mathbb{N}} \underbrace{\sum_{\substack{(i_1,i_2,\ldots,i_n)\text{ is a}\\ \text{strictly increasing}\\ n\text{-tuple of positive integers}}}}_{=\sum_{i_1<i_2<\cdots<i_n}} \left(x_{i_1}x_{i_2}\cdots x_{i_n}\right) \underbrace{t^{\deg\left(x_{i_1}x_{i_2}\cdots x_{i_n}\right)}}_{\substack{=t^n\\ (\text{since }\deg\left(x_{i_1}x_{i_2}\cdots x_{i_n}\right)=n)}} \\
&= \sum_{n\in\mathbb{N}} \sum_{i_1<i_2<\cdots<i_n} \left(x_{i_1}x_{i_2}\cdots x_{i_n}\right) t^n = \sum_{n\in\mathbb{N}} \underbrace{\left(\sum_{i_1<i_2<\cdots<i_n} x_{i_1}x_{i_2}\cdots x_{i_n}\right)}_{\substack{=e_n\\ (\text{since (2.2.2) yields}\\ e_n=\sum_{i_1<i_2<\cdots<i_n} x_{i_1}x_{i_2}\cdots x_{i_n})}} t^n \\
&= \sum_{n\in\mathbb{N}} \underbrace{e_n}_{=e_n(\mathbf{x})} t^n = \sum_{n\geq 0} e_n\left(\mathbf{x}\right) t^n = \underbrace{e_0\left(\mathbf{x}\right)}_{=e_0=1} + e_1\left(\mathbf{x}\right) t + e_2\left(\mathbf{x}\right) t^2 + \cdots \\
&= 1 + e_1\left(\mathbf{x}\right) t + e_2\left(\mathbf{x}\right) t^2 + \cdots .
\end{aligned}$$

Compared with (13.48.2), this yields

$$\prod_{i=1}^{\infty}\left(1+x_it\right) = 1 + e_1\left(\mathbf{x}\right) t + e_2\left(\mathbf{x}\right) t^2 + \cdots = \sum_{n\geq 0} e_n\left(\mathbf{x}\right) t^n.$$

This completes the solution to Exercise 2.2.15.

13.49. **Solution to Exercise 2.3.4.** *Solution to Exercise 2.3.4.* (a) This is straightforward. If λ and μ are two partitions such that $\mu\subseteq\lambda$, and if $\mathcal{L}$ is any total order on the positive integers, then we say that an assignment T of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram of λ/μ is an *$\mathcal{L}$-column-strict tableau* if it is weakly $\mathcal{L}$-increasing left-to-right in rows, and strictly $\mathcal{L}$-increasing top-to-bottom in columns. (This definition of $\mathcal{L}$-column-strict tableaux clearly extends the definition given in Remark 2.2.5 for tableaux of shape λ.) Now, the analogue of Proposition 2.2.6 is the following statement:

Proposition 13.49.1. *Let λ and μ be two partitions such that $\mu\subseteq\lambda$. Then, for any total order $\mathcal{L}$ on the positive integers,*

$$s_{\lambda/\mu} = \sum_T \mathbf{x}^{\operatorname{cont}(T)}$$

as T runs through all $\mathcal{L}$-column-strict tableaux of shape λ/μ.

The proof of Proposition 13.49.1 is completely analogous to the proof of Proposition 2.2.6.

(b) If α and β are two partitions such that $\beta\subseteq\alpha$, then let $Y\left(\alpha/\beta\right)$ denote the skew Ferrers diagram α/β. This is a finite set of cells in $\{1,2,3,...\}^2$.

We know that the skew Ferrers diagram λ'/μ' can be obtained from the skew Ferrers diagram λ/μ by a 180° rotation. In other words, there exists a 180° rotation r such that $r\left(Y\left(\lambda/\mu\right)\right) = Y\left(\lambda'/\mu'\right)$. Consider this r.

Let $\mathcal{L}$ be the total order on the set of all positive integers which is defined by $\cdots <_{\mathcal{L}} 3 <_{\mathcal{L}} 2 <_{\mathcal{L}} 1$ (in other words, let $\mathcal{L}$ be the reverse of the usual total order on the set of all positive integers). Recall the definition

- If $\mathfrak{m}\in\operatorname{Mon}$ is a squarefree monomial, then the representation of $\mathfrak{m}$ in the form $x_{i_1}x_{i_2}\cdots x_{i_n}$ for some $n\in\mathbb{N}$ and some strictly increasing n-tuple $\left(i_1,i_2,\ldots,i_n\right)$ of positive integers is unique. (Indeed, even if we only require $\left(i_1,i_2,\ldots,i_n\right)$ to be weakly increasing rather than strictly increasing, then the representation is unique (because we know already that every pure monomial $\mathfrak{m}\in\operatorname{Mon}$ can be uniquely represented in the form $x_{i_1}x_{i_2}\cdots x_{i_n}$ for some $n\in\mathbb{N}$ and some weakly increasing n-tuple $\left(i_1,i_2,\ldots,i_n\right)$ of positive integers).)
- Every product of the form $x_{i_1}x_{i_2}\cdots x_{i_n}$ for some $n\in\mathbb{N}$ and some strictly increasing n-tuple $\left(i_1,i_2,\ldots,i_n\right)$ of positive integers is a squarefree monomial. (This is obvious, because the elements $i_1,i_2,\ldots,i_n$ of a strictly increasing n-tuple $\left(i_1,i_2,\ldots,i_n\right)$ are distinct.)

of $\mathcal{L}$-column-strict tableaux that we gave in the solution of part (a) of this exercise. According to this definition, an $\mathcal{L}$-column-strict tableau of shape λ'/μ' is an assignment of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram of λ'/μ' which is weakly $\mathcal{L}$-increasing left-to-right in rows, and strictly $\mathcal{L}$-increasing top-to-bottom in columns. Since "weakly $\mathcal{L}$-increasing" is the same as "weakly decreasing" (because $\mathcal{L}$ is the reverse of the usual total order on the set of all positive integers), and since "strictly $\mathcal{L}$-increasing" is the same as "strictly decreasing" (for the same reason), this rewrites as follows: An $\mathcal{L}$-column-strict tableau of shape λ'/μ' is an assignment of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram of λ'/μ' which is weakly decreasing left-to-right in rows, and strictly decreasing top-to-bottom in columns. Hence, if T is an $\mathcal{L}$-column-strict tableau of shape λ'/μ', then $T\circ r$ (this composition is well-defined[573]) is an assignment of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram of λ/μ which is weakly decreasing right-to-left in rows, and strictly decreasing bottom-to-top in columns[574]. In other words, if T is an $\mathcal{L}$-column-strict tableau of shape λ'/μ', then $T\circ r$ is an assignment of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram of λ/μ which is weakly increasing left-to-right in rows, and strictly increasing top-to-bottom in columns. In other words, if T is an $\mathcal{L}$-column-strict tableau of shape λ'/μ', then $T\circ r$ is a column-strict tableau (in the usual sense) of shape λ/μ. Hence, we have constructed a map

$$\{\mathcal{L}\text{-column-strict tableaux of shape } \lambda'/\mu'\} \to \{\text{column-strict tableaux of shape } \lambda/\mu\},$$

which sends every T to $T\circ r$. This map is easily seen to be a bijection. Therefore, we can substitute $T\circ r$ for T in the sum $\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)}$. We thus obtain

$$\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)} = \sum_{\substack{T \text{ is an } \mathcal{L}\text{-column-strict} \\ \text{tableau of shape } \lambda'/\mu'}} \underbrace{\mathbf{x}^{\operatorname{cont}(T\circ r)}}_{\substack{=\mathbf{x}^{\operatorname{cont}(T)} \\ \text{(since the multiset of entries} \\ \text{of } T\circ r \text{ is the multiset} \\ \text{of entries of } T)}}$$

$$= \sum_{\substack{T \text{ is an } \mathcal{L}\text{-column-strict} \\ \text{tableau of shape } \lambda'/\mu'}} \mathbf{x}^{\operatorname{cont}(T)}. \qquad (13.49.1)$$

But Proposition 13.49.1 (applied to λ' and μ' instead of λ and μ) yields

$$s_{\lambda'/\mu'} = \sum_T \mathbf{x}^{\operatorname{cont}(T)}$$

as T runs through all $\mathcal{L}$-column-strict tableaux of shape λ'/μ'. In other words,

$$s_{\lambda'/\mu'} = \sum_{\substack{T \text{ is an } \mathcal{L}\text{-column-strict} \\ \text{tableau of shape } \lambda'/\mu'}} \mathbf{x}^{\operatorname{cont}(T)} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)} \qquad (13.49.2)$$

(by (13.49.1)).

But the definition of $s_{\lambda/\mu}$ yields $s_{\lambda/\mu} = \sum_T \mathbf{x}^{\operatorname{cont}(T)}$, where the sum ranges over all column-strict tableaux T of shape λ/μ. In other words,

$$s_{\lambda/\mu} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)}.$$

Compared with (13.49.2), this yields $s_{\lambda/\mu} = s_{\lambda'/\mu'}$. This solves part (b) of the exercise.

---

[573] because T is an assignment of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram of λ'/μ', that is, a map $Y(\lambda'/\mu') \to \{1,2,3,\ldots\}$, whereas r is a map sending $Y(\lambda/\mu)$ to $Y(\lambda'/\mu')$

[574] because r is a 180° rotation, and thus interchanges "left-to-right" with "right-to-left" and interchanges "top-to-bottom" with "bottom-to-top"

13.50. **Solution to Exercise 2.3.5.** *Solution to Exercise 2.3.5.* If φ and ψ are two partitions such that $\psi \subseteq \varphi$, then let $Y(\varphi/\psi)$ denote the skew Ferrers diagram φ/ψ (this is a subset of $\{1,2,3,...\}^2$).

Whenever Z is a subset of $\mathbb{Z}^2$, we define a *column-strict Z-tableau* to be an assignment of entries in $\{1,2,3,...\}$ to the elements of Z which is weakly increasing left-to-right in rows and strictly increasing top-to-bottom in columns. It is clear that if φ and ψ are two partitions such that $\psi \subseteq \varphi$, then a column-strict tableau of shape φ/ψ is the same as a column-strict $Y(\varphi/\psi)$-tableau. We define the notation $\operatorname{cont}(T)$ (and therefore, $\mathbf{x}^{\operatorname{cont}(T)}$) for a column-strict Z-tableau T in the same way as it is defined for a column-strict tableau of shape λ/μ (for some partitions λ and μ).

The following is now more or less obvious:

Lemma 13.50.1. *Let φ and ψ be two partitions such that $\psi \subseteq \varphi$. Let Z be a subset of $\mathbb{Z}^2$. Assume that the skew Ferrers diagram φ/ψ can be obtained from Z by parallel translation. Then,*

$$s_{\varphi/\psi} = \sum_{\substack{T \text{ is a column-strict} \\ Z\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(T)}.$$

Proof of Lemma 13.50.1. Let R be the parallel translation which sends the set Z to $Y(\varphi/\psi)$.

The definition of $s_{\varphi/\psi}$ yields $s_{\varphi/\psi} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \varphi/\psi}} \mathbf{x}^{\operatorname{cont}(T)}$. It remains to prove that the right hand side of this equality equals $\sum_{\substack{T \text{ is a column-strict} \\ Z\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(T)}$. To achieve this, it is clearly enough to find a bijection

$$\Gamma : (\text{the set of all column-strict tableaux of shape } \varphi/\psi) \to (\text{the set of all column-strict } Z\text{-tableaux})$$

which satisfies

$$\left(\mathbf{x}^{\operatorname{cont}(\Gamma(T))} = \mathbf{x}^{\operatorname{cont}(T)} \qquad \text{for every column-strict tableau } T \text{ of shape } \varphi/\psi\right).$$

But this is very easy: The bijection Γ sends every column-strict tableau T of shape φ/ψ to the column-strict Z-tableau $T \circ R$. (The notation $T \circ R$ makes sense because T, being a column-strict tableau of shape φ/ψ, is an assignment of entries in $\{1,2,3,...\}$ to the cells of the skew Ferrers diagram φ/ψ, that is, a map $Y(\varphi/\psi) \to \{1,2,3,...\}$. Visually speaking, $T \circ R$ is the result of moving the tableau T so that it takes up the cells of Z rather than the cells of φ/ψ.) Lemma 13.50.1 is proven. □

Now, let us return to the solution of the exercise. Clearly, the subsets $F_{\text{rows}\leq k}$ and $F_{\text{rows}>k}$ of F are disjoint, and their union is F.

Lemma 13.50.1 (applied to α, β and $F_{\text{rows}\leq k}$ instead of φ, ψ and Z) yields

$$(13.50.1) \qquad s_{\alpha/\beta} = \sum_{\substack{T \text{ is a column-strict} \\ F_{\text{rows}\leq k}\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(T)} = \sum_{\substack{P \text{ is a column-strict} \\ F_{\text{rows}\leq k}\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(P)}$$

(here, we renamed the summation index T as P). Also, Lemma 13.50.1 (applied to γ, δ and $F_{\text{rows}>k}$ instead of φ, ψ and Z) yields

$$(13.50.2) \qquad s_{\gamma/\delta} = \sum_{\substack{T \text{ is a column-strict} \\ F_{\text{rows}>k}\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(T)} = \sum_{\substack{Q \text{ is a column-strict} \\ F_{\text{rows}>k}\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(Q)}$$

(here, we renamed the summation index T as Q). Multiplying the identities (13.50.1) and (13.50.2), we obtain

$$\begin{aligned} s_{\alpha/\beta}s_{\gamma/\delta} &= \left(\sum_{\substack{P \text{ is a column-strict} \\ F_{\text{rows}\leq k}\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(P)} \right) \left(\sum_{\substack{Q \text{ is a column-strict} \\ F_{\text{rows}>k}\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(Q)} \right) \\ &= \sum_{\substack{P \text{ is a column-strict} \\ F_{\text{rows}\leq k}\text{-tableau}}} \sum_{\substack{Q \text{ is a column-strict} \\ F_{\text{rows}>k}\text{-tableau}}} \mathbf{x}^{\operatorname{cont}(P)}\mathbf{x}^{\operatorname{cont}(Q)} \\ &= \sum_{\substack{(P,Q)\in \\ \left(\text{the set of all column-strict } F_{\text{rows}\leq k}\text{-tableaux}\right) \\ \times\left(\text{the set of all column-strict } F_{\text{rows}>k}\text{-tableaux}\right)}} \mathbf{x}^{\operatorname{cont}(P)}\mathbf{x}^{\operatorname{cont}(Q)}. \end{aligned} \tag{13.50.3}$$

On the other hand, the definition of $s_{\lambda/\mu}$ yields

$$s_{\lambda/\mu} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)}. \tag{13.50.4}$$

Our goal is to prove that the left-hand side of (13.50.4) equals the left-hand side of (13.50.3). For this, it is clearly enough to show that the right-hand side of (13.50.4) equals the right-hand side of (13.50.3). But to achieve this, it clearly suffices to exhibit a bijection

$$\begin{aligned} \Phi &: (\text{the set of all column-strict tableaux of shape } \lambda/\mu) \\ &\to (\text{the set of all column-strict } F_{\text{rows}\leq k}\text{-tableaux}) \times (\text{the set of all column-strict } F_{\text{rows}>k}\text{-tableaux}) \end{aligned}$$

which has the property that
(13.50.5)

$$\text{if } (P,Q) = \Phi(T) \text{ for some column-strict tableau } T \text{ of shape } \lambda/\mu, \text{ then } \mathbf{x}^{\operatorname{cont}(P)}\mathbf{x}^{\operatorname{cont}(Q)} = \mathbf{x}^{\operatorname{cont}(T)}.$$

We claim that such a bijection Φ can be defined by

$$\left(\Phi(T) = \left(T\mid_{F_{\text{rows}\leq k}}, T\mid_{F_{\text{rows}>k}}\right) \qquad \text{for every column-strict tableau } T \text{ of shape } \lambda/\mu\right). \tag{13.50.6}$$

Indeed, it is clear that we can define a map

$$\begin{aligned} \Phi &: (\text{the set of all column-strict tableaux of shape } \lambda/\mu) \\ &\to (\text{the set of all column-strict } F_{\text{rows}\leq k}\text{-tableaux}) \times (\text{the set of all column-strict } F_{\text{rows}>k}\text{-tableaux}) \end{aligned}$$

by (13.50.6), and that this map Φ satisfies (13.50.5). All that remains to be proven is that this map Φ is a bijection. It is clear that Φ is injective, so we only need to prove that Φ is surjective.

Let $(P,Q) \in$ (the set of all column-strict $F_{\text{rows}\leq k}$-tableaux)×(the set of all column-strict $F_{\text{rows}>k}$-tableaux) be arbitrary. We are going to prove that (P,Q) lies in the image of Φ.

Define a map $T : F \to \{1,2,3,...\}$ by setting

$$\left(T(p) = \begin{cases} P(p), & \text{if } p \in F_{\text{rows}\leq k}; \\ Q(p), & \text{if } p \in F_{\text{rows}>k} \end{cases} \qquad \text{for all } p \in F\right).$$

This map T is clearly well-defined (since the subsets $F_{\text{rows}\leq k}$ and $F_{\text{rows}>k}$ of F are disjoint, and their union is F), and thus is an assignment of entries in $\{1,2,3,...\}$ to the cells of the skew Ferrers diagram λ/μ (since F is the set of those cells). It furthermore satisfies $T\mid_{F_{\text{rows}\leq k}}= P$ and $T\mid_{F_{\text{rows}>k}}= Q$. We shall now show that this assignment T is a column-strict tableau of shape λ/μ.

This rests on the following observation:

> *Assertion A:* Let c and d be two cells lying in F. Assume that the cells c and d either lie in one and the same row, or lie in one and the same column. Then, either both c and d belong to $F_{\text{rows}\leq k}$, or both c and d belong to $F_{\text{rows}>k}$.

Assertion A is an easy consequence of our assumption that $\mu_k \geq \lambda_{k+1}$. [575] Now, we want to prove that T is a column-strict tableau of shape λ/μ. To do so, we need to check that T is weakly increasing left-to-right in rows, and strictly increasing top-to-bottom in columns. We will only prove the latter part of this statement, as the former part is proven analogously. So we are going to show that T is strictly increasing top-to-bottom in columns. In other words, we are going to show that if c and d are two cells of λ/μ lying in one and the same column, with d lying strictly further south than c, then $T(c) < T(d)$. Indeed, consider two such cells c and d. Assertion A shows that either both c and d belong to $F_{\text{rows}\leq k}$, or both c and d belong to $F_{\text{rows}>k}$. Let us WLOG assume that we are in the first of these two cases (the other case is exactly analogous). Then, both c and d belong to $F_{\text{rows}\leq k}$, so that we have $T(c) = \left(T\mid_{F_{\text{rows}\leq k}}\right)(c)$ and $T(d) = \left(T\mid_{F_{\text{rows}\leq k}}\right)(d)$. Since $T\mid_{F_{\text{rows}\leq k}} = P$, these two equalities rewrite as $T(c) = P(c)$ and $T(d) = P(d)$. But since P is strictly increasing top-to-bottom in columns (because P is a column-strict tableau), we have $P(c) < P(d)$, and thus $T(c) = P(c) < P(d) = T(d)$. Thus, we have proven that $T(c) < T(d)$. This completes the proof that T is a column-strict tableau of shape λ/μ. Hence, $\Phi(T)$ is well-defined, and the definition of $\Phi(T)$ shows that $\Phi(T) = \left(\underbrace{T\mid_{F_{\text{rows}\leq k}}}_{=P}, \underbrace{T\mid_{F_{\text{rows}>k}}}_{=Q}\right) = (P,Q)$. Thus, (P,Q) lies in the image of Φ.

Now, let us forget that we fixed (P,Q). We thus have shown that every $(P,Q) \in (\text{the set of all column-strict } F_{\text{rows}\leq k}\text{-tableaux}) \times (\text{the set of all column-strict } F_{\text{rows}>k}\text{-tableaux})$ lies in the image of Φ. In other words, the map Φ is surjective, which (as we know that Φ is injective) yields that Φ is a bijection. As explained above, this completes the solution of Exercise 2.3.5.

13.51. **Solution to Exercise 2.3.7.** *Solution to Exercise 2.3.7.* As usual, let T denote the twist map $\Lambda \otimes \Lambda \to \Lambda \otimes \Lambda$ (that is, the $\mathbf{k}$-linear map sending every $c \otimes d \in \Lambda \otimes \Lambda$ to $d \otimes c$). By the definition of "cocommutative", we know that the Hopf algebra Λ is cocommutative if and only if the diagram

(13.51.1)
$$\begin{tikzcd}
\Lambda \otimes \Lambda \arrow[rr, "T"] & & \Lambda \otimes \Lambda \\
& \Lambda \arrow[ul, "\Delta"] \arrow[ur, "\Delta"'] &
\end{tikzcd}$$

commutes. Hence, in order to solve Exercise 2.3.7(a), it is enough to check that the diagram (13.51.1) commutes.

The set $\{h_n\}_{n=1,2,\ldots}$ generates the $\mathbf{k}$-algebra Λ (due to Proposition 2.4.1). In other words, the set $\{h_1, h_2, h_3, \ldots\}$ is a generating set of the $\mathbf{k}$-algebra Λ.

By the axioms of a bialgebra, the comultiplication Δ of Λ is a $\mathbf{k}$-algebra homomorphism (since Λ is a bialgebra). Hence, $T \circ \Delta$ also is a $\mathbf{k}$-algebra homomorphism (since T and Δ are $\mathbf{k}$-algebra homomorphisms).

[575] *Proof of Assertion A:* Assume the contrary. Then, one of the cells c and d belongs to $F_{\text{rows}\leq k}$, whereas the other belongs to $F_{\text{rows}>k}$. We WLOG assume that c belongs to $F_{\text{rows}\leq k}$, whereas d belongs to $F_{\text{rows}>k}$ (since otherwise, we can simply switch c with d).

Write the cell c in the form (a,b), so that c lies in row a and column b. Write the cell d in the form (a',b'), so that d lies in row a' and column b'.

We have $(a,b) = c \in F_{\text{rows}\leq k}$, so that $a \leq k$ (by the definition of $F_{\text{rows}\leq k}$). We have $(a',b') = d \in F_{\text{rows}>k}$, so that $a' > k$ (by the definition of $F_{\text{rows}>k}$).

We have $a \leq k < a'$ (since $a' > k$), hence $a \neq a'$. Thus, the cells c and d lie in different rows (since the cell c lies in row a, whereas the cell d lies in row a'). As a consequence, the cells c and d must lie in one and the same column (since we assumed that the cells c and d either lie in one and the same row, or lie in one and the same column). In other words, $b = b'$ (since the cell c lies in column b, while the cell d lies in column b').

Now, $(a,b) = c \in F = Y(\lambda/\mu)$. By the definition of $Y(\lambda/\mu)$, this shows that $\mu_a < b \leq \lambda_a$. Similarly, $\mu_{a'} < b' \leq \lambda_{a'}$.

We have $a' > k$, hence $a' \geq k+1$ (since a' and k are integers), thus $k+1 \leq a'$.

Since μ is a partition, we have $\mu_1 \geq \mu_2 \geq \mu_3 \geq \ldots$. Hence, $\mu_a \geq \mu_k$ (since $a \leq k$). Thus, $\mu_a \geq \mu_k \geq \lambda_{k+1}$.

Since λ is a partition, we have $\lambda_1 \geq \lambda_2 \geq \lambda_3 \geq \ldots$. Thus, $\lambda_{k+1} \geq \lambda_{a'}$ (since $k+1 \leq a'$). Thus, $\mu_a \geq \lambda_{k+1} \geq \lambda_{a'}$, so that $\lambda_{a'} \leq \mu_a$ and thus $b' \leq \lambda_{a'} \leq \mu_a < b = b'$, which is absurd. This contradiction proves that our assumption was wrong, and thus Assertion A is proven.

Every positive integer n satisfies

$$\begin{aligned}
(T \circ \Delta)(h_n) &= T\left(\underbrace{\Delta h_n}_{\substack{=\sum_{i+j=n} h_i \otimes h_j \\ \text{(by Proposition 2.3.6(iii))}}}\right) \\
&\qquad \left(\begin{array}{c}\text{here, we are using the notation } \sum_{i+j=n} h_i \otimes h_j \\ \text{in the same way as explained in Proposition 2.3.6}\end{array}\right) \\
&= T\left(\sum_{i+j=n} h_i \otimes h_j\right) = \sum_{i+j=n} h_j \otimes h_i \qquad \text{(by the definition of the twist map } T\text{)} \\
&= \underbrace{\sum_{j+i=n}}_{=\sum_{i+j=n}} h_i \otimes h_j \qquad \text{(here, we renamed the summation index } (i,j) \text{ as } (j,i)\text{)} \\
&= \sum_{i+j=n} h_i \otimes h_j = \Delta h_n \qquad \text{(by Proposition 2.3.6(iii))} \\
&= \Delta(h_n).
\end{aligned}$$

In other words, for every positive integer n, the two maps $T \circ \Delta$ and Δ are equal to each other on the element h_n. In other words, the two maps $T \circ \Delta$ and Δ are equal to each other on the set $\{h_1, h_2, h_3, ...\}$. Hence, the two maps $T \circ \Delta$ and Δ are equal to each other on a generating set of the $\mathbf{k}$-algebra Λ (since the set $\{h_1, h_2, h_3, ...\}$ is a generating set of the $\mathbf{k}$-algebra Λ). Since these two maps $T \circ \Delta$ and Δ are $\mathbf{k}$-algebra homomorphisms, this shows that the two maps $T \circ \Delta$ and Δ must be identical (because if two $\mathbf{k}$-algebra homomorphisms with the same domain and the same target are equal to each other on a generating set of their domain, then these two homomorphisms must be identical). In other words, $T \circ \Delta = \Delta$. Hence, the diagram (13.51.1) commutes. As we know, this shows that the Hopf algebra Λ is cocommutative. This solves Exercise 2.3.7(a).

(b) Let λ and ν be two partitions. We have shown above that $T \circ \Delta = \Delta$. Hence, $\Delta = T \circ \Delta$. Applying both sides of this equality to $s_{\lambda/\nu}$, we obtain

$$\begin{aligned}
\Delta s_{\lambda/\nu} = (T \circ \Delta)(s_{\lambda/\nu}) &= T\left(\underbrace{\Delta s_{\lambda/\nu}}_{\substack{=\sum_{\substack{\mu \in \operatorname{Par}: \\ \nu \subseteq \mu \subseteq \lambda}} s_{\mu/\nu} \otimes s_{\lambda/\mu} \\ \text{(by Proposition 2.3.6(v))}}}\right) = T\left(\sum_{\substack{\mu \in \operatorname{Par}: \\ \nu \subseteq \mu \subseteq \lambda}} s_{\mu/\nu} \otimes s_{\lambda/\mu}\right) \\
&= \sum_{\substack{\mu \in \operatorname{Par}: \\ \nu \subseteq \mu \subseteq \lambda}} s_{\lambda/\mu} \otimes s_{\mu/\nu} \qquad \text{(by the definition of the twist map } T\text{)}.
\end{aligned}$$

This solves Exercise 2.3.7(b).

13.52. **Solution to Exercise 2.3.8.** *Solution to Exercise 2.3.8.* (a) Whenever $\alpha = (\alpha_1, \alpha_2, \alpha_3, ...)$ is a weak composition satisfying ($\alpha_i = 0$ for every $i > n$), the monomial $\mathbf{x}^\alpha$ is a monomial in $\mathbf{k}[x_1, x_2, ..., x_n]$. This will be often used in the following.

Recall that $s_{\lambda/\mu}$ is defined as $\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)}$. Now, $s_{\lambda/\mu}(x_1, x_2, \ldots, x_n)$ is the result of substituting $x_1, x_2, ..., x_n, 0, 0, 0, ...$ for $x_1, x_2, x_3, ...$ in $s_{\lambda/\mu}$. This substitution has the following effect on any given monomial $\mathbf{x}^\alpha$:

- if none of the indeterminates $x_{n+1}, x_{n+2}, x_{n+3}, ...$ occur in this monomial $\mathbf{x}^{\alpha}$, then the monomial $\mathbf{x}^{\alpha}$ stays fixed;
- otherwise, the monomial $\mathbf{x}^{\alpha}$ goes to 0.

Hence, the effect of this substitution on the power series $s_{\lambda/\mu} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)}$ is that:

- every addend in the sum $\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\operatorname{cont}(T)}$ for which none of the indeterminates $x_{n+1}, x_{n+2}, x_{n+3}, ...$ occur in the monomial $\mathbf{x}^{\operatorname{cont}(T)}$ stays fixed;
- all other addends go to 0.

The result of the substitution is therefore $\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu; \\ \text{none of the indeterminates } x_{n+1}, x_{n+2}, x_{n+3}, ... \\ \text{occur in the monomial } \mathbf{x}^{\operatorname{cont}(T)}}} \mathbf{x}^{\operatorname{cont}(T)}$. We thus have

$$s_{\lambda/\mu}(x_1, x_2, \ldots, x_n) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu; \\ \text{none of the indeterminates } x_{n+1}, x_{n+2}, x_{n+3}, ... \\ \text{occur in the monomial } \mathbf{x}^{\operatorname{cont}(T)}}} \mathbf{x}^{\operatorname{cont}(T)}.$$

But this rewrites as

$$s_{\lambda/\mu}(x_1, x_2, \ldots, x_n) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,...,n\}}} \mathbf{x}^{\operatorname{cont}(T)}$$

(because for a column-strict tableau T, saying that none of the indeterminates $x_{n+1}, x_{n+2}, x_{n+3}, ...$ occur in the monomial $\mathbf{x}^{\operatorname{cont}(T)}$ is equivalent to saying that all entries of T belong to $\{1, 2, ..., n\}$). This solves Exercise 2.3.8(a).

(b) Let λ be a partition having more than n parts. We have to prove that $s_{\lambda}(x_1, x_2, \ldots, x_n) = 0$. Since

$$\underbrace{s_{\lambda}}_{= s_{\lambda/\varnothing}}(x_1, x_2, \ldots, x_n) = s_{\lambda/\varnothing}(x_1, x_2, \ldots, x_n) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\varnothing; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,...,n\}}} \mathbf{x}^{\operatorname{cont}(T)}$$

(by Exercise 2.3.8(a), applied to $\mu = \varnothing$), this goal will clearly be achieved if we can show that the sum $\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\varnothing; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,...,n\}}} \mathbf{x}^{\operatorname{cont}(T)}$ is empty, i.e., that there exists no column-strict tableau T of shape $\lambda/\varnothing$ such that all entries of T belong to $\{1, 2, ..., n\}$.

Assume the contrary. Thus, there exists a column-strict tableau T of shape $\lambda/\varnothing$ such that all entries of T belong to $\{1, 2, ..., n\}$. This tableau has more than n rows (since the partition λ has more than n parts), and thus the first column of this tableau must have more than n entries. These entries must be strictly increasing top-to-bottom (since the entries of a column-strict tableau strictly increase top-to-bottom along columns) and hence be distinct, but at the same time (like all entries of T) they must belong to $\{1, 2, ..., n\}$. So we have found more than n entries which are distinct and belong to $\{1, 2, ..., n\}$. This contradicts the fact that the set $\{1, 2, ..., n\}$ does not have more than n distinct elements. This contradiction concludes our proof, and Exercise 2.3.8(b) is solved.

13.53. **Solution to Exercise 2.4.4.** *Solution to Exercise 2.4.4.*

Proof of Proposition 2.4.3. The map ω is precisely the $\mathbf{k}$-algebra homomorphism ω defined in the proof of Proposition 2.4.1. Thus, in particular, ω is a $\mathbf{k}$-algebra homomorphism; hence, $\omega(1) = 1$ and $\omega(0) = 0$.

(a) Let $n \in \mathbb{Z}$. We must prove that $\omega(e_n) = h_n$.

If n is a positive integer, then this follows immediately from the definition of ω. Thus, for the rest of the proof of $\omega\left(e_n\right)=h_n$, we can WLOG assume that n is not a positive integer. Assume this.

From $e_0=1$, we obtain $\omega\left(e_0\right)=\omega\left(1\right)=1=h_0$ (since $h_0=1$). Hence, $\omega\left(e_n\right)=h_n$ holds for $n=0$. Thus, for the rest of the proof of $\omega\left(e_n\right)=h_n$, we can WLOG assume that we don't have $n=0$. Assume this.

Now, n is a negative integer (since n is not a positive integer, and since we don't have $n=0$). This yields $h_n=0$ and $e_n=0$. Now, $\omega\left(\underbrace{e_n}_{=0}\right)=\omega\left(0\right)=0=h_n$. This proves $\omega\left(e_n\right)=h_n$. This proves Proposition 2.4.3(a).

(b) The proof of Proposition 2.4.3(b) is completely analogous to the proof of Proposition 2.4.3(a) given above, except that e_n and h_n trade places (and that we need to use (2.4.9) instead of the definition of ω).

(d) In the proof of Proposition 2.4.1, we have shown that ω is an involution and a $\mathbf{k}$-algebra automorphism of Λ. This proves Proposition 2.4.3(d).

(e) Proposition 1.4.10 (applied to $A=\Lambda$) shows that the antipode S of Λ is a $\mathbf{k}$-algebra anti-endomorphism. In other words, S is a $\mathbf{k}$-algebra anti-homomorphism from Λ to Λ. But Exercise 1.5.8(a) (applied to $A=\Lambda$ and $B=\Lambda$) shows that the $\mathbf{k}$-algebra anti-homomorphisms from Λ to Λ are the same as the $\mathbf{k}$-algebra homomorphisms from Λ to Λ (since the $\mathbf{k}$-algebra Λ is commutative). Hence, S is a $\mathbf{k}$-algebra homomorphism from Λ to Λ (since S is a $\mathbf{k}$-algebra anti-homomorphism from Λ to Λ).

Recall that Λ is a graded $\mathbf{k}$-bialgebra. Let $q=-1\in\mathbf{k}$. Consider the $\mathbf{k}$-linear map $D_q:\Lambda\to\Lambda$ constructed in Exercise 1.3.24 (applied to $A=\Lambda$). From Exercise 1.3.24 (applied to $A=\Lambda$), we know that this map D_q is a $\mathbf{k}$-bialgebra homomorphism; thus, in particular, D_q is a $\mathbf{k}$-algebra homomorphism. The definition of D_q shows that

$$D_q\left(a\right)=q^n a \qquad \text{for each } n\in\mathbb{N} \text{ and each } a\in\Lambda_n. \tag{13.53.1}$$

Now, the map $\omega\circ D_q:\Lambda\to\Lambda$ is a $\mathbf{k}$-algebra homomorphism (since it is the composition of the two $\mathbf{k}$-algebra homomorphisms ω and D_q).

Let n be a positive integer. Then, $\omega\left(e_n\right)=h_n$ (by the definition of ω). But $e_n\in\Lambda_n$; hence, (13.53.1) (applied to $a=e_n$) yields $D_q\left(e_n\right)=q^n e_n=\left(-1\right)^n e_n$ (since $q=-1$). Now,

$$\begin{aligned}\left(\omega\circ D_q\right)\left(e_n\right)&=\omega\left(\underbrace{D_q\left(e_n\right)}_{=\left(-1\right)^n e_n}\right)=\omega\left(\left(-1\right)^n e_n\right)=\left(-1\right)^n\underbrace{\omega\left(e_n\right)}_{=h_n} \qquad \text{(since the map } \omega \text{ is } \mathbf{k}\text{-linear)}\\&=\left(-1\right)^n h_n.\end{aligned}$$

Comparing this with

$$S\left(e_n\right)=\left(-1\right)^n h_n \qquad \text{(by Proposition 2.4.1(ii))},$$

we obtain $\left(\omega\circ D_q\right)\left(e_n\right)=S\left(e_n\right)$.

Now, forget that we fixed n. We thus have shown that $\left(\omega\circ D_q\right)\left(e_n\right)=S\left(e_n\right)$ for each positive integer n. In other words, the two $\mathbf{k}$-algebra homomorphisms $\omega\circ D_q$ and S (from Λ to Λ) agree on each element of the family $\left\{e_n\right\}_{n\geq 1}$ of elements of Λ.

But Proposition 2.4.1 tells us that the family $\left\{e_n\right\}_{n\geq 1}$ generates the $\mathbf{k}$-algebra Λ. Thus, if two $\mathbf{k}$-algebra homomorphisms from Λ agree on each element of this family $\left\{e_n\right\}_{n\geq 1}$, then these two homomorphisms must be equal. Hence, the two $\mathbf{k}$-algebra homomorphisms $\omega\circ D_q$ and S must be equal (since they agree on each element of this family $\left\{e_n\right\}_{n\geq 1}$). In other words, we have $\omega\circ D_q=S$.

Now, let $n \in \mathbb{N}$ and let $f \in \Lambda_n$. We must show that $S(f) = (-1)^n \omega(f)$. And indeed, we have $\underbrace{(\omega \circ D_q)}_{=S}(f) = S(f)$, so that

$$\begin{aligned} S(f) = (\omega \circ D_q)(f) = \omega\left(\underbrace{D_q(f)}_{\substack{=q^n f \\ \text{(by (13.53.1), applied to } a=f)}}\right) = \omega(q^n f) \\ = q^n \omega(f) \qquad \text{(since the map } \omega \text{ is } \mathbf{k}\text{-linear)} \\ = (-1)^n \omega(f) \qquad \text{(since } q = -1). \end{aligned}$$

This proves Proposition 2.4.3(e).

(c) Let n be a positive integer. Proposition 2.4.1(i) yields $S(p_n) = -p_n$. But (2.4.11) (applied to $f = p_n$) yields $S(p_n) = (-1)^n \omega(p_n)$ (since $p_n \in \Lambda_n$). Comparing these two equalities yields $(-1)^n \omega(p_n) = -p_n$, and this quickly rewrites as $\omega(p_n) = (-1)^{n-1} p_n$. This proves Proposition 2.4.3(c).

(f) To show that ω is a coalgebra homomorphism, it suffices to check that $(\omega \otimes \omega) \circ \Delta = \Delta \circ \omega$ and $\epsilon = \epsilon \circ \omega$.

Let us first prove that $(\omega \otimes \omega) \circ \Delta = \Delta \circ \omega$. Indeed, both sides of this equality being $\mathbf{k}$-algebra homomorphisms, it only needs to be checked on the algebra generators h_n of Λ (indeed, we know from Proposition 2.4.1 that the family $\{h_n\}_{n \geq 1}$ generates the $\mathbf{k}$-algebra Λ). On these generators this is easy to check: Comparing

$$\begin{aligned} ((\omega \otimes \omega) \circ \Delta)(h_n) = (\omega \otimes \omega)(\Delta(h_n)) = (\omega \otimes \omega)\left(\sum_{i+j=n} h_i \otimes h_j\right) \qquad \text{(by Proposition 2.3.6(iii))} \\ = \sum_{i+j=n} \underbrace{\omega(h_i)}_{\substack{=e_i \\ \text{(by Proposition 2.4.3(b))}}} \otimes \underbrace{\omega(h_j)}_{\substack{=e_j \\ \text{(by Proposition 2.4.3(b))}}} = \sum_{i+j=n} e_i \otimes e_j \end{aligned}$$

and

$$(\Delta \circ \omega)(h_n) = \Delta\left(\underbrace{\omega(h_n)}_{\substack{=e_n \\ \text{(by Proposition 2.4.3(b))}}}\right) = \Delta(e_n) = \sum_{i+j=n} e_i \otimes e_j \qquad \text{(by Proposition 2.3.6(ii))}$$

shows that $((\omega \otimes \omega) \circ \Delta)(h_n) = (\Delta \circ \omega)(h_n)$ for all $n \geq 1$. So we obtain $(\omega \otimes \omega) \circ \Delta = \Delta \circ \omega$. The equality $\epsilon = \epsilon \circ \omega$ is even easier to check. Thus, ω is an algebra and coalgebra morphism, thus a bialgebra morphism, thus a Hopf morphism by Corollary 1.4.27. Since ω is invertible (by part (d)), we conclude that ω is a Hopf algebra automorphism. This proves Proposition 2.4.3(f).

(g) Part (g) of Proposition 2.4.3 can be proved in the same way as we proved part (f) above, with the following three differences:

- We need to know that S is a $\mathbf{k}$-algebra homomorphism. (This was shown during the proof of Proposition 2.4.3(e) above.)
- We need to know that S is invertible. (This can be concluded from Corollary 1.4.12, or from the fact that ω is invertible using Proposition 2.4.3(e).)
- Instead of the formula $\omega(h_n) = e_n$ we now need to use the formula $S(h_n) = (-1)^n e_n$ (which is Proposition 2.4.1(iii)), and thus we incur some signs in the computation.

[*Remark:* Let us sketch alternative approaches to proving parts (f) and (g) of Proposition 2.4.3:

Alternative proof of Proposition 2.4.3(g) (sketched): We have already seen (during the proof of Proposition 2.4.3(e) above) that S is a $\mathbf{k}$-algebra homomorphism. Corollary 1.4.12 (applied to $S = \Lambda$) yields that S is an involution; thus, S is invertible. Moreover, the Hopf algebra Λ is cocommutative (by Exercise 2.3.7(a)). But Exercise 1.4.28 (applied to $A = \Lambda$) yields that the antipode S of Λ is a $\mathbf{k}$-coalgebra anti-endomorphism of Λ. In other words, S is a $\mathbf{k}$-coalgebra anti-homomorphism from Λ to Λ. But Exercise 1.5.8(b) (applied to $A = \Lambda$ and $B = \Lambda$) shows that the $\mathbf{k}$-coalgebra anti-homomorphisms from Λ to Λ are the same as the

k-coalgebra homomorphisms from Λ to Λ (since the **k**-coalgebra Λ is cocommutative). Hence, S is a **k**-coalgebra homomorphism from Λ to Λ (since S is a **k**-coalgebra anti-homomorphism from Λ to Λ). We now know that S is a **k**-algebra homomorphism and a **k**-coalgebra homomorphism at the same time. Hence, S is a **k**-bialgebra homomorphism, therefore a Hopf morphism (by Corollary 1.4.27), and thus a Hopf algebra automorphism (since S is invertible). This proves Proposition 2.4.3(g) again.

Alternative proof of Proposition 2.4.3(f) (sketched): Proposition 2.4.3(g) shows that S is a Hopf algebra automorphism. Define q and D_q as in the proof of Proposition 2.4.3(e) above. It is easy to see that D_q is an involution; thus, D_q is invertible. But D_q is a **k**-bialgebra homomorphism (as we have seen in the proof of Proposition 2.4.3(e) above), therefore a Hopf morphism (by Corollary 1.4.27), and thus a Hopf algebra automorphism (since D_q is invertible). Now, recall that $\omega \circ D_q = S$ (as we have seen in the proof of Proposition 2.4.3(e) above). Hence, $\omega = S \circ (D_q)^{-1}$ (since D_q is invertible). This shows that ω is a Hopf algebra automorphism (since both S and D_q are Hopf algebra automorphisms). This proves Proposition 2.4.3(f) again.]

(h) Let λ be a partition.

We can easily obtain (2.4.14) by multiplicativity:

[*Proof of* (2.4.14)*:* Let ℓ be the length $\ell(\lambda)$ of the partition λ. Then, p_λ is defined as $p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell}$, and thus we have

$$\begin{aligned}
\omega(p_\lambda) &= \omega(p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell}) = \omega(p_{\lambda_1})\,\omega(p_{\lambda_2}) \cdots \omega(p_{\lambda_\ell}) && \text{(since } \omega \text{ is a } \mathbf{k}\text{-algebra homomorphism)} \\
&= (-1)^{\lambda_1 - 1} p_{\lambda_1} \cdot (-1)^{\lambda_2 - 1} p_{\lambda_2} \cdots (-1)^{\lambda_\ell - 1} p_{\lambda_\ell} && \text{(by Proposition 2.4.3(c))} \\
&= \underbrace{(-1)^{(\lambda_1 + \lambda_2 + \cdots + \lambda_\ell) - \ell}}_{\substack{= (-1)^{|\lambda| - \ell(\lambda)} \\ \text{(since } \lambda_1 + \lambda_2 + \cdots + \lambda_\ell = |\lambda| \\ \text{and } \ell = \ell(\lambda))}} \underbrace{p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell}}_{= p_\lambda} = (-1)^{|\lambda| - \ell(\lambda)} p_\lambda.
\end{aligned}$$

This proves (2.4.14).]

A similar argument (but using Proposition 2.4.3(b) instead of Proposition 2.4.3(c)) proves (2.4.12). Finally, a similar argument (but using Proposition 2.4.3(a) instead of Proposition 2.4.3(c)) proves (2.4.13).

We have now proved all three equalities (2.4.12), (2.4.13) and (2.4.14). Thus, Proposition 2.4.3(h) is proved.

(i) Proposition 2.4.3(d) yields that the map ω is a **k**-algebra automorphism of Λ and an involution. Thus, ω is an involution. In other words, ω is invertible, and the inverse of ω is ω itself.

We know that Λ is a connected graded bialgebra. Thus, Proposition 1.4.16 (applied to $A = \Lambda$) yields that Λ has a unique antipode S, which is a graded map $\Lambda \xrightarrow{S} \Lambda$, endowing it with a Hopf structure. Thus, in particular, the antipode S of Λ is a graded map. In other words,

$$S(\Lambda_n) \subset \Lambda_n \qquad \text{for each } n \in \mathbb{N}. \tag{13.53.2}$$

Now, let $n \in \mathbb{N}$. Let $f \in \Lambda_n$. Then, Proposition 2.4.3(e) yields $S(f) = (-1)^n \omega(f)$. Hence,

$$(-1)^n \underbrace{S(f)}_{= (-1)^n \omega(f)} = \underbrace{(-1)^n (-1)^n}_{\substack{= (-1)^{n+n} = (-1)^{2n} = 1 \\ \text{(since } 2n \text{ is even)}}} \omega(f) = \omega(f),$$

so that $\omega(f) = (-1)^n S\left(\underbrace{f}_{\in \Lambda_n}\right) \in (-1)^n \underbrace{S(\Lambda_n)}_{\substack{\subset \Lambda_n \\ \text{(by (13.53.2))}}} \subset (-1)^n \Lambda_n \subset \Lambda_n$ (since Λ_n is a **k**-module).

Forget that we fixed f. We thus have proved that $\omega(f) \in \Lambda_n$ for each $f \in \Lambda_n$. In other words, $\omega(\Lambda_n) \subset \Lambda_n$.

Forget that we fixed n. We thus have shown that $\omega(\Lambda_n) \subset \Lambda_n$ for each $n \in \mathbb{N}$. Hence, the **k**-linear map $\omega : \Lambda \to \Lambda$ is graded. In other words, the inverse of ω is graded (since the inverse of ω is ω itself).

Now, we know that the **k**-linear map ω is graded, and its inverse is also graded. In other words, the **k**-linear map ω is an isomorphism of graded **k**-modules. This proves Proposition 2.4.3(i).

(j) From (2.4.13), we know that $\omega(e_\lambda) = h_\lambda$ for each partition λ. In other words, $\omega(e_\lambda) = h_\lambda$ for each $\lambda \in \operatorname{Par}$. In other words, $(\omega(e_\lambda))_{\lambda \in \operatorname{Par}} = (h_\lambda)_{\lambda \in \operatorname{Par}}$.

Proposition 2.2.10 says (among other things) that the family $\{e_\lambda\}$, as λ runs through all partitions, is a graded basis of the graded $\mathbf{k}$-module Λ. In other words, the family $(e_\lambda)_{\lambda\in\operatorname{Par}}$ is a graded basis of the graded $\mathbf{k}$-module Λ. On the other hand, Proposition 2.4.3(i) shows that the map ω is an isomorphism of graded $\mathbf{k}$-modules.

Now, recall the following well-known fact: If V and W are two graded $\mathbf{k}$-modules, and if $f : V \to W$ is an isomorphism of graded $\mathbf{k}$-modules, then f sends any graded basis of V to a graded basis of W. In other words, if V and W are two graded $\mathbf{k}$-modules, and if $f : V \to W$ is an isomorphism of graded $\mathbf{k}$-modules, and if $(v_i)_{i\in I}$ is a graded basis of V, then $(f(v_i))_{i\in I}$ is a graded basis of W.

We can apply this fact to $V = \Lambda$, $W = \Lambda$, $f = \omega$, $I = \operatorname{Par}$ and $(v_i)_{i\in I} = (e_\lambda)_{\lambda\in\operatorname{Par}}$ (since we know that $\omega : \Lambda \to \Lambda$ is an isomorphism of graded $\mathbf{k}$-modules, and since we know that the family $(e_\lambda)_{\lambda\in\operatorname{Par}}$ is a graded basis of Λ). We thus conclude that $(\omega(e_\lambda))_{\lambda\in\operatorname{Par}}$ is a graded basis of Λ. In other words, the family $(h_\lambda)_{\lambda\in\operatorname{Par}}$ is a graded basis of Λ (since $(\omega(e_\lambda))_{\lambda\in\operatorname{Par}} = (h_\lambda)_{\lambda\in\operatorname{Par}}$). This proves Proposition 2.4.3(j). □

We have now proved Proposition 2.4.3; thus, Exercise 2.4.4 is solved.

13.54. **Solution to Exercise 2.5.5.** *Solution to Exercise 2.5.5.* Recall that for each partition λ,

$$\text{the element } q_\lambda \in \Lambda \text{ is homogeneous of degree } |\lambda| . \tag{13.54.1}$$

(a) Let $(a_\lambda)_{\lambda\in\operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ and $(b_\lambda)_{\lambda\in\operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ be two families satisfying (2.5.3) in $\mathbf{k}[[\mathbf{x}]]$. We must prove that $(a_\lambda)_{\lambda\in\operatorname{Par}} = (b_\lambda)_{\lambda\in\operatorname{Par}}$.

Fix $n \in \mathbb{N}$. Consider the $\mathbf{k}$-linear map $\pi_n : \mathbf{k}[[\mathbf{x}]] \to \mathbf{k}[[\mathbf{x}]]$ that sends each power series $f \in \mathbf{k}[[\mathbf{x}]]$ to its homogeneous component of degree n. Thus, π_n has the following properties:

- If $f \in \mathbf{k}[[\mathbf{x}]]$ is a power series that is homogeneous of degree n, then
$$\pi_n(f) = f. \tag{13.54.2}$$
- If $f \in \mathbf{k}[[\mathbf{x}]]$ is a power series that is homogeneous of degree $\neq n$, then
$$\pi_n(f) = 0. \tag{13.54.3}$$
- The map π_n is $\mathbf{k}$-linear and continuous (with respect to the topology on $\mathbf{k}[[\mathbf{x}]]$).

Hence, each $\lambda \in \operatorname{Par}$ satisfying $|\lambda| = n$ satisfies

$$\pi_n(q_\lambda(\mathbf{x})) = q_\lambda(\mathbf{x}) \tag{13.54.4}$$

[576]. Furthermore, each $\lambda \in \operatorname{Par}$ satisfying $|\lambda| \neq n$ satisfies

$$\pi_n(q_\lambda(\mathbf{x})) = 0 \tag{13.54.5}$$

[577].

But the map π_n is $\mathbf{k}$-linear and continuous. Thus, it respects infinite sums. Hence,

$$\pi_n\left(\sum_{\lambda\in\operatorname{Par}} a_\lambda q_\lambda(\mathbf{x})\right) = \sum_{\lambda\in\operatorname{Par}} a_\lambda \pi_n(q_\lambda(\mathbf{x})) = \sum_{\substack{\lambda\in\operatorname{Par};\\ |\lambda|=n}} a_\lambda \underbrace{\pi_\lambda(q_\lambda(\mathbf{x}))}_{\substack{=q_\lambda(\mathbf{x})\\ \text{(by (13.54.4))}}} + \sum_{\substack{\lambda\in\operatorname{Par};\\ |\lambda|\neq n}} a_\lambda \underbrace{\pi_\lambda(q_\lambda(\mathbf{x}))}_{\substack{=0\\ \text{(by (13.54.5))}}}$$
$$= \sum_{\substack{\lambda\in\operatorname{Par};\\ |\lambda|=n}} a_\lambda q_\lambda(\mathbf{x}) + \underbrace{\sum_{\substack{\lambda\in\operatorname{Par};\\ |\lambda|\neq n}} a_\lambda 0}_{=0} = \sum_{\substack{\lambda\in\operatorname{Par};\\ |\lambda|=n}} a_\lambda q_\lambda(\mathbf{x}) . \tag{13.54.6}$$

[576] *Proof of (13.54.4):* Let $\lambda \in \operatorname{Par}$ be such that $|\lambda| = n$. From (13.54.1), we know that the element $q_\lambda \in \Lambda$ is homogeneous of degree $|\lambda|$. Thus, the power series $q_\lambda(\mathbf{x})$ is homogeneous of degree $|\lambda| = n$. Hence, (13.54.2) (applied to $f = q_\lambda(\mathbf{x})$) yields $\pi_n(q_\lambda(\mathbf{x})) = q_\lambda(\mathbf{x})$. This proves (13.54.4).

[577] *Proof of (13.54.5):* Let $\lambda \in \operatorname{Par}$ be such that $|\lambda| \neq n$. From (13.54.1), we know that the element $q_\lambda \in \Lambda$ is homogeneous of degree $|\lambda|$. Thus, the power series $q_\lambda(\mathbf{x})$ is homogeneous of degree $|\lambda| \neq n$. Hence, (13.54.3) (applied to $f = q_\lambda(\mathbf{x})$) yields $\pi_n(q_\lambda(\mathbf{x})) = 0$. This proves (13.54.5).

The same argument (applied to the family $(b_\lambda)_{\lambda\in\text{Par}}$ instead of $(a_\lambda)_{\lambda\in\text{Par}}$) yields

$$\pi_n\left(\sum_{\lambda\in\text{Par}} b_\lambda q_\lambda(\mathbf{x})\right) = \sum_{\substack{\lambda\in\text{Par};\\ |\lambda|=n}} b_\lambda q_\lambda(\mathbf{x}). \tag{13.54.7}$$

Now, applying the map π_n to both sides of the equality (2.5.3), we obtain

$$\pi_n\left(\sum_{\lambda\in\text{Par}} a_\lambda q_\lambda(\mathbf{x})\right) = \pi_n\left(\sum_{\lambda\in\text{Par}} b_\lambda q_\lambda(\mathbf{x})\right) = \sum_{\substack{\lambda\in\text{Par};\\ |\lambda|=n}} b_\lambda q_\lambda(\mathbf{x}).$$

Comparing this with (13.54.6), we obtain

$$\sum_{\substack{\lambda\in\text{Par};\\ |\lambda|=n}} a_\lambda q_\lambda(\mathbf{x}) = \sum_{\substack{\lambda\in\text{Par};\\ |\lambda|=n}} b_\lambda q_\lambda(\mathbf{x}). \tag{13.54.8}$$

Notice that both sums appearing in this equality are finite (since there are only finitely many $\lambda \in \text{Par}$ satisfying $|\lambda| = n$). Since the family $(q_\lambda(\mathbf{x}))_{\lambda\in\text{Par};\ |\lambda|=n}$ is $\mathbf{k}$-linearly independent[578], we can thus conclude from (13.54.8) that

$$a_\lambda = b_\lambda \qquad \text{for each } \lambda\in\text{Par} \text{ satisfying } |\lambda| = n. \tag{13.54.9}$$

Now, forget that we fixed n. We thus have proven (13.54.9) for each $n \in \mathbb{N}$.

Now, let $\lambda \in \text{Par}$ be arbitrary. Then, $|\lambda| \in \mathbb{N}$. Hence, (13.54.9) (applied to $n = |\lambda|$) yields $a_\lambda = b_\lambda$.

Now, forget that we fixed λ. We thus have proven that $a_\lambda = b_\lambda$ for each $\lambda \in \text{Par}$. In other words, $(a_\lambda)_{\lambda\in\text{Par}} = (b_\lambda)_{\lambda\in\text{Par}}$. This solves Exercise 2.5.5 (a).

(c) We first go afield. Recall that $(m_\lambda)_{\lambda\in\text{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, the family $(m_\mu \otimes m_\nu \otimes m_\lambda)_{(\mu,\nu,\lambda)\in\text{Par}^3}$ is a basis of the $\mathbf{k}$-module $\Lambda\otimes\Lambda\otimes\Lambda$.

On the other hand, $(q_\lambda)_{\lambda\in\text{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, the family $(q_\mu \otimes q_\nu \otimes q_\lambda)_{(\mu,\nu,\lambda)\in\text{Par}^3}$ is a basis of the $\mathbf{k}$-module $\Lambda\otimes\Lambda\otimes\Lambda$.

We shall now show that the family $(m_\mu(\mathbf{x})\, m_\nu(\mathbf{y})\, m_\lambda(\mathbf{z}))_{(\mu,\nu,\lambda)\in\text{Par}^3}$ of elements of $\mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$ is $\mathbf{k}$-linearly independent.

If $\mathfrak{m}$ is a monomial, and if f is a power series, then we let $[\mathfrak{m}]\, f$ denote the coefficient of $\mathfrak{m}$ in f.

Any $\tau \in \text{Par}$ and $\lambda \in \text{Par}$ satisfy

$$[\mathbf{x}^\tau]\,(m_\lambda(\mathbf{x})) = \delta_{\tau,\lambda} \tag{13.54.10}$$

[579].

For any three partitions $\alpha, \beta, \gamma \in \text{Par}$ and any three partitions $\mu, \nu, \lambda \in \text{Par}$, we have

$$\left[\mathbf{x}^\alpha \mathbf{y}^\beta \mathbf{z}^\gamma\right](m_\mu(\mathbf{x})\, m_\nu(\mathbf{y})\, m_\lambda(\mathbf{z})) = \delta_{(\alpha,\beta,\gamma),(\mu,\nu,\lambda)} \tag{13.54.12}$$

[578] *Proof.* The family $\left(\underbrace{q_\lambda(\mathbf{x})}_{=q_\lambda}\right)_{\lambda\in\text{Par}} = (q_\lambda)_{\lambda\in\text{Par}}$ is a basis of the $\mathbf{k}$-module Λ, and thus is $\mathbf{k}$-linearly independent. Hence, the family $(q_\lambda(\mathbf{x}))_{\lambda\in\text{Par};\ |\lambda|=n}$ is $\mathbf{k}$-linearly independent as well (since it is a subfamily of this family $(q_\lambda(\mathbf{x}))_{\lambda\in\text{Par}}$).

[579] *Proof of (13.54.10):* Let $\tau \in \text{Par}$ and $\lambda \in \text{Par}$. The set $\mathfrak{S}_{(\infty)}\lambda$ clearly contains λ, since $\lambda = \underbrace{\text{id}}_{\in\mathfrak{S}_{(\infty)}} \cdot\lambda \in \mathfrak{S}_{(\infty)}\lambda$. Moreover, each $\alpha \in \mathfrak{S}_{(\infty)}\lambda$ satisfying $\alpha \neq \lambda$ must satisfy

$$\delta_{\tau,\alpha} = 0. \tag{13.54.11}$$

[*Proof of (13.54.11):* Let $\alpha \in \mathfrak{S}_{(\infty)}\lambda$ be such that $\alpha \neq \lambda$.

Assume (for the sake of contradiction) that $\tau = \alpha$. Then, $\alpha = \tau \in \text{Par}$. Hence, the sequence α is nonincreasing. But the sequence λ is also nonincreasing (since $\lambda \in \text{Par}$).

From $\alpha \in \mathfrak{S}_{(\infty)}\lambda$, we conclude that α is a rearrangement of the partition λ. But λ is also a rearrangement of λ. However, there is only one nonincreasing rearrangement of λ. In other words, if μ and ν are two nonincreasing rearrangements of λ, then $\mu = \nu$. Applying this to $\mu = \alpha$ and $\nu = \lambda$, we conclude that $\alpha = \lambda$ (since both α and λ are nonincreasing rearrangements of λ). This contradicts $\alpha \neq \lambda$.

This contradiction shows that our assumption (that $\tau = \alpha$) was false. Hence, we have $\tau \neq \alpha$. Thus, $\delta_{\tau,\alpha} = 0$. This proves (13.54.11).]

[580].

Hence, if $(c_{\mu,\nu,\lambda})_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} \in \mathbf{k}^{\operatorname{Par}^3}$ is a family of elements of $\mathbf{k}$ satisfying

$$\sum_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} c_{\mu,\nu,\lambda} m_\mu(\mathbf{x}) m_\nu(\mathbf{y}) m_\lambda(\mathbf{z}) = 0, \tag{13.54.13}$$

then $(c_{\mu,\nu,\lambda})_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} = (0)_{(\mu,\nu,\lambda)\in\operatorname{Par}^3}$ [581]. Thus, the family $(m_\mu(\mathbf{x}) m_\nu(\mathbf{y}) m_\lambda(\mathbf{z}))_{(\mu,\nu,\lambda)\in\operatorname{Par}^3}$ of elements of $\mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$ is $\mathbf{k}$-linearly independent.

Hence, the $\mathbf{k}$-linear map

$$\Lambda\otimes\Lambda\otimes\Lambda \to \mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]], \qquad f\otimes g\otimes h \mapsto f(\mathbf{x})\,g(\mathbf{y})\,h(\mathbf{z})$$

We have $m_\lambda(\mathbf{x}) = m_\lambda = \sum_{\alpha\in\mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^\alpha$ (by (2.1.1)). Thus,

$$\begin{aligned}
[\mathbf{x}^\tau]\left(\underbrace{m_\lambda(\mathbf{x})}_{=\sum_{\alpha\in\mathfrak{S}_{(\infty)}\lambda}\mathbf{x}^\alpha}\right) &= [\mathbf{x}^\tau]\left(\sum_{\alpha\in\mathfrak{S}_{(\infty)}\lambda}\mathbf{x}^\alpha\right) = \sum_{\alpha\in\mathfrak{S}_{(\infty)}\lambda}\underbrace{[\mathbf{x}^\tau](\mathbf{x}^\alpha)}_{=\delta_{\tau,\alpha}} = \sum_{\alpha\in\mathfrak{S}_{(\infty)}\lambda}\delta_{\tau,\alpha}\\
&= \delta_{\tau,\lambda} + \sum_{\substack{\alpha\in\mathfrak{S}_{(\infty)}\lambda;\\ \alpha\neq\lambda}} \underbrace{\delta_{\tau,\alpha}}_{\substack{=0\\ \text{(by (13.54.11))}}}\\
&\qquad\left(\begin{array}{c}\text{here, we have split off the addend for } \alpha=\lambda \text{ from}\\ \text{the sum (since } \lambda\in\mathfrak{S}_{(\infty)}\lambda)\end{array}\right)\\
&= \delta_{\tau,\lambda} + \underbrace{\sum_{\substack{\alpha\in\mathfrak{S}_{(\infty)}\lambda;\\ \alpha\neq\lambda}} 0}_{=0} = \delta_{\tau,\lambda}.
\end{aligned}$$

This proves (13.54.10).

[580] *Proof of (13.54.12):* Let $\alpha,\beta,\gamma\in\operatorname{Par}$ be three partitions. Let $\mu,\nu,\lambda\in\operatorname{Par}$ be three partitions. Then, (13.54.10) (applied to α and μ instead of τ and λ) yields $[\mathbf{x}^\alpha](m_\mu(\mathbf{x})) = \delta_{\alpha,\mu}$. Also, (13.54.10) (applied to β and ν instead of τ and λ) yields $[\mathbf{x}^\beta](m_\nu(\mathbf{x})) = \delta_{\beta,\nu}$. Renaming the indeterminates $\mathbf{x}$ as $\mathbf{y}$ in this fact, we obtain $[\mathbf{y}^\beta](m_\nu(\mathbf{y})) = \delta_{\beta,\nu}$. Finally, (13.54.10) (applied to γ and λ instead of τ and λ) yields $[\mathbf{x}^\gamma](m_\lambda(\mathbf{x})) = \delta_{\gamma,\lambda}$. Renaming the indeterminates $\mathbf{x}$ as $\mathbf{z}$ in this fact, we obtain $[\mathbf{z}^\gamma](m_\lambda(\mathbf{z})) = \delta_{\gamma,\lambda}$. Now,

$$\begin{aligned}
\left[\mathbf{x}^\alpha\mathbf{y}^\beta\mathbf{z}^\gamma\right](m_\mu(\mathbf{x})m_\nu(\mathbf{y})m_\lambda(\mathbf{z})) &= \underbrace{([\mathbf{x}^\alpha](m_\mu(\mathbf{x})))}_{=\delta_{\alpha,\mu}}\cdot\underbrace{\left(\left[\mathbf{y}^\beta\right](m_\nu(\mathbf{y}))\right)}_{=\delta_{\beta,\nu}}\cdot\underbrace{([\mathbf{z}^\gamma](m_\lambda(\mathbf{z})))}_{=\delta_{\gamma,\lambda}}\\
&= \delta_{\alpha,\mu}\cdot\delta_{\beta,\nu}\cdot\delta_{\gamma,\lambda} = \delta_{(\alpha,\beta,\gamma),(\mu,\nu,\lambda)}.
\end{aligned}$$

This proves (13.54.12).

[581] *Proof.* Let $(c_{\mu,\nu,\lambda})_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} \in \mathbf{k}^{\operatorname{Par}^3}$ be a family of elements of $\mathbf{k}$ satisfying (13.54.13). We must show that $(c_{\mu,\nu,\lambda})_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} = (0)_{(\mu,\nu,\lambda)\in\operatorname{Par}^3}$.

Fix any $(\alpha,\beta,\gamma)\in\operatorname{Par}^3$. Then,

$$\begin{aligned}
&\left[\mathbf{x}^\alpha\mathbf{y}^\beta\mathbf{z}^\gamma\right]\left(\sum_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} c_{\mu,\nu,\lambda} m_\mu(\mathbf{x}) m_\nu(\mathbf{y}) m_\lambda(\mathbf{z})\right)\\
&= \sum_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} c_{\mu,\nu,\lambda}\underbrace{\left[\mathbf{x}^\alpha\mathbf{y}^\beta\mathbf{z}^\gamma\right](m_\mu(\mathbf{x})m_\nu(\mathbf{y})m_\lambda(\mathbf{z}))}_{\substack{=\delta_{(\alpha,\beta,\gamma),(\mu,\nu,\lambda)}\\ \text{(by (13.54.12))}}}\\
&= \sum_{(\mu,\nu,\lambda)\in\operatorname{Par}^3} c_{\mu,\nu,\lambda}\delta_{(\alpha,\beta,\gamma),(\mu,\nu,\lambda)}\\
&= c_{\alpha,\beta,\gamma}\underbrace{\delta_{(\alpha,\beta,\gamma),(\alpha,\beta,\gamma)}}_{=1} + \sum_{\substack{(\mu,\nu,\lambda)\in\operatorname{Par}^3;\\ (\mu,\nu,\lambda)\neq(\alpha,\beta,\gamma)}} c_{\mu,\nu,\lambda}\underbrace{\delta_{(\alpha,\beta,\gamma),(\mu,\nu,\lambda)}}_{\substack{=0\\ \text{(since } (\alpha,\beta,\gamma)\neq(\mu,\nu,\lambda))}}\\
&\qquad\text{(here, we have split off the addend for } (\mu,\nu,\lambda)=(\alpha,\beta,\gamma) \text{ from the sum)}\\
&= c_{\alpha,\beta,\gamma} + \underbrace{\sum_{\substack{(\mu,\nu,\lambda)\in\operatorname{Par}^3;\\ (\mu,\nu,\lambda)\neq(\alpha,\beta,\gamma)}} c_{\mu,\nu,\lambda}0}_{=0} = c_{\alpha,\beta,\gamma},
\end{aligned}$$

maps the basis $(m_\mu \otimes m_\nu \otimes m_\lambda)_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$ of $\Lambda \otimes \Lambda \otimes \Lambda$ to the linearly independent family $(m_\mu(\mathbf{x}) m_\nu(\mathbf{y}) m_\lambda(\mathbf{z}))_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$. Consequently, this map is injective[582]. Therefore, the family $(q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z}))_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$ of elements of $\mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$ is also linearly independent (because it is the image of the basis $(q_\mu \otimes q_\nu \otimes q_\lambda)_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$ of $\Lambda \otimes \Lambda \otimes \Lambda$ under this injective map[583]). If the sums appearing in (2.5.5) were finite, then this observation would already yield Exercise 2.5.5 (c). However, these sums are infinite (and linear independence makes no claims about infinite sums being 0), so the solution of Exercise 2.5.5 (c) takes some more work:

Let $(a_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} \in \mathbf{k}^{\operatorname{Par}^3}$ and $(b_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} \in \mathbf{k}^{\operatorname{Par}^3}$ be two families satisfying (2.5.5) in $\mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$. We must prove that $(a_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} = (b_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$.

For each $(\mu,\nu,\lambda) \in \operatorname{Par}^3$,

$$\text{the power series } q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z}) \text{ is homogeneous of degree } |\mu| + |\nu| + |\lambda| \tag{13.54.14}$$

[584].

Fix $n \in \mathbb{N}$. Note that there are only finitely many $(\mu,\nu,\lambda) \in \operatorname{Par}^3$ satisfying $|\mu| + |\nu| + |\lambda| = n$ [585].

Consider the $\mathbf{k}$-linear map $\pi_n : \mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]] \to \mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$ that sends each power series $f \in \mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$ to its homogeneous component of degree n. Thus, π_n has the following properties:

- If $f \in \mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$ is a power series that is homogeneous of degree n, then

$$\pi_n(f) = f. \tag{13.54.15}$$

- If $f \in \mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$ is a power series that is homogeneous of degree $\neq n$, then

$$\pi_n(f) = 0. \tag{13.54.16}$$

- The map π_n is $\mathbf{k}$-linear and continuous (with respect to the topology on $\mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z}]]$).

Hence, each $(\mu,\nu,\lambda) \in \operatorname{Par}^3$ satisfying $|\mu| + |\nu| + |\lambda| = n$ satisfies

$$\pi_n(q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})) = q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z}) \tag{13.54.17}$$

[586]. Furthermore, each $(\mu,\nu,\lambda) \in \operatorname{Par}^3$ satisfying $|\mu| + |\nu| + |\lambda| \neq n$ satisfies

$$\pi_n(q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})) = 0 \tag{13.54.18}$$

[587].

so that

$$c_{\alpha,\beta,\gamma} = \left[\mathbf{x}^\alpha \mathbf{y}^\beta \mathbf{z}^\gamma\right] \left(\underbrace{\sum_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} c_{\mu,\nu,\lambda} m_\mu(\mathbf{x}) m_\nu(\mathbf{y}) m_\lambda(\mathbf{z})}_{=0} \right) = \left[\mathbf{x}^\alpha \mathbf{y}^\beta \mathbf{z}^\gamma\right] 0 = 0.$$

Now, forget that we fixed (α,β,γ). We thus have shown that $c_{\alpha,\beta,\gamma} = 0$ for each $(\alpha,\beta,\gamma) \in \operatorname{Par}^3$. In other words, $(c_{\alpha,\beta,\gamma})_{(\alpha,\beta,\gamma)\in \operatorname{Par}^3} = (0)_{(\alpha,\beta,\gamma)\in \operatorname{Par}^3}$. Renaming the index (α,β,γ) as (μ,ν,λ) in this equality, we obtain $(c_{\mu,\nu,\lambda})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} = (0)_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$. Qed.

[582] because any $\mathbf{k}$-linear map that maps a basis of its domain to a linearly independent family must be injective

[583] Here, we are using the fact that the image of a basis under an injective $\mathbf{k}$-linear map is always linearly independent.

[584] *Proof of (13.54.14):* Let $(\mu,\nu,\lambda) \in \operatorname{Par}^3$.

The power series $q_\lambda(\mathbf{x}) = q_\lambda$ is homogeneous of degree $|\lambda|$ (by (13.54.1)). Renaming the indeterminates $\mathbf{x}$ as $\mathbf{z}$ in this fact, we conclude that the power series $q_\lambda(\mathbf{z})$ is homogeneous of degree $|\lambda|$. Similarly, the power series $q_\mu(\mathbf{x})$ is homogeneous of degree $|\mu|$. Similarly, the power series $q_\nu(\mathbf{y})$ is homogeneous of degree $|\nu|$.

Now, we know that the three power series $q_\mu(\mathbf{x}), q_\nu(\mathbf{y}), q_\lambda(\mathbf{z})$ are homogeneous of degrees $|\mu|, |\nu|, |\lambda|$, respectively. Hence, their product $q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})$ is homogeneous of degree $|\mu| + |\nu| + |\lambda|$. This proves (13.54.14).

[585] *Proof.* If $(\mu,\nu,\lambda) \in \operatorname{Par}^3$ satisfies $|\mu| + |\nu| + |\lambda| = n$, then each of the three partitions μ,ν,λ has to have size $\leq n$ (because $|\mu| \leq |\mu| + |\nu| + |\lambda| = n$, and similarly $|\nu| \leq n$ and $|\lambda| \leq n$). This leaves only finitely many possibilities for each of these partitions μ,ν,λ. Thus, there are only finitely many $(\mu,\nu,\lambda) \in \operatorname{Par}^3$ satisfying $|\mu| + |\nu| + |\lambda| = n$.

[586] *Proof of (13.54.17):* Let $(\mu,\nu,\lambda) \in \operatorname{Par}^3$ be such that $|\mu| + |\nu| + |\lambda| = n$. From (13.54.14), we know that the power series $q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})$ is homogeneous of degree $|\mu| + |\nu| + |\lambda| = n$. Hence, (13.54.15) (applied to $f = q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})$) yields $\pi_n(q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})) = q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})$. This proves (13.54.17).

[587] *Proof of (13.54.18):* Let $(\mu,\nu,\lambda) \in \operatorname{Par}^3$ be such that $|\mu| + |\nu| + |\lambda| \neq n$. From (13.54.14), we know that the power series $q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})$ is homogeneous of degree $|\mu| + |\nu| + |\lambda| \neq n$. Hence, (13.54.16) (applied to $f = q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})$) yields $\pi_n(q_\mu(\mathbf{x}) q_\nu(\mathbf{y}) q_\lambda(\mathbf{z})) = 0$. This proves (13.54.18).

But the map π_n is $\mathbf{k}$-linear and continuous. Thus, it respects infinite sums. Hence,

$$\begin{aligned}
&\pi_n \left(\sum_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} a_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) \right) \\
&= \sum_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} a_{\lambda,\mu,\nu} \pi_n (q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z})) \\
&= \sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|=n}} a_{\lambda,\mu,\nu} \underbrace{\pi_n (q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}))}_{\substack{=q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) \\ \text{(by (13.54.17))}}} + \sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|\neq n}} a_{\lambda,\mu,\nu} \underbrace{\pi_n (q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}))}_{\substack{=0 \\ \text{(by (13.54.18))}}} \\
&= \sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|=n}} a_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) + \underbrace{\sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|\neq n}} a_{\lambda,\mu,\nu} 0}_{=0} \\
&= \sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|=n}} a_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) . \qquad (13.54.19)
\end{aligned}$$

The same argument (applied to the family $(b_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$ instead of $(a_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$) yields

$$\pi_n \left(\sum_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} b_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) \right) = \sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|=n}} b_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) . \qquad (13.54.20)$$

Now, applying the map π_n to both sides of the equality (2.5.5), we obtain

$$\begin{aligned}
&\pi_n \left(\sum_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} a_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) \right) \\
&= \pi_n \left(\sum_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} b_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) \right) = \sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|=n}} b_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) .
\end{aligned}$$

Comparing this with (13.54.19), we obtain

$$\sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|=n}} a_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) = \sum_{\substack{(\mu,\nu,\lambda)\in \operatorname{Par}^3; \\ |\mu|+|\nu|+|\lambda|=n}} b_{\lambda,\mu,\nu} q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}) . \qquad (13.54.21)$$

Notice that both sums appearing in this equality are finite (since there are only finitely many $(\mu, \nu, \lambda) \in \operatorname{Par}^3$ satisfying $|\mu| + |\nu| + |\lambda| = n$). Since the family $(q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}))_{(\mu,\nu,\lambda)\in \operatorname{Par}^3;\ |\mu|+|\nu|+|\lambda|=n}$ is $\mathbf{k}$-linearly independent[588], we can thus conclude from (13.54.21) that

$$a_{\lambda,\mu,\nu} = b_{\lambda,\mu,\nu} \qquad \text{for each } (\mu, \nu, \lambda) \in \operatorname{Par}^3 \text{ satisfying } |\mu| + |\nu| + |\lambda| = n. \qquad (13.54.22)$$

Now, forget that we fixed n. We thus have proven (13.54.22) for each $n \in \mathbb{N}$.

Now, let $(\mu, \nu, \lambda) \in \operatorname{Par}^3$ be arbitrary. Then, $|\mu| + |\nu| + |\lambda| \in \mathbb{N}$. Hence, (13.54.22) (applied to $n = |\mu| + |\nu| + |\lambda|$) yields $a_{\lambda,\mu,\nu} = b_{\lambda,\mu,\nu}$.

Now, forget that we fixed (μ, ν, λ). We thus have proven that $a_{\lambda,\mu,\nu} = b_{\lambda,\mu,\nu}$ for each $(\mu, \nu, \lambda) \in \operatorname{Par}^3$. In other words, $(a_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3} = (b_{\lambda,\mu,\nu})_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$. This solves Exercise 2.5.5 (c).

(b) The solution to Exercise 2.5.5 (b) is analogous to that of Exercise 2.5.5 (c) (the difference being that there are now just two families $\mathbf{x}$ and $\mathbf{y}$ of indeterminates, rather than three families $\mathbf{x}$, $\mathbf{y}$ and $\mathbf{z}$).

---

[588] *Proof.* We know that the family $(q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}))_{(\mu,\nu,\lambda)\in \operatorname{Par}^3}$ is $\mathbf{k}$-linearly independent. Hence, the family $(q_\mu (\mathbf{x}) q_\nu (\mathbf{y}) q_\lambda (\mathbf{z}))_{(\mu,\nu,\lambda)\in \operatorname{Par}^3;\ |\mu|+|\nu|+|\lambda|=n}$ (being a subfamily of it) must also be $\mathbf{k}$-linearly independent.

13.55. **Solution to Exercise 2.5.10.** *Solution to Exercise 2.5.10.* Recall that $(s_\kappa)_{\kappa \in \operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, $(s_\kappa \otimes s_\lambda)_{(\kappa,\lambda)\in \operatorname{Par}\times\operatorname{Par}}$ is a basis of the $\mathbf{k}$-module $\Lambda\otimes\Lambda$. We will refer to this basis as the "Schur basis" of $\Lambda\otimes\Lambda$.

Now, the first diagram in (1.3.4) commutes when A is set to Λ (since Λ is a bialgebra). In other words,

$$\Delta\circ m = (m\otimes m)\circ(\operatorname{id}\otimes T\otimes\operatorname{id})\circ(\Delta\otimes\Delta) : \Lambda\otimes\Lambda\to\Lambda\otimes\Lambda. \tag{13.55.1}$$

Fix four partitions φ, ψ, κ and λ. Applying both sides of the equality (13.55.1) to $s_\varphi\otimes s_\psi$, we obtain

$$(\Delta\circ m)(s_\varphi\otimes s_\psi) = ((m\otimes m)\circ(\operatorname{id}\otimes T\otimes\operatorname{id})\circ(\Delta\otimes\Delta))(s_\varphi\otimes s_\psi).$$

Comparing the coefficients before $s_\kappa\otimes s_\lambda$ in this equality, we obtain

$$\sum_{\rho\in\operatorname{Par}} c^\rho_{\kappa,\lambda} c^\rho_{\varphi,\psi} = \sum_{(\alpha,\beta,\gamma,\delta)\in\operatorname{Par}^4} c^\kappa_{\alpha,\gamma} c^\lambda_{\beta,\delta} c^\varphi_{\alpha,\beta} c^\psi_{\gamma,\delta}$$

(after a straightforward computation using (2.5.6), (2.5.7) and Corollary 2.5.7). This solves the exercise.

13.56. **Solution to Exercise 2.5.11.** *Solution to Exercise 2.5.11.* Before we step to the solution of this problem, let us make some general observations.

- Every two partitions λ and μ satisfy $s_{\lambda/\mu} = \sum_\nu c^\lambda_{\mu,\nu} s_\nu$, where the sum ranges over all partitions ν (according to Remark 2.5.9). In other words, every two partitions λ and μ satisfy

$$s_{\lambda/\mu} = \sum_{\nu\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\nu. \tag{13.56.1}$$

- On the other hand, (2.5.6) yields

$$s_\mu s_\nu = \sum_{\lambda\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\lambda \qquad \text{for any two partitions } \mu \text{ and } \nu. \tag{13.56.2}$$

(a) Let μ be a partition. We have

$$\sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x}) \underbrace{s_{\lambda/\mu}(\mathbf{y})}_{\substack{=\sum_{\nu\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\nu(\mathbf{y}) \\ \text{(by (13.56.1), evaluated} \\ \text{at the variable set } \mathbf{y})}} = \sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x}) \sum_{\nu\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\nu(\mathbf{y}). \tag{13.56.3}$$

On the other hand, (2.5.1) yields

$$\prod_{i,j=1}^\infty (1-x_iy_j)^{-1} = \sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x}) s_\lambda(\mathbf{y}) = \sum_{\nu\in\operatorname{Par}} s_\nu(\mathbf{x}) s_\nu(\mathbf{y})$$

(here, we renamed the summation index λ as ν). Multiplying this equality with $s_\mu(\mathbf{x})$, we obtain

$$\begin{aligned} s_\mu(\mathbf{x})\cdot\prod_{i,j=1}^\infty (1-x_iy_j)^{-1} &= s_\mu(\mathbf{x})\cdot\sum_{\nu\in\operatorname{Par}} s_\nu(\mathbf{x}) s_\nu(\mathbf{y}) = \sum_{\nu\in\operatorname{Par}} \underbrace{s_\mu(\mathbf{x}) s_\nu(\mathbf{x})}_{\substack{=\sum_{\lambda\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\lambda(\mathbf{x}) \\ \text{(by (13.56.2))}}} s_\nu(\mathbf{y}) \\ &= \sum_{\nu\in\operatorname{Par}} \left(\sum_{\lambda\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\lambda(\mathbf{x})\right) s_\nu(\mathbf{y}) = \sum_{\lambda\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\lambda(\mathbf{x}) \sum_{\nu\in\operatorname{Par}} s_\nu(\mathbf{y}) \\ &= \sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x}) \sum_{\nu\in\operatorname{Par}} c^\lambda_{\mu,\nu} s_\nu(\mathbf{y}). \end{aligned}$$

Compared with (13.56.3), this yields

$$\sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x}) s_{\lambda/\mu}(\mathbf{y}) = s_\mu(\mathbf{x})\cdot\prod_{i,j=1}^\infty (1-x_iy_j)^{-1}.$$

This solves Exercise 2.5.11(a).

(b) Let $\mathbf{k}[[\mathbf{x},\mathbf{y},\mathbf{z},\mathbf{w}]]$ denote the ring

$$\mathbf{k}[[x_1,x_2,x_3,...,y_1,y_2,y_3,...,z_1,z_2,z_3,...,w_1,w_2,w_3,...]].$$

This ring clearly contains $\mathbf{k}[[\mathbf{x},\mathbf{y}]]$ as a subring. We will use the obvious abbreviations for variable sets: $\mathbf{x}=(x_1,x_2,x_3,...)$, $(\mathbf{x},\mathbf{z})=(x_1,x_2,x_3,...,z_1,z_2,z_3,...)$, etc.

Every partition λ satisfies

$$\begin{aligned} s_\lambda(\mathbf{y},\mathbf{x}) &= s_\lambda(\mathbf{x},\mathbf{y}) = \sum_{\mu\subseteq\lambda} s_\mu(\mathbf{x})\,s_{\lambda/\mu}(\mathbf{y}) \qquad \text{(by (2.3.3))} \\ &= \sum_{\mu\in\mathrm{Par}} s_\mu(\mathbf{x})\,s_{\lambda/\mu}(\mathbf{y}) - \sum_{\substack{\mu\in\mathrm{Par};\\ \mu\not\subseteq\lambda}} s_\mu(\mathbf{x})\underbrace{s_{\lambda/\mu}(\mathbf{y})}_{\substack{=0\\ (\text{since } \mu\not\subseteq\lambda)}} = \sum_{\mu\in\mathrm{Par}} s_\mu(\mathbf{x})\,s_{\lambda/\mu}(\mathbf{y}) - \underbrace{\sum_{\substack{\mu\in\mathrm{Par};\\ \mu\not\subseteq\lambda}} s_\mu(\mathbf{x})\,0}_{=0} \\ &= \sum_{\mu\in\mathrm{Par}} s_\mu(\mathbf{x})\,s_{\lambda/\mu}(\mathbf{y}). \end{aligned}$$

Applying this equality to the variables $\mathbf{z}$ and $\mathbf{x}$ instead of $\mathbf{x}$ and $\mathbf{y}$, we obtain

$$s_\lambda(\mathbf{x},\mathbf{z}) = \sum_{\mu\in\mathrm{Par}} s_\mu(\mathbf{z})\,s_{\lambda/\mu}(\mathbf{x}). \tag{13.56.4}$$

Applying this equality to the variables $\mathbf{y}$ and $\mathbf{w}$ instead of $\mathbf{x}$ and $\mathbf{z}$, we obtain

$$s_\lambda(\mathbf{y},\mathbf{w}) = \sum_{\mu\in\mathrm{Par}} s_\mu(\mathbf{w})\,s_{\lambda/\mu}(\mathbf{y}) = \sum_{\nu\in\mathrm{Par}} s_\nu(\mathbf{w})\,s_{\lambda/\nu}(\mathbf{y}) \tag{13.56.5}$$

(here, we renamed the summation index μ as ν) for any partition λ.

Now,

$$\begin{aligned} &\prod_{i,j=1}^{\infty}(1-x_iy_j)^{-1}\prod_{i,j=1}^{\infty}(1-x_iw_j)^{-1}\prod_{i,j=1}^{\infty}(1-z_iy_j)^{-1}\prod_{i,j=1}^{\infty}(1-z_iw_j)^{-1} \\ &= \prod_{\substack{a\in(\mathbf{x},\mathbf{z});\\ b\in(\mathbf{y},\mathbf{w})}}(1-ab)^{-1} = \sum_{\lambda\in\mathrm{Par}} \underbrace{s_\lambda(\mathbf{x},\mathbf{z})}_{\substack{=\sum_{\mu\in\mathrm{Par}} s_\mu(\mathbf{z})s_{\lambda/\mu}(\mathbf{x})\\ (\text{by (13.56.4)})}} \underbrace{s_\lambda(\mathbf{y},\mathbf{w})}_{\substack{=\sum_{\nu\in\mathrm{Par}} s_\nu(\mathbf{w})s_{\lambda/\nu}(\mathbf{y})\\ (\text{by (13.56.5)})}} \\ &\qquad \text{(by (2.5.1), applied to the variable sets } (\mathbf{x},\mathbf{z}) \text{ and } (\mathbf{y},\mathbf{w}) \text{ instead of } \mathbf{x} \text{ and } \mathbf{y}) \\ &= \sum_{\lambda\in\mathrm{Par}}\left(\sum_{\mu\in\mathrm{Par}} s_\mu(\mathbf{z})\,s_{\lambda/\mu}(\mathbf{x})\right)\left(\sum_{\nu\in\mathrm{Par}} s_\nu(\mathbf{w})\,s_{\lambda/\nu}(\mathbf{y})\right) \\ &= \sum_{\mu\in\mathrm{Par}}\sum_{\nu\in\mathrm{Par}} s_\mu(\mathbf{z})\,s_\nu(\mathbf{w})\left(\sum_{\lambda\in\mathrm{Par}} s_{\lambda/\mu}(\mathbf{x})\,s_{\lambda/\nu}(\mathbf{y})\right). \qquad (13.56.6) \end{aligned}$$

On the other hand, every partition κ satisfies

$$\sum_{\lambda\in\mathrm{Par}} s_\lambda(\mathbf{x})\,s_{\lambda/\kappa}(\mathbf{y}) = s_\kappa(\mathbf{x})\cdot\prod_{i,j=1}^{\infty}(1-x_iy_j)^{-1} \tag{13.56.7}$$

(by Exercise 2.5.11(a), applied to κ instead of μ). Applying this to the variable sets $\mathbf{w}$ and $\mathbf{x}$ instead of $\mathbf{x}$ and $\mathbf{y}$, we obtain

$$\begin{aligned}
\sum_{\lambda\in\mathrm{Par}} s_{\lambda}(\mathbf{w})\, s_{\lambda/\kappa}(\mathbf{x}) &= s_{\kappa}(\mathbf{w}) \cdot \underbrace{\prod_{i,j=1}^{\infty} (1-w_i x_j)^{-1}}_{\substack{=\prod_{i,j=1}^{\infty}(1-x_j w_i)^{-1} \\ =\prod_{j,i=1}^{\infty}(1-x_i w_j)^{-1} \\ \text{(here, we renamed the index (i,j) as (j,i))}}} \\
&= s_{\kappa}(\mathbf{w}) \cdot \underbrace{\prod_{j,i=1}^{\infty}}_{=\prod_{i,j=1}^{\infty}} (1-x_i w_j)^{-1} = s_{\kappa}(\mathbf{w}) \cdot \prod_{i,j=1}^{\infty} (1-x_i w_j)^{-1} \qquad (13.56.8)
\end{aligned}$$

for every partition κ. But applying both sides of the identity (13.56.7) to the variable set $\mathbf{z}$ instead of $\mathbf{x}$, and renaming the summation index λ as μ on the left hand side of this equality, we obtain

$$\sum_{\mu\in\mathrm{Par}} s_{\mu}(\mathbf{z})\, s_{\mu/\kappa}(\mathbf{y}) = s_{\kappa}(\mathbf{z}) \cdot \prod_{i,j=1}^{\infty} (1-z_i y_j)^{-1}. \tag{13.56.9}$$

Now, applying (2.5.1) to the variable sets $\mathbf{z}$ and $\mathbf{w}$ instead of $\mathbf{x}$ and $\mathbf{y}$, we obtain

$$\prod_{i,j=1}^{\infty} (1-z_i w_j)^{-1} = \sum_{\lambda\in\mathrm{Par}} s_{\lambda}(\mathbf{z})\, s_{\lambda}(\mathbf{w}) = \sum_{\kappa\in\mathrm{Par}} s_{\kappa}(\mathbf{z})\, s_{\kappa}(\mathbf{w}).$$

Hence,

$$\begin{aligned}
&\prod_{i,j=1}^{\infty} (1-x_i y_j)^{-1} \prod_{i,j=1}^{\infty} (1-x_i w_j)^{-1} \prod_{i,j=1}^{\infty} (1-z_i y_j)^{-1} \underbrace{\prod_{i,j=1}^{\infty} (1-z_i w_j)^{-1}}_{=\sum_{\kappa\in\mathrm{Par}} s_{\kappa}(\mathbf{z}) s_{\kappa}(\mathbf{w})} \\
&= \prod_{i,j=1}^{\infty} (1-x_i y_j)^{-1} \prod_{i,j=1}^{\infty} (1-x_i w_j)^{-1} \prod_{i,j=1}^{\infty} (1-z_i y_j)^{-1} \cdot \sum_{\kappa\in\mathrm{Par}} s_{\kappa}(\mathbf{z})\, s_{\kappa}(\mathbf{w}) \\
&= \prod_{i,j=1}^{\infty} (1-x_i y_j)^{-1} \cdot \sum_{\kappa\in\mathrm{Par}} \underbrace{\left(s_{\kappa}(\mathbf{w}) \cdot \prod_{i,j=1}^{\infty} (1-x_i w_j)^{-1} \right)}_{\substack{=\sum_{\lambda\in\mathrm{Par}} s_{\lambda}(\mathbf{w}) s_{\lambda/\kappa}(\mathbf{x}) \\ \text{(by (13.56.8))}}} \underbrace{\left(s_{\kappa}(\mathbf{z}) \cdot \prod_{i,j=1}^{\infty} (1-z_i y_j)^{-1} \right)}_{\substack{=\sum_{\mu\in\mathrm{Par}} s_{\mu}(\mathbf{z}) s_{\mu/\kappa}(\mathbf{y}) \\ \text{(by (13.56.9))}}} \\
&= \prod_{i,j=1}^{\infty} (1-x_i y_j)^{-1} \cdot \sum_{\kappa\in\mathrm{Par}} \left(\sum_{\lambda\in\mathrm{Par}} s_{\lambda}(\mathbf{w})\, s_{\lambda/\kappa}(\mathbf{x}) \right) \left(\sum_{\mu\in\mathrm{Par}} s_{\mu}(\mathbf{z})\, s_{\mu/\kappa}(\mathbf{y}) \right) \\
&= \sum_{\mu\in\mathrm{Par}} \sum_{\lambda\in\mathrm{Par}} s_{\mu}(\mathbf{z})\, s_{\lambda}(\mathbf{w}) \left(\sum_{\kappa\in\mathrm{Par}} s_{\lambda/\kappa}(\mathbf{x})\, s_{\mu/\kappa}(\mathbf{y}) \right) \cdot \prod_{i,j=1}^{\infty} (1-x_i y_j)^{-1} \\
&= \sum_{\mu\in\mathrm{Par}} \sum_{\nu\in\mathrm{Par}} s_{\mu}(\mathbf{z})\, s_{\nu}(\mathbf{w}) \left(\sum_{\rho\in\mathrm{Par}} s_{\nu/\rho}(\mathbf{x})\, s_{\mu/\rho}(\mathbf{y}) \right) \cdot \prod_{i,j=1}^{\infty} (1-x_i y_j)^{-1}
\end{aligned}$$

(here, we renamed the summation indices λ and κ as ν and ρ, respectively). Comparing this with (13.56.6), we obtain

$$\sum_{\mu\in\operatorname{Par}}\sum_{\nu\in\operatorname{Par}} s_\mu(\mathbf{z})\, s_\nu(\mathbf{w}) \left(\sum_{\lambda\in\operatorname{Par}} s_{\lambda/\mu}(\mathbf{x})\, s_{\lambda/\nu}(\mathbf{y})\right)$$
$$= \sum_{\mu\in\operatorname{Par}}\sum_{\nu\in\operatorname{Par}} s_\mu(\mathbf{z})\, s_\nu(\mathbf{w}) \left(\sum_{\rho\in\operatorname{Par}} s_{\nu/\rho}(\mathbf{x})\, s_{\mu/\rho}(\mathbf{y})\right) \cdot \prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1}.$$

We can regard this as an identity in the ring $(\mathbf{k}[[\mathbf{x},\mathbf{y}]])[[\mathbf{z},\mathbf{w}]]$ of formal power series in the variables $(\mathbf{z},\mathbf{w}) = (z_1, z_2, z_3, ..., w_1, w_2, w_3, ...)$ over the ring $\mathbf{k}[[\mathbf{x},\mathbf{y}]]$. Extracting the coefficients in front of $s_\alpha(\mathbf{z})\, s_\beta(\mathbf{w})$ in this identity[589], we obtain

$$\sum_{\lambda\in\operatorname{Par}} s_{\lambda/\alpha}(\mathbf{x})\, s_{\lambda/\beta}(\mathbf{y}) = \left(\sum_{\rho\in\operatorname{Par}} s_{\beta/\rho}(\mathbf{x})\, s_{\alpha/\rho}(\mathbf{y})\right) \cdot \prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1}.$$

This solves Exercise 2.5.11(b).

13.57. **Solution to Exercise 2.5.13.** *Solution to Exercise 2.5.13.* We know that $(s_\lambda)_{\lambda\in\operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ, but we can also say something more specific: For every $n \in \mathbb{N}$, the family $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n [590].

The basis $(s_\lambda)_{\lambda\in\operatorname{Par}}$ of Λ is orthonormal with respect to the Hall inner product. In other words,

$$(s_\lambda, s_\mu) = \delta_{\lambda,\mu} \qquad \text{for any partitions } \lambda \text{ and } \mu. \tag{13.57.1}$$

(a) Let n and m be two distinct nonnegative integers. Let $f \in \Lambda_n$ and $g \in \Lambda_m$.

We need to prove that $(f, g) = 0$. Since this equality is $\mathbf{k}$-linear in f, we can WLOG assume that f is an element of the basis $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ of Λ_n. In other words, we can WLOG assume that $f = s_\lambda$ for some $\lambda \in \operatorname{Par}_n$. Assume this, and similarly assume that $g = s_\mu$ for some $\mu \in \operatorname{Par}_m$. These two partitions λ and μ must be

[589] This notion of "extracting the coefficients" relies on the fact that if two families $(a_{\mu,\nu})_{(\mu,\nu)\in\operatorname{Par}^2} \in \mathbf{k}[[\mathbf{x},\mathbf{y}]]^{\operatorname{Par}^2}$ and $(b_{\mu,\nu})_{(\mu,\nu)\in\operatorname{Par}^2} \in \mathbf{k}[[\mathbf{x},\mathbf{y}]]^{\operatorname{Par}^2}$ satisfy

$$\sum_{(\mu,\nu)\in\operatorname{Par}^2} a_{\mu,\nu} s_\mu(\mathbf{z}) s_\nu(\mathbf{w}) = \sum_{(\mu,\nu)\in\operatorname{Par}^2} b_{\mu,\nu} s_\mu(\mathbf{z}) s_\nu(\mathbf{w})$$

in $(\mathbf{k}[[\mathbf{x},\mathbf{y}]])[[\mathbf{z},\mathbf{w}]]$, then $(a_{\mu,\nu})_{(\mu,\nu)\in\operatorname{Par}^2} = (b_{\mu,\nu})_{(\mu,\nu)\in\operatorname{Par}^2}$. This fact is a consequence of Exercise 2.5.5(b), applied to $q_\lambda = s_\lambda$ (with the base ring $\mathbf{k}$ replaced by $\mathbf{k}[[\mathbf{x},\mathbf{y}]]$, and with the families $\mathbf{x}$ and $\mathbf{y}$ renamed as $\mathbf{z}$ and $\mathbf{w}$).

[590] *Proof.* We have $s_\lambda \in \Lambda_{|\lambda|} = \Lambda_n$ for every $\lambda \in \operatorname{Par}_n$. Thus, $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ is a family of elements of Λ_n. This family is $\mathbf{k}$-linearly independent (because it is part of the basis $(s_\lambda)_{\lambda\in\operatorname{Par}}$ of Λ). It remains to prove that this family spans the $\mathbf{k}$-module Λ_n.

Let $f \in \Lambda_n$. We can write f in the form $f = \sum_{\lambda\in\operatorname{Par}} a_\lambda s_\lambda$ for some family $(a_\lambda)_{\lambda\in\operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ of scalars. Consider this $(a_\lambda)_{\lambda\in\operatorname{Par}}$ and notice that

$$f = \sum_{\lambda\in\operatorname{Par}} a_\lambda s_\lambda = \sum_{\lambda\in\operatorname{Par}_n} a_\lambda s_\lambda + \sum_{\substack{\lambda\in\operatorname{Par};\\ \lambda\notin\operatorname{Par}_n}} a_\lambda s_\lambda,$$

so that $f - \sum_{\lambda\in\operatorname{Par}_n} a_\lambda s_\lambda = \sum_{\substack{\lambda\in\operatorname{Par};\\ \lambda\notin\operatorname{Par}_n}} a_\lambda s_\lambda$. The left hand side of this latter equality is homogeneous of degree n (since f and all the s_λ with $\lambda \in \operatorname{Par}_n$ are homogeneous of degree n), while the right hand side is a sum of homogeneous elements of degrees different from n. So the only way these two sides can be equal is if they both are 0. In particular, this shows that the left hand side is 0. In other words, $f - \sum_{\lambda\in\operatorname{Par}_n} a_\lambda s_\lambda = 0$, so that $f = \sum_{\lambda\in\operatorname{Par}_n} a_\lambda s_\lambda$. Hence, f is a $\mathbf{k}$-linear combination of the s_λ for $\lambda \in \operatorname{Par}_n$.

Since we have proven this for every $f \in \Lambda_n$, we thus conclude that the family $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ spans the $\mathbf{k}$-module Λ_n, qed.

distinct (because their sizes differ: $|\lambda| = n \neq m = |\mu|$), and so they satisfy $\delta_{\lambda,\mu} = 0$. Now,

$$\begin{aligned}\Bigg(\underbrace{f}_{=s_\lambda}, \underbrace{g}_{=s_\mu}\Bigg) &= (s_\lambda, s_\mu) = \delta_{\lambda,\mu} \qquad\qquad (\text{by } (13.57.1)) \\ &= 0.\end{aligned}$$

This solves Exercise 2.5.13(a).

(b) Let $n \in \mathbb{N}$ and $f \in \Lambda_n$.

We need to prove that $(h_n, f) = f(1)$. Since this equality is $\mathbf{k}$-linear in f, we can WLOG assume that f is an element of the basis $(s_\lambda)_{\lambda \in \operatorname{Par}_n}$ of Λ_n. In other words, we can WLOG assume that $f = s_\lambda$ for some $\lambda \in \operatorname{Par}_n$. Assume this.

We must be in one of the two cases:

Case 1: We have $\ell(\lambda) \leq 1$.

Case 2: We have $\ell(\lambda) > 1$.

Let us consider Case 1 first. In this case, $\ell(\lambda) \leq 1$. Hence, $\lambda = (n)$ (since $\lambda \in \operatorname{Par}_n$), so that $s_\lambda = s_{(n)}$. Hence, $f = s_\lambda = s_{(n)} = h_n$ and thus $f(1) = h_n(1) = 1$. Compared with

$$\begin{aligned}\Bigg(\underbrace{h_n}_{=s_{(n)}}, \underbrace{f}_{=s_{(n)}}\Bigg) &= \left(s_{(n)}, s_{(n)}\right) = \delta_{(n),(n)} \qquad\qquad (\text{by } (13.57.1)) \\ &= 1,\end{aligned}$$

this yields $(h_n, f) = f(1)$. Hence, $(h_n, f) = f(1)$ is proven in Case 1.

Let us now consider Case 2. In this case, $\ell(\lambda) > 1$, so the partition λ has more than 1 part. Exercise 2.3.8(b) (applied to 1 instead of n) thus yields $s_\lambda(x_1) = 0$. But $s_\lambda(1)$ can be seen as the result of substituting 1 for x_1 in $s_\lambda(x_1)$, and therefore must be 0 as well (since $s_\lambda(x_1) = 0$). Thus, we have $s_\lambda(1) = 0$. Since $f = s_\lambda$, we now have $f(1) = s_\lambda(1) = 0$. Compared with

$$\begin{aligned}\Bigg(\underbrace{h_n}_{=s_{(n)}}, \underbrace{f}_{=s_\lambda}\Bigg) &= \left(s_{(n)}, s_\lambda\right) = \delta_{(n),\lambda} \qquad\qquad (\text{by } (13.57.1)) \\ &= 0 \qquad\qquad (\text{since } (n) \neq \lambda \text{ (because } \ell((n)) = 1 < \ell(\lambda))),\end{aligned}$$

this yields $(h_n, f) = f(1)$. Hence, $(h_n, f) = f(1)$ is proven in Case 2.

Now, $(h_n, f) = f(1)$ is proven in both Cases, which solves Exercise 2.5.13(b).

(c) We know that the Hall inner product has an orthonormal basis (namely, $(s_\lambda)_{\lambda \in \operatorname{Par}}$). Thus, the Hall inner product is symmetric (since any bilinear form that has an orthonormal basis must be symmetric). In other words, $(f, g) = (g, f)$ for all $f \in \Lambda$ and $g \in \Lambda$. This solves Exercise 2.5.13(c).

13.58. **Solution to Exercise 2.5.18.** *Solution to Exercise 2.5.18.* (a) This is a well-known fact; for a proof, see Theorem 5.3 in Keith Conrad, *Universal Identities I*, http://www.math.uconn.edu/~kconrad/blurbs/. Another proof (more complicated, but with the advantage of proving a more general result) can be found in [86, proof of Corollary 0.2].

(b) Consider the endomorphism of the $\mathbf{k}$-module A defined by sending γ_i to β_i for every $i \in I$. This endomorphism is well-defined (since $(\gamma_i)_{i\in I}$ is a basis of A) and surjective (since the family $(\beta_i)_{i\in I}$ spans A), therefore is a $\mathbf{k}$-module isomorphism (according to Exercise 2.5.18(a)). As a consequence, it must send the basis $(\gamma_i)_{i\in I}$ of A to a basis of A (because a $\mathbf{k}$-module isomorphism sends any basis to a basis). Since it sends the basis $(\gamma_i)_{i\in I}$ to $(\beta_i)_{i\in I}$, this yields that $(\beta_i)_{i\in I}$ must be a basis of A. This solves Exercise 2.5.18(b).

13.59. Solution to Exercise 2.5.19.

Solution to Exercise 2.5.19. Fix $n \in \mathbb{N}$. Recall that $v_\lambda \in \Lambda_{|\lambda|}$ for each partition λ. Hence, for each $\lambda \in \operatorname{Par}_n$, we have $v_\lambda \in \Lambda_{|\lambda|} = \Lambda_n$ (since $|\lambda| = n$ (because $\lambda \in \operatorname{Par}_n$)). Thus, $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a family of elements of Λ_n.

But we have assumed that the family $(v_\lambda)_{\lambda \in \operatorname{Par}}$ spans the $\mathbf{k}$-module Λ. Since everything is graded, this yields that the family $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$ spans the $\mathbf{k}$-module Λ_n [591].

Recall that $v_\lambda \in \Lambda_n$ for each $\lambda \in \operatorname{Par}_n$. Hence, we can define the $\mathbf{k}$-linear map

$$\beta : \Lambda_n \to \Lambda_n, \qquad m_\lambda \mapsto v_\lambda \qquad \text{for every } \lambda \in \operatorname{Par}_n$$

(since $(m_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n). Consider this map β. This map β is surjective (since the family $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$ spans the $\mathbf{k}$-module Λ_n) [592].

But Λ_n is a finitely generated $\mathbf{k}$-module (since it has a finite basis $(m_\lambda)_{\lambda \in \operatorname{Par}_n}$). The map β is an endomorphism of this $\mathbf{k}$-module (since $\beta : \Lambda_n \to \Lambda_n$ is $\mathbf{k}$-linear), and is surjective. Thus, Exercise 2.5.18(a) (applied to this endomorphism) yields that β is a $\mathbf{k}$-module isomorphism.

Now, the map β satisfies $\beta(m_\lambda) = v_\lambda$ for each $\lambda \in \operatorname{Par}_n$ (by the definition of β). In other words, $(\beta(m_\lambda))_{\lambda \in \operatorname{Par}_n} = (v_\lambda)_{\lambda \in \operatorname{Par}_n}$.

But the family $(m_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n. Hence, the image of this family $(m_\lambda)_{\lambda \in \operatorname{Par}_n}$ under β is also a basis of the $\mathbf{k}$-module Λ_n (since β is a $\mathbf{k}$-module isomorphism). In other words, the

[591] *Proof.* Here is this argument in more detail:

Let $f \in \Lambda_n$. We shall prove that f is a $\mathbf{k}$-linear combination of the family $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$.

We have $f \in \Lambda_n \subset \Lambda$. Thus, f is a $\mathbf{k}$-linear combination of the family $(v_\lambda)_{\lambda \in \operatorname{Par}}$ (since the family $(v_\lambda)_{\lambda \in \operatorname{Par}}$ spans the $\mathbf{k}$-module Λ). In other words, there exists a family $(c_\lambda)_{\lambda \in \operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ such that (all but finitely many $\lambda \in \operatorname{Par}$ satisfy $c_\lambda = 0$) and $f = \sum_{\lambda \in \operatorname{Par}} c_\lambda v_\lambda$. Consider this $(c_\lambda)_{\lambda \in \operatorname{Par}}$.

Let $\pi_n : \Lambda \to \Lambda_n$ be the projection from the graded $\mathbf{k}$-module Λ onto its n-th graded component. Then, π_n is a $\mathbf{k}$-linear map with the properties that

$$\pi_n(g) = g \qquad \text{for each } g \in \Lambda_n, \tag{13.59.1}$$

and

$$\pi_n(g) = 0 \qquad \text{for each } g \in \Lambda_m \text{ for each } m \in \mathbb{N} \text{ satisfying } m \neq n. \tag{13.59.2}$$

If $\lambda \in \operatorname{Par}$ satisfies $|\lambda| = n$, then $v_\lambda \in \Lambda_{|\lambda|} = \Lambda_n$ (since $|\lambda| = n$) and thus

$$\pi_n(v_\lambda) = v_\lambda \tag{13.59.3}$$

(by (13.59.1), applied to $g = v_\lambda$).

If $\lambda \in \operatorname{Par}$ satisfies $|\lambda| \neq n$, then $v_\lambda \in \Lambda_{|\lambda|}$ and thus

$$\pi_n(v_\lambda) = 0 \tag{13.59.4}$$

(by (13.59.2), applied to $g = v_\lambda$ and $m = |\lambda|$).

Applying (13.59.1) to $g = f$, we obtain $\pi_n(f) = f$, so that

$$\begin{aligned} f &= \pi_n\left(\underbrace{f}_{=\sum_{\lambda \in \operatorname{Par}} c_\lambda v_\lambda}\right) = \pi_n\left(\sum_{\lambda \in \operatorname{Par}} c_\lambda v_\lambda\right) = \sum_{\lambda \in \operatorname{Par}} c_\lambda \pi_n(v_\lambda) \qquad (\text{since } \pi_n \text{ is a } \mathbf{k}\text{-linear map}) \\ &= \sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| = n}} c_\lambda \underbrace{\pi_n(v_\lambda)}_{\substack{= v_\lambda \\ (\text{by } (13.59.3))}} + \sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| \neq n}} c_\lambda \underbrace{\pi_n(v_\lambda)}_{\substack{= 0 \\ (\text{by } (13.59.4))}} \\ &\qquad (\text{since each } \lambda \in \operatorname{Par} \text{ satisfies either } |\lambda| = n \text{ or } |\lambda| \neq n \text{ (but not both)}) \\ &= \sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| = n}} c_\lambda v_\lambda + \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| \neq n}} c_\lambda 0}_{=0} = \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| = n}}}_{=\sum_{\lambda \in \operatorname{Par}_n}} c_\lambda v_\lambda = \sum_{\lambda \in \operatorname{Par}_n} c_\lambda v_\lambda. \end{aligned}$$

This shows that f is a $\mathbf{k}$-linear combination of the family $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$.

Now, forget that we fixed f. We thus have proven that every $f \in \Lambda_n$ is a $\mathbf{k}$-linear combination of the family $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$. Therefore, the family $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$ spans the $\mathbf{k}$-module Λ_n.

[592] *Proof.* In slightly more detail: The map β is $\mathbf{k}$-linear; thus, its image $\beta(\Lambda_n)$ is a $\mathbf{k}$-submodule of Λ_n. This $\mathbf{k}$-submodule $\beta(\Lambda_n)$ clearly contains v_λ for each $\lambda \in \operatorname{Par}_n$ (since the definition of β yields $v_\lambda = \beta(m_\lambda)$). Hence, $\beta(\Lambda_n)$ is a $\mathbf{k}$-submodule of Λ_n that contains v_λ for each $\lambda \in \operatorname{Par}_n$. But the only such $\mathbf{k}$-submodule is the whole module Λ_n (since the family $(v_\lambda)_{\lambda \in \operatorname{Par}_n}$ spans the $\mathbf{k}$-module Λ_n). Thus, we conclude that $\beta(\Lambda_n)$ must be the whole module Λ_n. In other words, β is surjective.

family $(v_\lambda)_{\lambda \in \mathrm{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n (since the image of the family $(m_\lambda)_{\lambda \in \mathrm{Par}_n}$ under β is $(\beta(m_\lambda))_{\lambda \in \mathrm{Par}_n} = (v_\lambda)_{\lambda \in \mathrm{Par}_n}$).

Forget that we fixed n. We thus have proved that $(v_\lambda)_{\lambda \in \mathrm{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n for each $n \in \mathbb{N}$. Hence, the family $(v_\lambda)_{\lambda \in \mathrm{Par}}$ is a graded basis of the $\mathbf{k}$-module $\bigoplus_{n \in \mathbb{N}} \Lambda_n$ (since $\mathrm{Par}_0, \mathrm{Par}_1, \mathrm{Par}_2, \ldots$ is a partition of the set Par). In other words, the family $(v_\lambda)_{\lambda \in \mathrm{Par}}$ is a graded basis of the $\mathbf{k}$-module Λ (since $\Lambda = \bigoplus_{n \in \mathbb{N}} \Lambda_n$). This solves Exercise 2.5.19.

13.60. **Solution to Exercise 2.5.20.** *Solution to Exercise 2.5.20.* (a) This can be solved by following the proof of Corollary 2.5.17, but in doing so one has to be careful about how one obtains the invertibility of A: it is no longer a consequence of A being a transition matrix between two bases (because we do not know in advance that $(u_\lambda)_{\lambda \in \mathrm{Par}}$ is a basis). Instead, one has to argue as in the footnote: The matrices A and B^t are block-diagonal, with each diagonal block corresponding to the partitions of size n for a given $n \in \mathbb{N}$ [593]. In particular, they are block-diagonal matrices with each block being a square matrix of finite size. It is known that if such a matrix is right-invertible, then it is left-invertible[594]; therefore, since A is right-invertible (because $AB^t = I$), we conclude that A is invertible.

(b) We know that for every partition λ, the symmetric functions h_λ and m_λ are two homogeneous elements of Λ, both of degree $|\lambda|$. We also know (from Proposition 2.5.15) that

$$\prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1} = \sum_{\lambda \in \mathrm{Par}} h_\lambda(\mathbf{x}) m_\lambda(\mathbf{y}).$$

Compared with (2.5.1), this yields $\sum_{\lambda \in \mathrm{Par}} s_\lambda(\mathbf{x}) s_\lambda(\mathbf{y}) = \sum_{\lambda \in \mathrm{Par}} h_\lambda(\mathbf{x}) m_\lambda(\mathbf{y})$. Thus, Exercise 2.5.20(a) (applied to $u_\lambda = h_\lambda$ and $v_\lambda = m_\lambda$) yields that $(h_\lambda)_{\lambda \in \mathrm{Par}}$ and $(m_\lambda)_{\lambda \in \mathrm{Par}}$ are $\mathbf{k}$-bases of Λ, and actually are dual bases with respect to the Hall inner product on Λ. In particular, $(h_\lambda)_{\lambda \in \mathrm{Par}}$ is a $\mathbf{k}$-basis of Λ. This solves Exercise 2.5.20(b).

Remark. We can use Exercise 2.5.20(b) to prove that $(e_\lambda)_{\lambda \in \mathrm{Par}}$ is a $\mathbf{k}$-basis of Λ as well (in a different way than we have done in the proof of Proposition 2.2.10). In fact, let us sketch this proof. We are going to proceed similarly to the above proof of Proposition 2.4.1, but with the roles of the families $(e_n)_{n \geq 1}$ and $(h_n)_{n \geq 1}$ switched.

We know (from Exercise 2.5.20(b)) that $(h_\lambda)_{\lambda \in \mathrm{Par}}$ is a $\mathbf{k}$-basis of Λ. In other words, the family $(h_n)_{n \geq 1}$ is algebraically independent and generates the $\mathbf{k}$-algebra Λ (by parts (b) and (c) of Exercise 2.2.14, applied to $v_n = h_n$ and $v_\lambda = h_\lambda$). Thus, we can define a $\mathbf{k}$-algebra homomorphism $\omega' : \Lambda \to \Lambda$ by setting

$$\omega'(h_n) = e_n \qquad \text{for every } n \geq 1. \tag{13.60.1}$$

[595] The identical form of the two recursions (2.4.6) and (2.4.7) shows that this ω' also satisfies

$$\omega'(e_n) = h_n \qquad \text{for each } n \geq 0. \tag{13.60.2}$$

[596] Combining this with (13.60.1), we conclude that $(\omega' \circ \omega')(h_n) = h_n$ for each $n \geq 1$. Therefore, the two $\mathbf{k}$-algebra homomorphisms $\omega' \circ \omega' : \Lambda \to \Lambda$ and $\mathrm{id} : \Lambda \to \Lambda$ agree on each element of the generating set $\{h_n\}$ of Λ. Hence, they are equal, i.e., we have $\omega' \circ \omega' = \mathrm{id}$. Hence, ω' is an involution, and therefore an automorphism of the $\mathbf{k}$-algebra Λ. In particular, ω' is a $\mathbf{k}$-module isomorphism $\Lambda \to \Lambda$. By multiplicativity and (13.60.1), we obtain

$$\omega'(h_\lambda) = e_\lambda \qquad \text{for every partition } \lambda. \tag{13.60.3}$$

[593] It is here that we are using the assumption that u_λ and v_λ are homogeneous of degree $|\lambda|$.

[594] In fact, it is clearly enough to prove this statement for square matrices of finite size (because block-diagonal matrices can be inverted block-by-block). However, for square matrices, this follows from the fact that a surjective endomorphism of a finitely-generated $\mathbf{k}$-module is an isomorphism (Exercise 2.5.18(a)).

[595] This ω' is, of course, precisely the ω constructed in the proof of Proposition 2.4.1. But we cannot use the ω constructed in the proof of Proposition 2.4.1 at this point, because its construction made use of the fact that $(e_\lambda)_{\lambda \in \mathrm{Par}}$ is a $\mathbf{k}$-basis of Λ (and we want to prove this fact).

[596] The details of this proof proceed just like the proof of (2.4.9), except for the fact that the e_n have traded places with the h_n.

Thus, the image of the basis $(h_\lambda)_{\lambda\in\mathrm{Par}}$ of Λ under the $\mathbf{k}$-module isomorphism ω' is the family $(e_\lambda)_{\lambda\in\mathrm{Par}}$. Therefore, this latter family $(e_\lambda)_{\lambda\in\mathrm{Par}}$ must be a basis of Λ (being the image of a basis under a $\mathbf{k}$-module isomorphism).

13.61. Solution to Exercise 2.5.21.

Solution to Exercise 2.5.21. When $\mathbb{Q}$ is a subring of $\mathbf{k}$, the statement of Exercise 2.5.21 has been proven in (2.5.13). However, there is no immediate way to reuse the proof of (2.5.13) in the general case (because this proof made use of logarithms, and these are only defined when $\mathbb{Q}$ is a subring of $\mathbf{k}$). Nevertheless, it is possible to imitate that proof by defining a notion of "logarithmic derivative" even in the absence of a logarithm. Let us elaborate on this.

Let A be any commutative ring. Whenever $Q \in A[[t]]$ is a formal power series with constant term 1, we define the *logarithmic derivative* of Q to be the power series $\dfrac{Q'}{Q} \in A[[t]]$ (where Q' denotes the derivative of Q, as usual). We denote this logarithmic derivative by $\operatorname{lder} Q$. When $\mathbb{Q}$ is a subring of A, we have $\operatorname{lder} Q = \dfrac{d}{dt}(\log Q)$, but the concept of $\operatorname{lder} Q$ is defined even when log is not. Some authors find it instructive to write $\dfrac{d}{dt}(\log Q)$ for $\operatorname{lder} Q$, but we prefer not to do so, since this might tempt us to write things which make no sense.

It is easy to see that the map

$$\begin{aligned}\{Q \in A[[t]] \ \mid\ Q \text{ has constant term } 1\} &\to A[[t]],\\ Q &\mapsto \operatorname{lder} Q\end{aligned}$$

is continuous (where we equip $A[[t]]$ with the usual topology – i.e., the product topology obtained by regarding the set $A[[t]]$ as a direct product of infinitely many copies of A). Moreover, whenever I is a set and $(Q_i)_{i\in I} \in (A[[t]])^I$ is a family of formal power series with constant term 1 such that the product $\prod_{i\in I} Q_i$ converges (with respect to our topology on $A[[t]]$), then

$$\operatorname{lder}\left(\prod_{i\in I} Q_i\right) = \sum_{i\in I} \operatorname{lder}(Q_i). \tag{13.61.1}$$

[597] This equality can be used as a substitute for the famous property of the logarithm to take products into sums in situations where the logarithm is not defined. Furthermore, we have

$$\operatorname{lder}\left(Q^{-1}\right) = -\operatorname{lder} Q \tag{13.61.2}$$

[597] *Proof of* (13.61.1)*:* Let I be a set, and let $(Q_i)_{i\in I} \in (A[[t]])^I$ be a family of formal power series with constant term 1 such that the product $\prod_{i\in I} Q_i$ converges (with respect to our topology on $A[[t]]$). We need to prove (13.61.1). Since the map

$$\begin{aligned}\{Q \in A[[t]] \ \mid\ Q \text{ has constant term } 1\} &\to A[[t]],\\ Q &\mapsto \operatorname{lder} Q\end{aligned}$$

is continuous (and since infinite products are limits of finite products, and infinite sums are limits of finite sums), we can WLOG assume that the set I is finite. Assuming this, we recall that the product rule for differentiating a product of several power series yields

$$\left(\prod_{i\in I} Q_i\right)' = \sum_{j\in I} Q_j' \left(\prod_{i\in I\setminus\{j\}} Q_i\right).$$

whenever $Q \in A[[t]]$ is a formal power series with constant term 1 (where Q^{-1} means the multiplicative inverse of Q) [598].

Now, set $A = \Lambda$. We have

$$H(t) = \prod_{i=1}^{\infty} (1 - x_i t)^{-1} = \prod_{i \in \{1,2,3,\ldots\}} (1 - x_i t)^{-1},$$

Now, by the definition of $\operatorname{lder}\left(\prod_{i\in I} Q_i\right)$, we have

$$\begin{aligned}
\operatorname{lder}\left(\prod_{i\in I} Q_i\right) &= \frac{\left(\prod_{i\in I} Q_i\right)'}{\prod_{i\in I} Q_i} = \frac{1}{\prod_{i\in I} Q_i} \underbrace{\left(\prod_{i\in I} Q_i\right)'}_{=\sum_{j\in I} Q_j'\left(\prod_{i\in I\setminus\{j\}} Q_i\right)} = \frac{1}{\prod_{i\in I} Q_i} \sum_{j\in I} Q_j' \left(\prod_{i\in I\setminus\{j\}} Q_i\right) \\
&= \sum_{j\in I} Q_j' \cdot \frac{\prod_{i\in I\setminus\{j\}} Q_i}{\prod_{i\in I} Q_i} = \sum_{j\in I} Q_j' \cdot \underbrace{\frac{\prod_{i\in I\setminus\{j\}} Q_i}{Q_j \prod_{i\in I\setminus\{j\}} Q_i}}_{=\frac{1}{Q_j}} \qquad \left(\text{since } \prod_{i\in I} Q_i = Q_j \prod_{i\in I\setminus\{j\}} Q_i \text{ for every } j \in I\right) \\
&= \sum_{j\in I} Q_j' \cdot \frac{1}{Q_j} = \sum_{j\in I} \underbrace{\frac{Q_j'}{Q_j}}_{\substack{=\operatorname{lder}(Q_j) \\ (\text{since } \operatorname{lder}(Q_j) \text{ is} \\ \text{defined as } \frac{Q_j'}{Q_j})}} = \sum_{j\in I} \operatorname{lder}(Q_j) = \sum_{i\in I} \operatorname{lder}(Q_i).
\end{aligned}$$

This proves (13.61.1).

[598] *Proof of* (13.61.2)*:* Let $Q \in A[[t]]$ be a formal power series with constant term 1. Then, the product rule for the derivative of a product of two power series yields $\left(QQ^{-1}\right)' = Q'Q^{-1} + Q\left(Q^{-1}\right)'$, so that $Q'Q^{-1} + Q\left(Q^{-1}\right)' = \Big(\underbrace{QQ^{-1}}_{=1}\Big)' = 1' = 0$ and thus $Q\left(Q^{-1}\right)' = -Q'Q^{-1}$, so that $\frac{\left(Q^{-1}\right)'}{Q^{-1}} = -\frac{Q'}{Q}$. But the definition of $\operatorname{lder}\left(Q^{-1}\right)$ yields $\operatorname{lder}\left(Q^{-1}\right) = \frac{\left(Q^{-1}\right)'}{Q^{-1}} = -\underbrace{\frac{Q'}{Q}}_{=\operatorname{lder} Q} = -\operatorname{lder} Q$. This proves (13.61.2).

so that

$$\begin{aligned}
\operatorname{lder}\left(H\left(t\right)\right) &= \operatorname{lder}\left(\prod_{i\in\{1,2,3,\ldots\}}\left(1-x_it\right)^{-1}\right) = \sum_{i\in\{1,2,3,\ldots\}} \underbrace{\operatorname{lder}\left(\left(1-x_it\right)^{-1}\right)}_{\substack{=-\operatorname{lder}(1-x_it) \\ \text{(by (13.61.2), applied to } Q=1-x_it)}} \\
&\qquad \left(\text{by (13.61.1), applied to } I=\{1,2,3,\ldots\} \text{ and } Q_i=\left(1-x_it\right)^{-1}\right) \\
&= \sum_{i\in\{1,2,3,\ldots\}}\left(-\underbrace{\operatorname{lder}\left(1-x_it\right)}_{\substack{=\dfrac{\left(1-x_it\right)'}{1-x_it} \\ \text{(by the definition of } \operatorname{lder}(1-x_it))}}\right) = \sum_{i\in\{1,2,3,\ldots\}} \underbrace{\left(-\frac{\left(1-x_it\right)'}{1-x_it}\right)}_{\substack{=-\dfrac{-x_i}{1-x_i}t \\ \text{(since } (1-x_it)'=-x_i)}} \\
&= \sum_{i\in\{1,2,3,\ldots\}} \underbrace{\left(-\frac{-x_i}{1-x_it}\right)}_{=x_i\cdot\dfrac{1}{1-x_it}} = \sum_{i\in\{1,2,3,\ldots\}} x_i \cdot \underbrace{\frac{1}{1-x_it}}_{=\sum_{m\geq 0}(x_it)^m=\sum_{m\geq 0}x_i^mt^m} \\
&= \sum_{i\in\{1,2,3,\ldots\}} x_i \cdot \sum_{m\geq 0} x_i^m t^m = \sum_{m\geq 0}\left(\sum_{i\in\{1,2,3,\ldots\}} \underbrace{x_i\cdot x_i^m}_{=x_i^{m+1}}\right)t^m \\
&= \sum_{m\geq 0}\underbrace{\left(\sum_{i\in\{1,2,3,\ldots\}} x_i^{m+1}\right)}_{=p_{m+1}} t^m = \sum_{m\geq 0} p_{m+1}t^m.
\end{aligned}$$

Thus,

$$\begin{aligned}
\sum_{m\geq 0} p_{m+1}t^m = \operatorname{lder}\left(H\left(t\right)\right) &= \frac{\left(H\left(t\right)\right)'}{H\left(t\right)} \qquad \left(\text{by the definition of } \operatorname{lder}\left(H\left(t\right)\right)\right) \\
&= \frac{H'\left(t\right)}{H\left(t\right)}.
\end{aligned}$$

This solves the exercise.

Remark: Another solution of Exercise 2.5.21 proceeds by noticing that the statement of this exercise can be rewritten in the form $\left(\sum_{m\geq 0} p_{m+1}t^m\right)\cdot H\left(t\right) = H'\left(t\right)$, which (by comparison of coefficients) is equivalent to saying that

$$\text{every } m\in\mathbb{N} \text{ satisfies } \sum_{i=0}^{m} p_{i+1}h_{m-i} = \left(m+1\right)h_{m+1}. \tag{13.61.3}$$

But it is clear that once (13.61.3) is proven for $\mathbf{k}=\mathbb{Z}$, it immediately follows that (13.61.3) also holds for all $\mathbf{k}$ (since $\Lambda_{\mathbf{k}} = \mathbf{k}\otimes_{\mathbb{Z}}\Lambda_{\mathbb{Z}}$). Proving (13.61.3) for $\mathbf{k}=\mathbb{Z}$, in turn, boils down to proving (13.61.3) for $\mathbf{k}=\mathbb{Q}$, which we already know how to do (from the proof of (2.5.13)).

13.62. **Solution to Exercise 2.5.22.** *Solution to Exercise 2.5.22.* For every partition λ, define an element $v_\lambda \in \Lambda$ by $v_\lambda = v_{\lambda_1}v_{\lambda_2}\cdots v_{\lambda_{\ell(\lambda)}}$. (This is well-defined, since $\lambda_1,\lambda_2,\ldots,\lambda_{\ell(\lambda)}$ are positive integers whenever λ is a partition.) Thus, Exercise 2.2.14(b) (applied to $A=\Lambda$) shows that the elements $v_1,v_2,v_3,\ldots$ generate the $\mathbf{k}$-algebra Λ if and only if the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ spans the $\mathbf{k}$-module Λ. Hence, the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ spans the $\mathbf{k}$-module Λ (since the elements $v_1, v_2, v_3, \ldots$ generate the $\mathbf{k}$-algebra Λ).

Furthermore, v_λ is an element of $\Lambda_{|\lambda|}$ for each partition λ [599]. Hence, Exercise 2.5.19 yields that the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is a graded basis of the graded $\mathbf{k}$-module Λ (where the indexing set Par is partitioned into $\operatorname{Par}_0, \operatorname{Par}_1, \operatorname{Par}_2, \ldots$). This solves Exercise 2.5.22(b).

(a) The family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ (since it is a graded basis of the graded $\mathbf{k}$-module Λ). Hence, in particular, this family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is $\mathbf{k}$-linearly independent.

But Exercise 2.2.14(c) (applied to $A = \Lambda$) yields that the elements $v_1, v_2, v_3, \ldots$ are algebraically independent over $\mathbf{k}$ if and only if the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is $\mathbf{k}$-linearly independent. Hence, the elements $v_1, v_2, v_3, \ldots$ are algebraically independent over $\mathbf{k}$ (since the family $(v_\lambda)_{\lambda\in\operatorname{Par}}$ is $\mathbf{k}$-linearly independent). This solves Exercise 2.5.22(a).

13.63. **Solution to Exercise 2.5.23.** *Solution to Exercise 2.5.23.* Let V denote the $\mathbf{k}$-subalgebra of Λ generated by $v_1, v_2, v_3, \ldots$. Thus, V is a $\mathbf{k}$-submodule of Λ.

We shall now show that

$$h_n \in V \qquad \text{for each positive integer } n. \tag{13.63.1}$$

[*Proof of (13.63.1):* We shall prove (13.63.1) by strong induction on n:

Induction step: Let m be a positive integer. Assume that (13.63.1) holds for all $n < m$. We must prove that (13.63.1) holds for $n = m$. In other words, we must prove that $h_m \in V$.

We have assumed that (13.63.1) holds for all $n < m$. In other words, we have

$$h_n \in V \qquad \text{for each positive integer } n < m. \tag{13.63.2}$$

We have assumed that the element $a_{(n)} \in \mathbf{k}$ is invertible for each positive integer n. Applying this to $n = m$, we conclude that the element $a_{(m)} \in \mathbf{k}$ is invertible. Hence, its inverse $a_{(m)}^{-1} \in \mathbf{k}$ is well-defined.

But we have also assumed that each positive integer n satisfies $v_n = \sum_{\lambda\in\operatorname{Par}_n} a_\lambda h_\lambda$. Applying this to $n = m$, we find

$$v_m = \sum_{\lambda\in\operatorname{Par}_m} a_\lambda h_\lambda = a_{(m)} h_{(m)} + \sum_{\substack{\lambda\in\operatorname{Par}_m;\\ \lambda\neq(m)}} a_\lambda h_\lambda$$

(here, we have split off the addend for $\lambda = (m)$ from the sum, since $(m) \in \operatorname{Par}_m$). Hence,

$$a_{(m)} h_{(m)} = v_m - \sum_{\substack{\lambda\in\operatorname{Par}_m;\\ \lambda\neq(m)}} a_\lambda h_\lambda. \tag{13.63.3}$$

[599] *Proof.* Let λ be a partition. Thus, $\lambda = \left(\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}\right)$, so that $|\lambda| = \lambda_1 + \lambda_2 + \cdots + \lambda_{\ell(\lambda)}$.

Let $i \in \{1, 2, \ldots, \ell(\lambda)\}$. Then, the number λ_i is a positive integer (by the definition of $\ell(\lambda)$). But recall that $v_n \in \Lambda_n$ for each positive integer n. Applying this to $n = \lambda_i$, we obtain $v_{\lambda_i} \in \Lambda_{\lambda_i}$ (since λ_i is a positive integer). In other words, the symmetric function v_{λ_i} is homogeneous of degree λ_i.

Forget that we fixed i. We thus have showed that the symmetric function v_{λ_i} is homogeneous of degree λ_i for each $i \in \{1, 2, \ldots, \ell(\lambda)\}$. Hence, the product $v_{\lambda_1} v_{\lambda_2} \cdots v_{\lambda_{\ell(\lambda)}}$ of these $\ell(\lambda)$ symmetric functions is homogeneous of degree

$$\begin{aligned} &\lambda_1 + \lambda_2 + \cdots + \lambda_{\ell(\lambda)} && (\text{since } \Lambda \text{ is a graded } \mathbf{k}\text{-algebra}) \\ &= |\lambda| && \left(\text{since } |\lambda| = \lambda_1 + \lambda_2 + \cdots + \lambda_{\ell(\lambda)}\right). \end{aligned}$$

In other words, $v_{\lambda_1} v_{\lambda_2} \cdots v_{\lambda_{\ell(\lambda)}} \in \Lambda_{|\lambda|}$. But our definition of v_λ yields $v_\lambda = v_{\lambda_1} v_{\lambda_2} \cdots v_{\lambda_{\ell(\lambda)}} \in \Lambda_{|\lambda|}$. In other words, v_λ is an element of $\Lambda_{|\lambda|}$. Qed.

But each $\lambda \in \operatorname{Par}_m$ satisfying $\lambda \neq (m)$ satisfies $a_\lambda h_\lambda \in V$ [600]. Hence,

$$\sum_{\substack{\lambda \in \operatorname{Par}_m; \\ \lambda \neq (m)}} \underbrace{a_\lambda h_\lambda}_{\in V} \in \sum_{\substack{\lambda \in \operatorname{Par}_m; \\ \lambda \neq (m)}} V \subset V \qquad (\text{since } V \text{ is a } \mathbf{k}\text{-module}).$$

Furthermore, V contains $v_1, v_2, v_3, \ldots$ (since V is the $\mathbf{k}$-subalgebra of Λ generated by $v_1, v_2, v_3, \ldots$). Thus, in particular, V contains v_m (since m is a positive integer). In other words, $v_m \in V$.

Now, (13.63.3) becomes

$$a_{(m)} h_{(m)} = \underbrace{v_m}_{\in V} - \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}_m; \\ \lambda \neq (m)}} a_\lambda h_\lambda}_{\in V} \in V - V \subset V \qquad (\text{since } V \text{ is a } \mathbf{k}\text{-module}).$$

Now, since $a_{(m)}^{-1}$ is well-defined, we have

$$h_{(m)} = a_{(m)}^{-1} \underbrace{a_{(m)} h_{(m)}}_{\in V} \in a_{(m)}^{-1} V \subset V \qquad (\text{since } V \text{ is a } \mathbf{k}\text{-module}).$$

In view of $h_{(m)} = h_m$, this rewrites as $h_m \in V$. In other words, (13.63.1) holds for $n = m$. This completes the induction step. Thus, (13.63.1) is proved by strong induction.]

Let us now draw some conclusions. We can restate (13.63.1) as follows: The elements $h_1, h_2, h_3, \ldots$ all belong to V. In other words, V contains $h_1, h_2, h_3, \ldots$.

Proposition 2.4.1 shows that the family $(h_n)_{n=1,2,\ldots}$ generates the $\mathbf{k}$-algebra $\Lambda_{\mathbf{k}}$. In other words, the family $(h_n)_{n=1,2,\ldots}$ generates the $\mathbf{k}$-algebra Λ (since $\Lambda_{\mathbf{k}} = \Lambda$). In other words, the elements $h_1, h_2, h_3, \ldots$ generate the $\mathbf{k}$-algebra Λ. Thus, the only $\mathbf{k}$-subalgebra of Λ that contains these elements $h_1, h_2, h_3, \ldots$ is the whole algebra Λ. In other words,

$$(\text{if } B \text{ is any } \mathbf{k}\text{-subalgebra of } \Lambda \text{ that contains } h_1, h_2, h_3, \ldots, \text{ then } B = \Lambda).$$

We can apply this to $B = V$ (since V is a $\mathbf{k}$-subalgebra of Λ that contains $h_1, h_2, h_3, \ldots$), and thus conclude that $V = \Lambda$. In other words, the $\mathbf{k}$-subalgebra of Λ generated by $v_1, v_2, v_3, \ldots$ is Λ (since V was defined to be the $\mathbf{k}$-subalgebra of Λ generated by $v_1, v_2, v_3, \ldots$). In other words, the elements $v_1, v_2, v_3, \ldots$ generate the

[600] *Proof.* Let $\lambda \in \operatorname{Par}_m$ satisfy $\lambda \neq (m)$. We must show that $a_\lambda h_\lambda \in V$.

Write the partition λ in the form $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ with $\ell = \ell(\lambda)$. Then, the definition of h_λ yields $h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_\ell}$. From $\lambda \in \operatorname{Par}_m$, we conclude that $m = |\lambda| = \lambda_1 + \lambda_2 + \cdots + \lambda_\ell$ (since $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$).

Assume (for the sake of contradiction) that $\ell = 1$. Then, we have $m = \lambda_1 + \lambda_2 + \cdots + \lambda_\ell = \lambda_1$ (since $\ell = 1$), so that $\lambda_1 = m$. Moreover, from $\ell = 1$, we obtain $(\lambda_1, \lambda_2, \ldots, \lambda_\ell) = (\lambda_1) = (m)$ (since $\lambda_1 = m$), and therefore $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell) = (m)$. This contradicts $\lambda \neq (m)$.

This contradiction shows that our assumption was wrong. Hence, we must have $\ell \neq 1$.

Now, let $i \in \{1, 2, \ldots, \ell\}$ be arbitrary. Then, $i \leq \ell = \ell(\lambda)$. Hence, λ_i is a positive integer.

Also, from $i \in \{1, 2, \ldots, \ell\}$, we obtain $1 \leq i \leq \ell$, so that $\ell \geq 1$. Combining this with $\ell \neq 1$, we obtain $\ell > 1$, so that $\ell \geq 2$. Hence, $2 \leq \ell = \ell(\lambda)$, so that $\lambda_2 > 0$ (by the definition of $\ell(\lambda)$).

But λ is a partition; thus, $\lambda_1 \geq \lambda_2 \geq \cdots \geq \lambda_\ell$. Hence, $\lambda_1 \geq \lambda_i$ (since $1 \leq i \leq \ell$), so that $\lambda_i \leq \lambda_1$. Also,

$$m = |\lambda| = \lambda_1 + \lambda_2 + \lambda_3 + \cdots = \lambda_1 + \underbrace{\lambda_2}_{>0} + \underbrace{(\lambda_3 + \lambda_4 + \lambda_5 + \cdots)}_{\geq 0} > \lambda_1.$$

In other words, $\lambda_1 < m$. Thus, $\lambda_i \leq \lambda_1 < m$. Hence, (13.63.2) (applied to $n = \lambda_i$) yields $h_{\lambda_i} \in V$ (since λ_i is a positive integer).

Forget that we fixed i. We thus have shown that $h_{\lambda_i} \in V$ for each $i \in \{1, 2, \ldots, \ell\}$. In other words, $h_{\lambda_1}, h_{\lambda_2}, \ldots, h_{\lambda_\ell}$ are elements of V. Thus, $h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_\ell}$ is a product of elements of V, and therefore must itself be an element of V (since V is a $\mathbf{k}$-subalgebra of Λ). In other words, $h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_\ell} \in V$. Now, $h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_\ell} \in V$. Hence, $a_\lambda \underbrace{h_\lambda}_{\in V} \in a_\lambda V \subset V$ (since V is a $\mathbf{k}$-module). Qed.

k-algebra Λ. Moreover, we have $v_n \in \Lambda_n$ for each positive integer n [601]. Thus, Exercise 2.5.22(a) shows that $v_1, v_2, v_3, \ldots$ are algebraically independent over **k**. This completes the solution to Exercise 2.5.23.

13.64. **Solution to Exercise 2.5.24.** *Solution to Exercise 2.5.24.* Corollary 2.5.17(a) says that the bases $(h_\lambda)_{\lambda \in \operatorname{Par}}$ and $(m_\lambda)_{\lambda \in \operatorname{Par}}$ of Λ are dual with respect to the Hall inner product on Λ. In other words,

$$(h_\lambda, m_\mu) = \delta_{\lambda,\mu} \qquad \text{for any } \lambda \in \operatorname{Par} \text{ and } \mu \in \operatorname{Par}. \tag{13.64.1}$$

Proposition 2.4.1 shows that the family $(h_n)_{n=1,2,\ldots}$ generates the **k**-algebra $\Lambda_{\mathbf{k}}$. In other words, the family $(h_n)_{n=1,2,\ldots}$ generates the **k**-algebra Λ (since $\Lambda_{\mathbf{k}} = \Lambda$). In other words, $h_1, h_2, h_3, \ldots$ generate the **k**-algebra Λ. Furthermore, $h_n \in \Lambda_n$ for each positive integer n. Finally, for every partition λ, the symmetric function $h_\lambda \in \Lambda$ is defined by $h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_{\ell(\lambda)}}$. Hence, Exercise 2.5.22(b) (applied to h_n and h_λ instead of v_n and v_λ) shows that the family $(h_\lambda)_{\lambda \in \operatorname{Par}}$ is a graded basis of the graded **k**-module Λ. In other words, for each $n \in \mathbb{N}$,

$$\text{the family } (h_\lambda)_{\lambda \in \operatorname{Par}_n} \text{ is a basis of the } \mathbf{k}\text{-module } \Lambda_n. \tag{13.64.2}$$

Now, let n be a positive integer. Then, $v_n \in \Lambda_n$ (by assumption) and $(n) \in \operatorname{Par}_n$ (since (n) is a partition of n). But (13.64.2) shows that the family $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the **k**-module Λ_n. Hence, this family spans Λ_n. Thus, v_n is a **k**-linear combination of the family $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ (since $v_n \in \Lambda_n$). In other words, there exists some family $(b_\lambda)_{\lambda \in \operatorname{Par}_n} \in \mathbf{k}^{\operatorname{Par}_n}$ of scalars such that $v_n = \sum_{\lambda \in \operatorname{Par}_n} b_\lambda h_\lambda$. Consider this family $(b_\lambda)_{\lambda \in \operatorname{Par}_n}$.

Now, recall that the Hall inner product has an orthonormal basis (namely, $(s_\lambda)_{\lambda \in \operatorname{Par}}$), and thus is symmetric. Therefore, every $\mu \in \operatorname{Par}_n$ satisfies

$$\begin{aligned}
(m_\mu, v_n) &= \left(\underbrace{v_n}_{= \sum_{\lambda \in \operatorname{Par}_n} b_\lambda h_\lambda}, m_\mu \right) = \left(\sum_{\lambda \in \operatorname{Par}_n} b_\lambda h_\lambda, m_\mu \right) = \sum_{\lambda \in \operatorname{Par}_n} b_\lambda \underbrace{(h_\lambda, m_\mu)}_{\substack{= \delta_{\lambda,\mu} \\ \text{(by (13.64.1))}}} \\
&\qquad \text{(since the Hall inner product is } \mathbf{k}\text{-bilinear)} \\
&= \sum_{\lambda \in \operatorname{Par}_n} b_\lambda \delta_{\lambda,\mu} = b_\mu \underbrace{\delta_{\mu,\mu}}_{\substack{=1 \\ \text{(since } \mu = \mu)}} + \sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \lambda \neq \mu}} b_\lambda \underbrace{\delta_{\lambda,\mu}}_{\substack{=0 \\ \text{(since } \lambda \neq \mu)}} \\
&\qquad \text{(here, we have split off the addend for } \lambda = \mu \text{ from the sum, since } \mu \in \operatorname{Par}_n) \\
&= b_\mu + \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \lambda \neq \mu}} b_\lambda 0}_{=0} = b_\mu.
\end{aligned}$$

[601] *Proof.* We know that $h_n \in \Lambda_n$ for each positive integer n. Furthermore, we know that the family $(h_n)_{n=1,2,\ldots}$ generates the **k**-algebra Λ; in other words, $h_1, h_2, h_3, \ldots$ generate the **k**-algebra Λ. Finally, for every partition λ, the symmetric function $h_\lambda \in \Lambda$ is defined by $h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_{\ell(\lambda)}}$. Hence, Exercise 2.5.22(b) (applied to h_n and h_λ instead of v_n and v_λ) shows that the family $(h_\lambda)_{\lambda \in \operatorname{Par}}$ is a graded basis of the graded **k**-module Λ. In other words, for each $n \in \mathbb{N}$,

$$\text{the family } (h_\lambda)_{\lambda \in \operatorname{Par}_n} \text{ is a basis of the } \mathbf{k}\text{-module } \Lambda_n. \tag{13.63.4}$$

Now, let n be a positive integer. Then, (13.63.4) shows that the family $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the **k**-module Λ_n. Hence,

$$h_\lambda \in \Lambda_n \qquad \text{for each } \lambda \in \operatorname{Par}_n. \tag{13.63.5}$$

But by assumption, we have

$$v_n = \sum_{\lambda \in \operatorname{Par}_n} a_\lambda \underbrace{h_\lambda}_{\substack{\in \Lambda_n \\ \text{(by (13.63.5))}}} \in \sum_{\lambda \in \operatorname{Par}_n} a_\lambda \Lambda_n \subset \Lambda_n \qquad \text{(since } \Lambda_n \text{ is a } \mathbf{k}\text{-module)}.$$

Qed.

Renaming μ as λ in this statement, we obtain the following: Every $\lambda \in \operatorname{Par}_n$ satisfies $(m_\lambda, v_n) = b_\lambda$. Hence, every $\lambda \in \operatorname{Par}_n$ satisfies

$$b_\lambda = (m_\lambda, v_n) = \left(m_\lambda, v_{|\lambda|}\right) \tag{13.64.3}$$

(since $n = |\lambda|$ (because $\lambda \in \operatorname{Par}_n$ and thus $|\lambda| = n$)). Now,

$$v_n = \sum_{\lambda \in \operatorname{Par}_n} \underbrace{b_\lambda}_{\substack{=\left(m_\lambda, v_{|\lambda|}\right) \\ \text{(by (13.64.3))}}} h_\lambda = \sum_{\lambda \in \operatorname{Par}_n} \left(m_\lambda, v_{|\lambda|}\right) h_\lambda.$$

Forget that we fixed n. Thus, we have showed that each positive integer n satisfies $v_n = \sum_{\lambda \in \operatorname{Par}_n} \left(m_\lambda, v_{|\lambda|}\right) h_\lambda$. Moreover, the element $\left(m_{(n)}, v_{|(n)|}\right) \in \mathbf{k}$ is invertible for each positive integer n [602]. Hence, Exercise 2.5.23 (applied to $a_\lambda = \left(m_\lambda, v_{|\lambda|}\right)$) yields that the elements $v_1, v_2, v_3, \ldots$ generate the $\mathbf{k}$-algebra Λ and are algebraically independent over $\mathbf{k}$. This solves Exercise 2.5.24.

13.65. **Solution to Exercise 2.5.25.** *Solution to Exercise 2.5.25.* Corollary 2.5.17(a) yields that $(h_\lambda)_{\lambda \in \operatorname{Par}}$ and $(m_\lambda)_{\lambda \in \operatorname{Par}}$ are dual bases with respect to the Hall inner product on Λ.

Recall the following fundamental fact from linear algebra: If $\mathbf{k}$ is a commutative ring, if A is a $\mathbf{k}$-module, if $(\cdot, \cdot) : A \times A \to \mathbf{k}$ is a symmetric $\mathbf{k}$-bilinear form on A, and if $(u_\lambda)_{\lambda \in L}$ and $(v_\lambda)_{\lambda \in L}$ are two $\mathbf{k}$-bases of A which are dual to each other with respect to the form $(\cdot, \cdot)$ (where L is some indexing set), then every $a \in A$ satisfies

$$a = \sum_{\lambda \in L} (u_\lambda, a)\, v_\lambda.$$

We can apply this fact to $A = \Lambda$, $L = \operatorname{Par}$, $(u_\lambda)_{\lambda \in L} = (h_\lambda)_{\lambda \in \operatorname{Par}}$ and $(v_\lambda)_{\lambda \in L} = (m_\lambda)_{\lambda \in \operatorname{Par}}$ (since the bases $(h_\lambda)_{\lambda \in \operatorname{Par}}$ and $(m_\lambda)_{\lambda \in \operatorname{Par}}$ of Λ are dual to each other with respect to the Hall inner product $(\cdot, \cdot)$). As a result, we obtain that every $a \in \Lambda$ satisfies

$$a = \sum_{\lambda \in \operatorname{Par}} (h_\lambda, a)\, m_\lambda. \tag{13.65.1}$$

Now, let WC denote the set of all weak compositions. Thus, $\beta \in \mathrm{WC}$. Recall (from Section 2.1) the finitary symmetric group $\mathfrak{S}_{(\infty)}$ and its action on the set WC of all weak compositions. Applying the equality (13.65.1) to $a = f$, we obtain

$$\begin{aligned} f &= \sum_{\lambda \in \operatorname{Par}} (h_\lambda, f) \underbrace{m_\lambda}_{\substack{= \sum_{\alpha \in \mathfrak{S}_{(\infty)} \lambda} \mathbf{x}^\alpha \\ \text{(by (2.1.1))}}} = \sum_{\lambda \in \operatorname{Par}} (h_\lambda, f) \sum_{\alpha \in \mathfrak{S}_{(\infty)} \lambda} \mathbf{x}^\alpha \\ &= \underbrace{\sum_{\lambda \in \operatorname{Par}} \sum_{\alpha \in \mathfrak{S}_{(\infty)} \lambda}}_{= \sum_{\alpha \in \mathrm{WC}} \sum_{\substack{\lambda \in \operatorname{Par}; \\ \alpha \in \mathfrak{S}_{(\infty)} \lambda}}} (h_\lambda, f)\, \mathbf{x}^\alpha = \sum_{\alpha \in \mathrm{WC}} \sum_{\substack{\lambda \in \operatorname{Par}; \\ \alpha \in \mathfrak{S}_{(\infty)} \lambda}} (h_\lambda, f)\, \mathbf{x}^\alpha. \end{aligned}$$

Hence,

$$\begin{aligned} \left(\text{the coefficient of } \mathbf{x}^\beta \text{ in } f\right) &= \left(\text{the coefficient of } \mathbf{x}^\beta \text{ in } \sum_{\alpha \in \mathrm{WC}} \sum_{\substack{\lambda \in \operatorname{Par}; \\ \alpha \in \mathfrak{S}_{(\infty)} \lambda}} (h_\lambda, f)\, \mathbf{x}^\alpha \right) \\ &= \sum_{\substack{\lambda \in \operatorname{Par}; \\ \beta \in \mathfrak{S}_{(\infty)} \lambda}} (h_\lambda, f)\,. \end{aligned} \tag{13.65.2}$$

[602] *Proof.* We have assumed that $(p_n, v_n) \in \mathbf{k}$ is invertible for each positive integer n. In other words, $\left(m_{(n)}, v_{|(n)|}\right) \in \mathbf{k}$ is invertible for each positive integer n (since each positive integer n satisfies $m_{(n)} = p_n$ and $|(n)| = n$).

Recall that μ is the partition consisting of the nonzero entries of β (sorted in decreasing order). Hence, the partition μ has the same nonzero entries as the weak composition β (just possibly in a different order). Thus, the partition β can be obtained by rearranging the entries of the weak composition μ. More precisely, we can transform μ into β by rearranging finitely many entries of μ [603]. In other words, there exists a permutation $\sigma \in \mathfrak{S}_{(\infty)}$ such that $\beta = \sigma(\mu)$ (because rearranging finitely many entries of a weak composition is tantamount to applying a permutation in $\mathfrak{S}_{(\infty)}$ to it). In other words, $\beta \in \mathfrak{S}_{(\infty)}\mu$. Hence, μ is a $\lambda \in \operatorname{Par}$ such that $\beta \in \mathfrak{S}_{(\infty)}\lambda$.

On the other hand, recall that every weak composition α lies in the $\mathfrak{S}_{(\infty)}$-orbit of a unique partition λ. In other words, for every weak composition α, there is a unique partition λ such that $\alpha \in \mathfrak{S}_{(\infty)}\lambda$. Applying this to $\alpha = \beta$, we conclude that there is a unique partition λ such that $\beta \in \mathfrak{S}_{(\infty)}\lambda$. In other words, there is a unique $\lambda \in \operatorname{Par}$ such that $\beta \in \mathfrak{S}_{(\infty)}\lambda$. This unique λ must be μ (since μ is a $\lambda \in \operatorname{Par}$ such that $\beta \in \mathfrak{S}_{(\infty)}\lambda$).

So we know that there is a unique $\lambda \in \operatorname{Par}$ such that $\beta \in \mathfrak{S}_{(\infty)}\lambda$, and this unique λ is μ. Hence, the sum $\sum\limits_{\substack{\lambda \in \operatorname{Par};\\ \beta \in \mathfrak{S}_{(\infty)}\lambda}} (h_\lambda, f)$ has exactly one addend, namely the addend for $\lambda = \mu$. Thus, this sum simplifies as follows: $\sum\limits_{\substack{\lambda \in \operatorname{Par};\\ \beta \in \mathfrak{S}_{(\infty)}\lambda}} (h_\lambda, f) = (h_\mu, f)$.

Hence, (13.65.2) becomes

$$\left(\text{the coefficient of } \mathbf{x}^\beta \text{ in } f\right) = \sum_{\substack{\lambda \in \operatorname{Par};\\ \beta \in \mathfrak{S}_{(\infty)}\lambda}} (h_\lambda, f) = (h_\mu, f).$$

Combining this with

$$(f, h_\mu) = (h_\mu, f) \qquad \text{(by Exercise 2.5.13(c), applied to } g = h_\mu\text{)},$$

we obtain

$$(f, h_\mu) = (h_\mu, f) = \left(\text{the coefficient of } \mathbf{x}^\beta \text{ in } f\right).$$

This solves Exercise 2.5.25.

13.66. **Solution to Exercise 2.5.26.** *Solution to Exercise 2.5.26.* Let us first prove three simple claims:

Claim 1: For every $\lambda \in \operatorname{Par}$, we have $p_\lambda \in \Lambda_{|\lambda|}$.

[*Proof of Claim 1:* Let $n = |\lambda|$. Thus, $\lambda \in \operatorname{Par}_n$ (since $\lambda \in \operatorname{Par}$). Hence, we can show (just as in the solution to Exercise 2.2.13(k)) that $p_\lambda \in \Lambda_n$. In view of $n = |\lambda|$, this rewrites as $p_\lambda \in \Lambda_{|\lambda|}$. This proves Claim 1.]

Claim 2: Let $n \in \mathbb{N}$ and $\lambda \in \operatorname{Par}_n$. Then, $(p_\lambda, h_n) = 1$.

[*Proof of Claim 2:* We have $|\lambda| = n$ (since $\lambda \in \operatorname{Par}_n$). Claim 1 yields $p_\lambda \in \Lambda_{|\lambda|} = \Lambda_n$ (since $|\lambda| = n$). Hence, Exercise 2.5.13(b) (applied to $f = p_\lambda$) yields $(h_n, p_\lambda) = p_\lambda(1)$ (where $p_\lambda(1)$ is defined as in Exercise 2.1.2).

Recall that $p_\lambda(1)$ is defined to be the result of substituting $1, 0, 0, 0, \ldots$ for $x_1, x_2, x_3, \ldots$ in p_λ. In other words, $p_\lambda(1) = p_\lambda(1, 0, 0, 0, \ldots)$.

Now, write the partition λ as $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$, where $\ell = \ell(\lambda)$. Then, the definition of p_λ yields $p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_\ell} = \prod_{i=1}^{\ell} p_{\lambda_i}$. Substituting $1, 0, 0, 0, \ldots$ for $x_1, x_2, x_3, \ldots$ on both sides of this equality, we obtain

$$p_\lambda(1, 0, 0, 0, \ldots) = \prod_{i=1}^{\ell} \underbrace{p_{\lambda_i}(1, 0, 0, 0, \ldots)}_{\substack{= 1^{\lambda_i} + 0^{\lambda_i} + 0^{\lambda_i} + 0^{\lambda_i} + \cdots \\ (\text{since } p_{\lambda_i} = x_1^{\lambda_i} + x_2^{\lambda_i} + x_3^{\lambda_i} + \cdots)}} = \prod_{i=1}^{\ell} \underbrace{\left(1^{\lambda_i} + 0^{\lambda_i} + 0^{\lambda_i} + 0^{\lambda_i} + \cdots\right)}_{\substack{= 1 + 0 + 0 + 0 + \cdots \\ (\text{since } 1^{\lambda_i} = 1 \text{ and } 0^{\lambda_i} = 0 \\ (\text{because } \lambda_i \text{ is positive (since } i \leq \ell = \ell(\lambda))))}}$$

$$= \prod_{i=1}^{\ell} \underbrace{(1 + 0 + 0 + 0 + \cdots)}_{=1} = 1.$$

[603] Indeed, there is an $i \in \{1, 2, 3, \ldots\}$ such that $\beta_{i+1} = \beta_{i+2} = \beta_{i+3} = \cdots = 0$ and $\mu_{i+1} = \mu_{i+2} = \mu_{i+3} = \cdots = 0$ (since β and μ are weak compositions). We only need to rearrange the first i entries in order to transform μ into β.

Summarizing what we have proved so far, we obtain

$$(h_n, p_\lambda) = p_\lambda (1) = p_\lambda (1, 0, 0, 0, \ldots) = 1.$$

But Exercise 2.5.13(c) (applied to $f = p_\lambda$ and $g = h_n$) yields $(p_\lambda, h_n) = (h_n, p_\lambda) = 1$. This proves Claim 2.]

Claim 3: Let $n \in \mathbb{N}$ and $\lambda \in \operatorname{Par}$ be such that $\lambda \notin \operatorname{Par}_n$. Then, $(p_\lambda, h_n) = 0$.

[*Proof of Claim 3:* We have $|\lambda| \neq n$ (since $\lambda \in \operatorname{Par}$ but $\lambda \notin \operatorname{Par}_n$). Therefore, $|\lambda|$ and n are two distinct nonnegative integers. Moreover, $p_\lambda \in \Lambda_{|\lambda|}$ (by Claim 1) and $h_n \in \Lambda_n$. Hence, Exercise 2.5.13(a) (applied to $|\lambda|$, n, p_λ and h_n instead of n, m, f and g) yields $(p_\lambda, h_n) = 0$. This proves Claim 3.]

Corollary 2.5.17(b) yields that $(p_\lambda)_{\lambda\in\operatorname{Par}}$ and $\left(z_\lambda^{-1} p_\lambda\right)_{\lambda\in\operatorname{Par}}$ are dual bases with respect to the Hall inner product on Λ. Recall the following fundamental fact from linear algebra: If $\mathbf{k}$ is a commutative ring, if A is a $\mathbf{k}$-module, if $(\cdot, \cdot) : A \times A \to \mathbf{k}$ is a symmetric $\mathbf{k}$-bilinear form on A, and if $(u_\lambda)_{\lambda\in L}$ and $(v_\lambda)_{\lambda\in L}$ are two $\mathbf{k}$-bases of A which are dual to each other with respect to the form $(\cdot, \cdot)$ (where L is some indexing set), then every $a \in A$ satisfies

$$a = \sum_{\lambda\in L} (u_\lambda, a) v_\lambda.$$

We can apply this fact to $A = \Lambda$, $L = \operatorname{Par}$, $(u_\lambda)_{\lambda\in L} = (p_\lambda)_{\lambda\in\operatorname{Par}}$ and $(v_\lambda)_{\lambda\in L} = \left(z_\lambda^{-1} p_\lambda\right)_{\lambda\in\operatorname{Par}}$ (since the bases $(p_\lambda)_{\lambda\in\operatorname{Par}}$ and $\left(z_\lambda^{-1} p_\lambda\right)_{\lambda\in\operatorname{Par}}$ of Λ are dual to each other with respect to the Hall inner product $(\cdot, \cdot)$). As a result, we obtain that every $a \in \Lambda$ satisfies

$$a = \sum_{\lambda\in\operatorname{Par}} (p_\lambda, a) z_\lambda^{-1} p_\lambda. \tag{13.66.1}$$

Now, let $n \in \mathbb{N}$. Applying (13.66.1) to $a = h_n$, we find

$$\begin{aligned} h_n &= \sum_{\lambda\in\operatorname{Par}} (p_\lambda, h_n) z_\lambda^{-1} p_\lambda = \underbrace{\sum_{\substack{\lambda\in\operatorname{Par};\\ \lambda\in\operatorname{Par}_n}}}_{\substack{=\sum_{\lambda\in\operatorname{Par}_n}\\ (\text{since } \operatorname{Par}_n\subset\operatorname{Par})}} \underbrace{(p_\lambda, h_n)}_{\substack{=1\\ (\text{by Claim 2})}} z_\lambda^{-1} p_\lambda + \sum_{\substack{\lambda\in\operatorname{Par};\\ \lambda\notin\operatorname{Par}_n}} \underbrace{(p_\lambda, h_n)}_{\substack{=0\\ (\text{by Claim 3})}} z_\lambda^{-1} p_\lambda \\ &\qquad \left(\begin{array}{c} \text{since each } \lambda \in \operatorname{Par} \text{ satisfies either } \lambda \in \operatorname{Par}_n \text{ or } \lambda \notin \operatorname{Par}_n \\ \text{(but not both at the same time)} \end{array}\right) \\ &= \sum_{\lambda\in\operatorname{Par}_n} z_\lambda^{-1} p_\lambda + \underbrace{\sum_{\substack{\lambda\in\operatorname{Par};\\ \lambda\notin\operatorname{Par}_n}} 0 z_\lambda^{-1} p_\lambda}_{=0} = \sum_{\lambda\in\operatorname{Par}_n} z_\lambda^{-1} p_\lambda. \end{aligned}$$

This proves (2.5.17).

Recall the map $\omega : \Lambda \to \Lambda$ introduced in Definition 2.4.2. Applying this map ω to both sides of the equality (2.5.17), we obtain

$$\begin{aligned} \omega(h_n) &= \omega\left(\sum_{\lambda\in\operatorname{Par}_n} z_\lambda^{-1} p_\lambda\right) = \sum_{\lambda\in\operatorname{Par}_n} z_\lambda^{-1} \underbrace{\omega(p_\lambda)}_{\substack{=(-1)^{|\lambda|-\ell(\lambda)} p_\lambda\\ (\text{by } (2.4.14))}} \qquad (\text{since the map } \omega \text{ is } \mathbf{k}\text{-linear}) \\ &= \sum_{\lambda\in\operatorname{Par}_n} \underbrace{z_\lambda^{-1} (-1)^{|\lambda|-\ell(\lambda)}}_{=(-1)^{|\lambda|-\ell(\lambda)} z_\lambda^{-1}} p_\lambda = \sum_{\lambda\in\operatorname{Par}_n} (-1)^{|\lambda|-\ell(\lambda)} z_\lambda^{-1} p_\lambda. \end{aligned}$$

But Proposition 2.4.3(b) yields $\omega(h_n) = e_n$. Comparing these two equalities, we obtain

$$e_n = \sum_{\lambda\in\operatorname{Par}_n} (-1)^{|\lambda|-\ell(\lambda)} z_\lambda^{-1} p_\lambda.$$

This proves (2.5.18). Thus, the solution to Exercise 2.5.26 is complete.

13.67. **Solution to Exercise 2.7.5.** *Solution to Exercise 2.7.5.* We recall that the cells of λ/μ are the cells $(p,q) \in \{1,2,3,...\}^2$ satisfying $\mu_p < q \leq \lambda_p$.

(a) In order to solve Exercise 2.7.5(a), we need to prove the following two claims:

$$\text{(if } \lambda/\mu \text{ is a horizontal strip, then every } i \in \{1,2,3,...\} \text{ satisfies } \mu_i \geq \lambda_{i+1}) \tag{13.67.1}$$

and

$$\text{(if every } i \in \{1,2,3,...\} \text{ satisfies } \mu_i \geq \lambda_{i+1}, \text{ then } \lambda/\mu \text{ is a horizontal strip)}. \tag{13.67.2}$$

Proof of (13.67.1)*:* Assume that λ/μ is a horizontal strip. In other words, no two cells of λ/μ lie in the same column.

Let $i \in \{1,2,3,...\}$. Assume (for the sake of contradiction) that $\mu_i < \lambda_{i+1}$. Hence, $\lambda_{i+1} > \mu_i \geq 0$. Also, $\mu \subseteq \lambda$ yields $\mu_i \leq \lambda_i$. Hence, $\mu_{i+1} \leq \mu_i < \lambda_{i+1}$. Now, (i, λ_{i+1}) is a cell of λ/μ (since $\mu_i < \lambda_{i+1} \leq \lambda_i$). Also, $(i+1, \lambda_{i+1})$ is a cell of λ/μ (since $\mu_{i+1} < \lambda_{i+1} \leq \lambda_{i+1}$). Thus, (i, λ_{i+1}) and $(i+1, \lambda_{i+1})$ are two cells of λ/μ lying in the same column. This contradicts the fact that no two cells of λ/μ lie in the same column. This contradiction shows that our assumption (that $\mu_i < \lambda_{i+1}$) was wrong. Hence, $\mu_i \geq \lambda_{i+1}$. This proves (13.67.1).

Proof of (13.67.2)*:* Assume that every $i \in \{1,2,3,...\}$ satisfies $\mu_i \geq \lambda_{i+1}$.

Now, let us (for the sake of contradiction) assume that there exist two distinct cells of λ/μ which lie in the same column. Let c and d be two such cells. Thus, c and d are two distinct cells of λ/μ which lie in the same column.

Write c and d in the forms $c = (p_c, q_c)$ and $d = (p_d, q_d)$ for some positive integers p_c, q_c, p_d, q_d. We have $\mu_{p_c} < q_c \leq \lambda_{p_c}$ (since $(p_c, q_c) = c$ is a cell of λ/μ) and $\mu_{p_d} < q_d \leq \lambda_{p_d}$ (similarly). The cells c and d lie in the same column; in other words, $q_c = q_d$ (because the cell $c = (p_c, q_c)$ lies in column q_c, and the cell $d = (p_d, q_d)$ lies in column q_d).

Our situation so far is symmetric with respect to interchanging c with d. Hence, we can WLOG assume that $p_c \leq p_d$ (because otherwise, we can switch c with d). Assume this.

If we had $p_c = p_d$, then we would have $c = \left(\underbrace{p_c}_{=p_d}, \underbrace{q_c}_{=q_d}\right) = (p_d, q_d) = d$, which would contradict the fact that c and d are distinct. Hence, we cannot have $p_c = p_d$. Thus, we have $p_c \neq p_d$. Combined with $p_c \leq p_d$, this yields $p_c < p_d$. Thus, $p_c \leq p_d - 1$ (since p_c and p_d are integers), so that $p_c + 1 \leq p_d$.

Since λ is a partition, we have $\lambda_u \geq \lambda_v$ for any positive integers u and v satisfying $u \leq v$. Applying this to $u = p_c + 1$ and $v = p_d$, we obtain $\lambda_{p_c+1} \geq \lambda_{p_d}$ (since $p_c + 1 \leq p_d$). But recall that every $i \in \{1,2,3,...\}$ satisfies $\mu_i \geq \lambda_{i+1}$. Applying this to $i = p_c$, we obtain $\mu_{p_c} \geq \lambda_{p_c+1}$. Now, recall that $\mu_{p_c} < q_c$, so that $q_c > \mu_{p_c} \geq \lambda_{p_c+1} \geq \lambda_{p_d} \geq q_d$ (since $q_d \leq \lambda_{p_d}$). This contradicts $q_c = q_d$. This contradiction shows that our assumption (that there exist two distinct cells of λ/μ which lie in the same column) was wrong. Hence, no two cells of λ/μ lie in the same column. In other words, λ/μ is a horizontal strip. This proves (13.67.2).

Now, both (13.67.1) and (13.67.2) are proven. Thus, Exercise 2.7.5(a) is solved.

(b) We have the following equivalence of statements:

$$\begin{aligned}
& (\lambda/\mu \text{ is a vertical strip}) \\
\Longleftrightarrow\ & (\text{no two cells of } \lambda/\mu \text{ lie in the same row}) \qquad (\text{by the definition of a ``vertical strip''}) \\
\Longleftrightarrow\ & (\text{for every } i \in \{1,2,3,\ldots\}, \text{ no two cells of } \lambda/\mu \text{ lie in row } i) \\
\Longleftrightarrow\ & \left(\text{for every } i \in \{1,2,3,\ldots\}, \underbrace{\text{the number of cells of } \lambda/\mu \text{ in row } i}_{=\lambda_i - \mu_i} \text{ is } \leq 1\right) \\
\Longleftrightarrow\ & (\text{for every } i \in \{1,2,3,\ldots\}, \text{ we have } \lambda_i - \mu_i \leq 1) \\
\Longleftrightarrow\ & (\text{for every } i \in \{1,2,3,\ldots\}, \text{ we have } \lambda_i \leq \mu_i + 1).
\end{aligned}$$

This solves Exercise 2.7.5(b).

13.68. **Solution to Exercise 2.7.6.** *Solution to Exercise 2.7.6.* (a) We use the notation $f(a_1, a_2, \ldots, a_k)$ defined in Exercise 2.1.2 whenever $a_1, a_2, \ldots, a_k$ are elements of a commutative $\mathbf{k}$-algebra A and $f \in R(\mathbf{x})$. In particular, $f(1)$ is a well-defined element of $\mathbf{k}$ for every $f \in R(\mathbf{x})$. Every $f \in R(\mathbf{x})$ satisfies

$$f(1) = (\text{the result of substituting } 1, 0, 0, 0, \ldots \text{ for } x_1, x_2, x_3, \ldots \text{ in } f). \tag{13.68.1}$$

We have $s_{\lambda/\mu} = \sum_T \mathbf{x}^{\mathrm{cont}(T)}$, where T runs through all column-strict tableaux of shape λ/μ. In other words, $s_{\lambda/\mu} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\mathrm{cont}(T)}$. Hence,

$$\begin{aligned} s_{\lambda/\mu}(1) &= \left(\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\mathrm{cont}(T)} \right)(1) \\ &= \left(\text{the result of substituting } 1, 0, 0, 0, \ldots \text{ for } x_1, x_2, x_3, \ldots \text{ in } \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\mathrm{cont}(T)} \right) \end{aligned} \tag{13.68.2}$$

(by (13.68.1)).

But the substitution $1, 0, 0, 0, \ldots$ for $x_1, x_2, x_3, \ldots$ has the following effect on any given monomial $\mathbf{x}^\alpha$:

- if none of the indeterminates $x_2, x_3, x_4, \ldots$ occur in this monomial $\mathbf{x}^\alpha$, then the monomial $\mathbf{x}^\alpha$ goes to 1;
- otherwise, the monomial $\mathbf{x}^\alpha$ goes to 0.

Hence, applying this substitution to $\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\mathrm{cont}(T)}$ yields a sum of 1's over all column-strict tableaux T of shape λ/μ having the property that none of the indeterminates $x_2, x_3, x_4, \ldots$ occur in this monomial $\mathbf{x}^{\mathrm{cont}(T)}$. In other words,

$$\begin{aligned} &\left(\text{the result of substituting } 1, 0, 0, 0, \ldots \text{ for } x_1, x_2, x_3, \ldots \text{ in } \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\mu}} \mathbf{x}^{\mathrm{cont}(T)} \right) \\ &= \sum_{\substack{T \text{ is a column-strict tableau of shape } \lambda/\mu; \\ \text{none of the indeterminates } x_2, x_3, x_4, \ldots \\ \text{occur in the monomial } \mathbf{x}^{\mathrm{cont}(T)}}} 1. \end{aligned}$$

Therefore, (13.68.2) rewrites as

$$s_{\lambda/\mu}(1) = \sum_{\substack{T \text{ is a column-strict tableau of shape } \lambda/\mu; \\ \text{none of the indeterminates } x_2, x_3, x_4, \ldots \\ \text{occur in the monomial } \mathbf{x}^{\mathrm{cont}(T)}}} 1.$$

This rewrites as

$$s_{\lambda/\mu}(1) = \sum_{\substack{T \text{ is a column-strict tableau of shape } \lambda/\mu; \\ \text{all entries of } T \text{ are } 1}} 1 \tag{13.68.3}$$

(because for a column-strict tableau T, saying that none of the indeterminates $x_2, x_3, x_4, \ldots$ occur in the monomial $\mathbf{x}^{\mathrm{cont}(T)}$ is equivalent to saying that all entries of T are 1).

In order to solve Exercise 2.7.6(a), we need to prove the following two statements:

$$\left(\text{if } \lambda/\mu \text{ is a horizontal } n\text{-strip, then } \left(h_n, s_{\lambda/\mu}\right) = 1 \right) \tag{13.68.4}$$

and

$$\left(\text{if } \lambda/\mu \text{ is not a horizontal } n\text{-strip, then } \left(h_n, s_{\lambda/\mu}\right) = 0 \right). \tag{13.68.5}$$

Proof of (13.68.4)*:* Assume that λ/μ is a horizontal n-strip. Thus, in particular, we have $|\lambda/\mu| = n$. Hence, $s_{\lambda/\mu} \in \Lambda_{|\lambda/\mu|} = \Lambda_n$ (since $|\lambda/\mu| = n$). Thus, Exercise 2.5.13(b) (applied to $f = s_{\lambda/\mu}$) yields

$$(13.68.6) \qquad \left(h_n, s_{\lambda/\mu}\right) = s_{\lambda/\mu}(1) = \sum_{\substack{T \text{ is a column-strict tableau of shape } \lambda/\mu; \\ \text{all entries of } T \text{ are } 1}} 1 \qquad \text{(by (13.68.3))}.$$

Recall that λ/μ is a horizontal n-strip, therefore a horizontal strip. In other words, no two cells of λ/μ lie in the same column. Hence, if we fill every cell of the Ferrers diagram of λ/μ with a 1, we obtain a column-strict tableau T of shape λ/μ having the property that all entries of T are 1. Therefore, such a tableau exists. It is also clearly unique (because requiring that all entries be 1 does not leave any freedom in choosing the entries). Therefore, there exists exactly one such tableau. This shows that the sum on the right hand side of (13.68.6) has exactly one addend, and therefore equals 1 (since the addend is 1). Hence, (13.68.6) rewrites as $\left(h_n, s_{\lambda/\mu}\right) = 1$, and thus (13.68.4) is proven.

Proof of (13.68.5)*:* Assume that λ/μ is not a horizontal n-strip. We need to show that $\left(h_n, s_{\lambda/\mu}\right) = 0$.

If $|\lambda/\mu| \neq n$, then Exercise 2.5.13(a) (applied to $m = |\lambda/\mu|$, $f = h_n$ and $g = s_{\lambda/\mu}$) yields $\left(h_n, s_{\lambda/\mu}\right) = 0$ (since $h_n \in \Lambda_n$ and $s_{\lambda/\mu} \in \Lambda_{|\lambda/\mu|}$). Thus, $\left(h_n, s_{\lambda/\mu}\right) = 0$ is proven if $|\lambda/\mu| \neq n$. Hence, for the rest of the proof of $\left(h_n, s_{\lambda/\mu}\right) = 0$, we WLOG assume that we don't have $|\lambda/\mu| \neq n$. Thus, $|\lambda/\mu| = n$. We can thus prove (13.68.6) just as we did before (in the proof of (13.68.4)).

But if λ/μ were a horizontal strip, then λ/μ would be a horizontal n-strip (since $|\lambda/\mu| = n$), which would contradict our assumption that λ/μ is not a horizontal n-strip. Hence, λ/μ cannot be a horizontal strip. As a consequence, there must be two cells of λ/μ which lie in the same column. If T is a column-strict tableau of shape λ/μ, then these two cells must be filled with two different entries in T (because the entries of a column-strict tableau are strictly increasing top-to-bottom down columns, and hence all entries in any given column must be distinct), which is impossible if all entries of T are to be 1. Therefore, there exists no column-strict tableau T of shape λ/μ such that all entries of T are 1. Hence, the sum on the right hand side of (13.68.6) is empty, and therefore equals 0. So (13.68.6) rewrites as $\left(h_n, s_{\lambda/\mu}\right) = 0$, and thus (13.68.5) is proven.

Now that both (13.68.4) and (13.68.5) are proven, Exercise 2.7.6(a) is solved.

(b) Notice first that

$$(13.68.7) \qquad \left(h_n, s_{\lambda/\mu}\right) = c^{\lambda}_{\mu,(n)} \qquad \text{for every } n \in \mathbb{N},\ \lambda \in \operatorname{Par} \text{ and } \mu \in \operatorname{Par}.$$

[604]

Recall that any two partitions μ and ν satisfy

$$(13.68.8) \qquad s_\mu s_\nu = \sum_{\lambda \in \operatorname{Par}} c^{\lambda}_{\mu,\nu} s_\lambda = \sum_{\tau \in \operatorname{Par}} c^{\tau}_{\mu,\nu} s_\tau$$

(here, we renamed the summation index λ as τ).

[604] *Proof.* Let $n \in \mathbb{N}$, $\lambda \in \operatorname{Par}$ and $\mu \in \operatorname{Par}$. From Remark 2.5.9, we know that $s_{\lambda/\mu} = \sum_\nu c^{\lambda}_{\mu,\nu} s_\nu$, where the sum is over all $\nu \in \operatorname{Par}$. Thus, for every given partition τ, the s_τ-coordinate of $s_{\lambda/\mu}$ in the basis $\left(s_\nu\right)_{\nu \in \operatorname{Par}}$ of Λ equals $c^{\lambda}_{\mu,\tau}$. But since $\left(s_\nu\right)_{\nu \in \operatorname{Par}}$ is an orthonormal basis of the $\mathbf{k}$-module Λ with respect to the Hall inner product, this s_τ-coordinate also equals $\left(s_\tau, s_{\lambda/\mu}\right)$. Comparing these two expressions for this s_τ-coordinate, we obtain $c^{\lambda}_{\mu,\tau} = \left(s_\tau, s_{\lambda/\mu}\right)$. Applying this to $\tau = (n)$, we obtain $c^{\lambda}_{\mu,(n)} = \left(\underbrace{s_{(n)}}_{=h_n}, s_{\lambda/\mu}\right) = \left(h_n, s_{\lambda/\mu}\right)$, which proves (13.68.7).

Let $n \in \mathbb{N}$. Let λ be a partition. We have $s_{(n)} = h_n$, so that $h_n = s_{(n)}$. Now,

$$s_\lambda \underbrace{h_n}_{=s_{(n)}} = s_\lambda s_{(n)} = \sum_{\tau \in \operatorname{Par}} \underbrace{c^\tau_{\lambda,(n)}}_{\substack{=\left(h_n, s_{\tau/\lambda}\right) \\ \text{(because (13.68.7) (applied to } \tau \\ \text{and } \lambda \text{ instead of } \lambda \text{ and } \mu\text{) yields} \\ \left(h_n, s_{\tau/\lambda}\right) = c^\tau_{\lambda,(n)})}} s_\tau \qquad \text{(by (13.68.8), applied to } \mu = \lambda \text{ and } \nu = (n))$$

$$= \sum_{\tau \in \operatorname{Par}} \left(h_n, s_{\tau/\lambda}\right) s_\tau = \sum_{\substack{\tau \in \operatorname{Par}; \\ \lambda \subseteq \tau}} \left(h_n, s_{\tau/\lambda}\right) s_\tau$$

$$\left(\begin{array}{c} \text{here, we have ridden the sum of all its addends in which } \lambda \not\subseteq \tau; \\ \text{these addends were zero (because if } \lambda \not\subseteq \tau \text{, then } \left(h_n, \underbrace{s_{\tau/\lambda}}_{=0}\right) s_\tau = 0) \end{array}\right)$$

$$= \sum_{\substack{\tau \in \operatorname{Par}; \\ \lambda \subseteq \tau; \\ \tau/\lambda \text{ is a horizontal } n\text{-strip}}} \underbrace{\left(h_n, s_{\tau/\lambda}\right)}_{\substack{=1 \\ \text{(by (13.68.4), applied} \\ \text{to } \tau \text{ and } \lambda \text{ instead of } \lambda \text{ and } \mu)}} s_\tau + \sum_{\substack{\tau \in \operatorname{Par}; \\ \lambda \subseteq \tau; \\ \tau/\lambda \text{ is not a horizontal } n\text{-strip}}} \underbrace{\left(h_n, s_{\tau/\lambda}\right)}_{\substack{=0 \\ \text{(by (13.68.5), applied} \\ \text{to } \tau \text{ and } \lambda \text{ instead of } \lambda \text{ and } \mu)}} s_\tau$$

$$= \sum_{\substack{\tau \in \operatorname{Par}; \\ \lambda \subseteq \tau; \\ \tau/\lambda \text{ is a horizontal } n\text{-strip}}} s_\tau + \underbrace{\sum_{\substack{\tau \in \operatorname{Par}; \\ \lambda \subseteq \tau; \\ \tau/\lambda \text{ is not a horizontal } n\text{-strip}}} 0 s_\tau}_{=0}$$

$$= \sum_{\substack{\tau \in \operatorname{Par}; \\ \lambda \subseteq \tau; \\ \tau/\lambda \text{ is a horizontal } n\text{-strip}}} s_\tau = \sum_{\substack{\lambda^+ \in \operatorname{Par}; \\ \lambda \subseteq \lambda^+; \\ \lambda^+/\lambda \text{ is a horizontal } n\text{-strip}}} s_{\lambda^+}$$

$$\left(\text{here, we renamed the summation index } \tau \text{ as } \lambda^+\right)$$

$$= \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{\lambda^+}.$$

This proves (2.7.1). Thus, Exercise 2.7.6(b) is solved.

13.69. **Solution to Exercise 2.7.7.** *Solution to Exercise 2.7.7.* Let us use the notations introduced in the proof of Theorem 2.5.1. In particular, we use the words "letter" and "positive integer" as synonyms.

We shall use the following lemma:

Lemma 13.69.1. *Let P be a column-strict tableau, and let j and j' be two letters. Applying RS-insertion to the tableau P and the letter j yields a new column-strict tableau P' and a corner cell c. Applying RS-insertion to the tableau P' and the letter j' yields a new column-strict tableau P'' and a corner cell c'.*

(a) *Assume that $j \leq j'$. Then, the cell c' is in the same row as the cell c or in a row further up; it is also in a column further right than c.*

(b) *Assume instead that $j > j'$. Then, the cell c' is in a row further down than the cell c; it is also in the same column as c or in a column further left.*

Lemma 13.69.1 is part of the Row bumping lemma that appeared in our proof of Theorem 2.5.1.

We shall first concentrate on proving (2.7.1).

Alternative proof of (2.7.1). Let λ be a partition, and let $n \in \mathbb{N}$. The definition of s_λ yields

$$s_\lambda = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(T)}.$$

The definition of h_n yields

$$h_n = \sum_{i_1 \leq i_2 \leq \cdots \leq i_n} x_{i_1} x_{i_2} \cdots x_{i_n}. \tag{13.69.1}$$

Multiplying these two identities, we obtain

$$\begin{aligned} s_\lambda h_n &= \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(T)} \sum_{i_1 \leq i_2 \leq \cdots \leq i_n} x_{i_1} x_{i_2} \cdots x_{i_n} \\ &= \sum_{(T,(i_1,i_2,\ldots,i_n)) \in \mathbf{A}} \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n}, \qquad (13.69.2) \end{aligned}$$

where $\mathbf{A}$ is the set of all pairs $(T, (i_1, i_2, \ldots, i_n))$ of a column-strict tableau T of shape λ and an n-tuple $(i_1, i_2, \ldots, i_n)$ of positive integers satisfying $i_1 \leq i_2 \leq \cdots \leq i_n$. Consider this set $\mathbf{A}$.

On the other hand, every partition λ^+ satisfies

$$\begin{aligned} s_{\lambda^+} &= \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(T)} \qquad \left(\text{by the definition of } s_{\lambda^+}\right) \\ &= \sum_{\substack{S \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(S)} \qquad \left(\text{here, we renamed the summation index } T \text{ as } S\right). \qquad (13.69.3) \end{aligned}$$

Hence,

$$\begin{aligned} \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} \underbrace{s_{\lambda^+}}_{\substack{= \sum\limits_{\substack{S \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(S)} \\ (\text{by (13.69.3)})}} &= \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} \sum_{\substack{S \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(S)} \\ &= \sum_{(\lambda^+, S) \in \mathbf{B}} \mathbf{x}^{\operatorname{cont}(S)}, \qquad (13.69.4) \end{aligned}$$

where $\mathbf{B}$ is the set of all pairs (λ^+, S) of a partition λ^+ and a column-strict tableau S of shape λ^+ such that λ^+/λ is a horizontal n-strip. Consider this set $\mathbf{B}$.

We shall now prove that there exists a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ which has the property that

$$\mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n} = \mathbf{x}^{\operatorname{cont}(S)} \tag{13.69.5}$$

whenever some $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$ and $(\lambda^+, S) \in \mathbf{B}$ satisfy $\mathbf{i}((T, (i_1, i_2, \ldots, i_n))) = (\lambda^+, S)$. Once this will be proven, it will immediately follow that $\sum_{(T,(i_1,i_2,\ldots,i_n)) \in \mathbf{A}} \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n} = \sum_{(\lambda^+,S) \in \mathbf{B}} \mathbf{x}^{\operatorname{cont}(S)}$, and therefore (13.69.2) will become

$$s_\lambda h_n = \sum_{(T,(i_1,i_2,\ldots,i_n)) \in \mathbf{A}} \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n} = \sum_{(\lambda^+,S) \in \mathbf{B}} \mathbf{x}^{\operatorname{cont}(S)} = \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{\lambda^+} \qquad \left(\text{by (13.69.4)}\right),$$

and thus (2.7.1) will be proven. Hence, in order to complete the proof of (2.7.1), it is enough to prove that there exists a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ which has the property (13.69.5).

We construct such a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ explicitly. Namely, for every $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$, we define $\mathbf{i}((T, (i_1, i_2, \ldots, i_n)))$ as follows: Construct a sequence $(T_0, T_1, \ldots, T_n)$ of column-strict tableaux recursively: We set $T_0 = T$. For every $k \in \{1, 2, \ldots, n\}$, if T_{k-1} is already defined, we let T_k be the column-strict tableau obtained by applying RS-insertion to the tableau T_{k-1} and the letter i_k. (This RS-insertion also returns a corner cell, but we do not care about it.) Thus, a sequence $(T_0, T_1, \ldots, T_n)$ is defined. We now set $S = T_n$, and let λ^+ be the shape of S. It is easy to see that λ^+/λ is a horizontal n-strip[605]. Thus, $(\lambda^+, S) \in \mathbf{B}$. Now,

[605] *Proof.* Notice that $i_1 \leq i_2 \leq \cdots \leq i_n$ (since $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$). The tableau S has been obtained from T by applying RS-insertion n times, using the letters $i_1, i_2, \ldots, i_n$ in this order. Each time that we have applied RS-insertion, the shape of our tableau has grown by a new cell. According to Lemma 13.69.1(a), each of these cells (except for the first one) lies in a column further right than the previous one (because the letters $i_1, i_2, \ldots, i_n$ that we inserted satisfy $i_1 \leq i_2 \leq \cdots \leq i_n$). Therefore, no two of these cells lie in the same column. Since these cells are precisely the cells of λ^+/λ (because λ^+ is the shape of S, while λ is the shape of T), this means that no two cells of λ^+/λ lie in the same column. In other words, λ^+/λ is a

set $\mathbf{i}((T,(i_1,i_2,\ldots,i_n))) = (\lambda^+, S)$. We have therefore defined a map $\mathbf{i} : \mathbf{A} \to \mathbf{B}$. It remains to prove that this map $\mathbf{i}$ is a bijection and satisfies (13.69.5).

Proving that the map $\mathbf{i}$ satisfies (13.69.5) is easy[606]. It remains to show that $\mathbf{i}$ is a bijection. We will achieve this by constructing an inverse map.

Indeed, let us define a map $\mathbf{r} : \mathbf{B} \to \mathbf{A}$. For every $(\lambda^+, S) \in \mathbf{B}$, we define $\mathbf{r}((\lambda^+, S))$ as follows: We know that λ^+/λ is a horizontal n-strip (since $(\lambda^+, S) \in \mathbf{B}$). We can thus uniquely label the n cells of λ^+/λ by $c_1, c_2, \ldots, c_n$ from right to left. Consider these cells $c_1, c_2, \ldots, c_n$. Construct a sequence $(S_0, S_1, \ldots, S_n)$ of column-strict tableaux and a sequence $(j_1, j_2, \ldots, j_n)$ of positive integers recursively: We set $S_0 = S$. For every $k \in \{1, 2, \ldots, n\}$, if S_{k-1} is already defined, we apply reverse bumping to the tableau S_{k-1} and its corner cell c_k. We denote the resulting tableau by S_k, and the resulting letter by j_k. [607] Thus, two sequences $(S_0, S_1, \ldots, S_n)$ and $(j_1, j_2, \ldots, j_n)$ are defined. We now set $T = S_n$ and $(i_1, i_2, \ldots, i_n) = (j_n, j_{n-1}, \ldots, j_1)$. So the tableau T is obtained from S by successively applying reverse bumping using

horizontal strip. Since λ^+/λ has precisely n cells (because we have applied RS-insertion exactly n times, gaining precisely one cell every time), this yields that λ^+/λ is a horizontal n-strip, qed.

[606] *Proof.* Assume that some $(T,(i_1,i_2,\ldots,i_n)) \in \mathbf{A}$ and $\left(\lambda^+, S\right) \in \mathbf{B}$ satisfy $\mathbf{i}((T,(i_1,i_2,\ldots,i_n))) = \left(\lambda^+, S\right)$. We need to show that (13.69.5) holds.

According to the definition of $\mathbf{i}((T,(i_1,i_2,\ldots,i_n)))$, the tableau S is obtained by successively applying RS-insertion to the tableau T using the letters $i_1, i_2, \ldots, i_n$. But whenever a tableau V results from applying RS-insertion to a column-strict tableau U and a letter j, the multiset of entries of V is obtained from the multiset of entries of U by tossing in the letter j. Thus, the multiset of entries of S is obtained from the multiset of entries of T by tossing in the n letters $i_1, i_2, \ldots, i_n$ (because S is obtained by successively applying RS-insertion to the tableau T using the letters $i_1, i_2, \ldots, i_n$). Hence, $\mathbf{x}^{\operatorname{cont}(S)} = \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n}$. Thus, (13.69.5) is proven.

[607] In order to verify that this definition makes sense, we need to check that c_k is a corner cell of S_{k-1} for each $k \in \{1, 2, \ldots, n\}$. Let us sketch a proof of this fact.

In fact, we shall show a stronger claim:

> *Claim CC:* For each $k \in \{1, 2, \ldots, n\}$, the shape of the tableau S_{k-1} is obtained from λ^+ by removing the corner cells $c_1, c_2, \ldots, c_{k-1}$, and the cell c_k is a corner cell of S_{k-1}.

Proof. We use induction over k.

Induction base: The shape of the tableau S_0 is λ^+ (since $S_0 = S$ has shape λ^+), which is clearly the shape obtained from λ^+ by removing the corner cells $c_1, c_2, \ldots, c_0$. Moreover, the cell c_1 is the rightmost cell of λ^+/λ (since we labelled the cells of λ^+/λ by $c_1, c_2, \ldots, c_n$ from right to left), and thus has no cells of λ^+ to its right in its row; but it also has no cells of λ^+ below it in its column (since any such cell would have to belong to λ^+/λ, but λ^+/λ is a horizontal strip and therefore cannot have two cells in the same column). Thus, c_1 is a corner cell of $S = S_0$. Therefore, Claim CC is proven for $k = 1$. This completes the induction base.

Induction step: Fix some $K \in \{1, 2, \ldots, n-1\}$. Assume that Claim CC is proven for $k = K$. We need to show that Claim CC holds for $k = K + 1$.

We know that Claim CC is proven for $k = K$. In other words, the shape of the tableau S_{K-1} is obtained from λ^+ by removing the corner cells $c_1, c_2, \ldots, c_{K-1}$, and the cell c_K is a corner cell of S_{K-1}. Now, the shape of the tableau S_K is obtained from the shape of S_{K-1} by removing the corner cell c_K (because S_K is obtained by applying reverse bumping to the tableau S_{K-1} and its corner cell c_K), and thus is obtained from λ^+ by removing the corner cells $c_1, c_2, \ldots, c_K$ (since the shape of the tableau S_{K-1} is obtained from λ^+ by removing the corner cells $c_1, c_2, \ldots, c_{K-1}$). Hence, $c_1, c_2, \ldots, c_K$ are not cells of S_K, but c_{K+1} is a cell of S_K (since c_{K+1} is a cell of λ^+/λ, therefore is a cell of λ^+, and is not among the K cells $c_1, c_2, \ldots, c_K$ that were removed). We shall now show that the cell c_{K+1} is a corner cell of S_K.

Indeed, assume the contrary. Thus, c_{K+1} is a cell of S_K, but not a corner cell. Hence, there exists a cell d of S_K that is either the bottom neighbor or the right neighbor of c_{K+1} (that is, it either lies in the same column as c_{K+1} but one step further down, or lies in the same row as c_{K+1} but one step further right). Consider this cell d.

Recall that the cells of λ^+/λ have been labelled $c_1, c_2, \ldots, c_n$ from right to left. Therefore, the cell c_{K+1} belongs to λ^+/λ. Hence, c_{K+1} is not a cell of λ. Therefore, d is not a cell of λ either (since d is either the bottom neighbor or the right neighbor of c_{K+1}). But d is a cell of S_K, thus a cell of λ^+ (since the shape of the tableau S_K is obtained from λ^+ by removing some cells). Hence, the cell d must also belong to λ^+/λ (since d is not a cell of λ). If d was the bottom neighbor of c_{K+1}, we would thus conclude that c_{K+1} and d are two cells of λ^+/λ that lie in the same column; but this is impossible (since λ^+/λ is a horizontal strip and thus cannot have two cells in the same column). Hence, d cannot be the bottom neighbor of c_{K+1}. Thus, d must be the right neighbor of c_{K+1} (since d is either the bottom neighbor or the right neighbor of c_{K+1}). Thus, d lies further right than c_{K+1}. But all cells of λ^+/λ that lie further right than c_{K+1} are $c_1, c_2, \ldots, c_K$ (since the cells of λ^+/λ have been labelled $c_1, c_2, \ldots, c_n$ from right to left). Hence, any cell of λ^+/λ that lies further right than c_{K+1} must be one of $c_1, c_2, \ldots, c_K$. Thus, d must be one of $c_1, c_2, \ldots, c_K$ (since d is a cell of λ^+/λ that lies further right than c_{K+1}). Hence, d cannot be a cell of S_K (since $c_1, c_2, \ldots, c_K$ are not cells of S_K). This contradicts the fact that d is a cell of S_K.

This contradiction shows that our assumption was wrong. Hence, the cell c_{K+1} is a corner cell of S_K.

Thus we have shown that the shape of the tableau S_K is obtained from λ^+ by removing the corner cells $c_1, c_2, \ldots, c_K$, and the cell c_{K+1} is a corner cell of S_K. This proves Claim CC for $k = K + 1$. Thus, the induction step is finished. Claim CC is thus proven. We hence conclude that our definition makes sense.

the corner cells $c_1, c_2, \ldots, c_n$ (in this order), and $j_1, j_2, \ldots, j_n$ are the letters that are obtained from the reverse-bumping procedure. Since reverse bumping is the inverse map to RS-insertion, this yields that we can obtain S back from T by successively applying RS-insertion using the letters $j_n, j_{n-1}, \ldots, j_1$ (that is, the letters $i_1, i_2, \ldots, i_n$), and that these successive RS-insertion steps recover the corner cells $c_n, c_{n-1}, \ldots, c_1$ in this order. Now, it is easy to see that the tableau T has shape λ (because in passing from S to T, we lost the corner cells $c_n, c_{n-1}, \ldots, c_1$, which are exactly the cells of λ^+/λ) and the letters $i_1, i_2, \ldots, i_n$ satisfy $i_1 \leq i_2 \leq \cdots \leq i_n$ [608]. Hence, $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$. We set $\mathbf{r}((\lambda^+, S)) = (T, (i_1, i_2, \ldots, i_n))$. The map $\mathbf{r} : \mathbf{B} \to \mathbf{A}$ is thus defined. It is now easy to prove that the maps $\mathbf{i}$ and $\mathbf{r}$ are mutually inverse (since RS-insertion and reverse bumping are inverse maps), and thus $\mathbf{i}$ is a bijection. Thus, there exists a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ which has the property (13.69.5). This completes our proof of (2.7.1). □

The proof of (2.7.2) is almost entirely analogous. We give it for the sake of completeness (but most of it is copypasted material from the proof above).

Alternative proof of (2.7.2). Let λ be a partition, and let $n \in \mathbb{N}$. The definition of s_λ yields

$$s_\lambda = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(T)}.$$

The definition of h_n yields

$$e_n = \sum_{i_1 < i_2 < \cdots < i_n} x_{i_1} x_{i_2} \cdots x_{i_n} = \sum_{i_n > i_{n-1} > \cdots > i_1} x_{i_n} x_{i_{n-1}} \cdots x_{i_1} = \sum_{i_1 > i_2 > \cdots > i_n} x_{i_1} x_{i_2} \cdots x_{i_n} \tag{13.69.6}$$

(here, we substituted $(i_1, i_2, \ldots, i_n)$ for $(i_n, i_{n-1}, \ldots, i_1)$ in the sum). Multiplying these two identities, we obtain

$$\begin{aligned} s_\lambda e_n &= \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(T)} \sum_{i_1 > i_2 > \cdots > i_n} x_{i_1} x_{i_2} \cdots x_{i_n} \\ &= \sum_{(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}} \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n}, \qquad (13.69.7) \end{aligned}$$

where $\mathbf{A}$ is the set of all pairs $(T, (i_1, i_2, \ldots, i_n))$ of a column-strict tableau T of shape λ and an n-tuple $(i_1, i_2, \ldots, i_n)$ of positive integers satisfying $i_1 > i_2 > \cdots > i_n$. Consider this set $\mathbf{A}$.

On the other hand, every partition λ^+ satisfies

$$\begin{aligned} s_{\lambda^+} &= \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(T)} && \left(\text{by the definition of } s_{\lambda^+}\right) \\ &= \sum_{\substack{S \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(S)} && \left(\text{here, we renamed the summation index } T \text{ as } S\right). \qquad (13.69.8) \end{aligned}$$

[608] *Proof.* Assume the contrary. Then, we don't have $i_1 \leq i_2 \leq \cdots \leq i_n$. In other words, we don't have $j_n \leq j_{n-1} \leq \cdots \leq j_1$ (since $(i_1, i_2, \ldots, i_n) = (j_n, j_{n-1}, \ldots, j_1)$). Hence, there exists a $k \in \{2, 3, \ldots, n\}$ such that $j_k > j_{k-1}$. Consider this k. Recall that the tableau S_k and the letter j_k were obtained by applying reverse bumping to the tableau S_{k-1} and its corner cell c_k, while the tableau S_{k-1} and the letter j_{k-1} were obtained by applying reverse bumping to the tableau S_{k-2} and its corner cell c_{k-1}. Since reverse bumping is the inverse map to RS-insertion, this entails that conversely, the tableau S_{k-1} and its corner cell c_k are obtained by applying RS-insertion to the tableau S_k and the letter j_k, and the tableau S_{k-2} and its corner cell c_{k-1} are obtained by applying RS-insertion to the tableau S_{k-1} and the letter j_{k-1}. Hence, Lemma 13.69.1(b) (applied to S_k, j_k, j_{k-1}, S_{k-1}, c_k, S_{k-2} and c_{k-1} instead of P, j, j', P', c, P'' and c') yields that the cell c_{k-1} is in the same column as c_k or in a column further left. But this contradicts the fact that c_{k-1} lies in a column further right than c_k (since the cells of λ^+/λ were labelled by $c_1, c_2, \ldots, c_n$ **from right to left**, and lie in different columns). This contradiction completes our proof.

Hence,

$$\sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{vertical } n\text{-strip}}} \underbrace{s_{\lambda^+}}_{\substack{= \sum_{\substack{S \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(S)} \\ \text{(by (13.69.8))}}} = \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{vertical } n\text{-strip}}} \sum_{\substack{S \text{ is a column-strict} \\ \text{tableau of shape } \lambda^+}} \mathbf{x}^{\operatorname{cont}(S)}$$

$$= \sum_{(\lambda^+, S) \in \mathbf{B}} \mathbf{x}^{\operatorname{cont}(S)}, \qquad (13.69.9)$$

where $\mathbf{B}$ is the set of all pairs (λ^+, S) of a partition λ^+ and a column-strict tableau S of shape λ^+ such that λ^+/λ is a vertical n-strip. Consider this set $\mathbf{B}$.

We shall now prove that there exists a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ which has the property that

$$\mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n} = \mathbf{x}^{\operatorname{cont}(S)} \qquad (13.69.10)$$

whenever some $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$ and $(\lambda^+, S) \in \mathbf{B}$ satisfy $\mathbf{i}((T, (i_1, i_2, \ldots, i_n))) = (\lambda^+, S)$. Once this will be proven, it will immediately follow that $\sum_{(T,(i_1,i_2,\ldots,i_n)) \in \mathbf{A}} \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n} = \sum_{(\lambda^+,S)\in\mathbf{B}} \mathbf{x}^{\operatorname{cont}(S)}$, and therefore (13.69.7) will become

$$s_\lambda e_n = \sum_{(T,(i_1,i_2,\ldots,i_n))\in\mathbf{A}} \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n} = \sum_{(\lambda^+,S)\in\mathbf{B}} \mathbf{x}^{\operatorname{cont}(S)} = \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+} \qquad \text{(by (13.69.9))},$$

and thus (2.7.2) will be proven. Hence, in order to complete the proof of (2.7.2), it is enough to prove that there exists a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ which has the property (13.69.10).

We construct such a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ explicitly. Namely, for every $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$, we define $\mathbf{i}((T, (i_1, i_2, \ldots, i_n)))$ as follows: Construct a sequence $(T_0, T_1, \ldots, T_n)$ of column-strict tableaux recursively: We set $T_0 = T$. For every $k \in \{1, 2, \ldots, n\}$, if T_{k-1} is already defined, we let T_k be the column-strict tableau obtained by applying RS-insertion to the tableau T_{k-1} and the letter i_k. (This RS-insertion also returns a corner cell, but we do not care about it.) Thus, a sequence $(T_0, T_1, \ldots, T_n)$ is defined. We now set $S = T_n$, and let λ^+ be the shape of S. It is easy to see that λ^+/λ is a vertical n-strip[609]. Thus, $(\lambda^+, S) \in \mathbf{B}$. Now, set $\mathbf{i}((T, (i_1, i_2, \ldots, i_n))) = (\lambda^+, S)$. We have therefore defined a map $\mathbf{i} : \mathbf{A} \to \mathbf{B}$. It remains to prove that this map $\mathbf{i}$ is a bijection and satisfies (13.69.10).

Proving that the map $\mathbf{i}$ satisfies (13.69.10) is easy[610]. It remains to show that $\mathbf{i}$ is a bijection. We will achieve this by constructing an inverse map.

Indeed, let us define a map $\mathbf{r} : \mathbf{B} \to \mathbf{A}$. For every $(\lambda^+, S) \in \mathbf{B}$, we define $\mathbf{r}((\lambda^+, S))$ as follows: We know that λ^+/λ is a vertical n-strip (since $(\lambda^+, S) \in \mathbf{B}$). We can thus uniquely label the n cells of λ^+/λ by $c_1, c_2, \ldots, c_n$ from bottom to top. Consider these cells $c_1, c_2, \ldots, c_n$. Construct a sequence $(S_0, S_1, \ldots, S_n)$ of column-strict tableaux and a sequence $(j_1, j_2, \ldots, j_n)$ of positive integers recursively: We set $S_0 = S$. For every $k \in \{1, 2, \ldots, n\}$, if S_{k-1} is already defined, we apply reverse bumping to the tableau S_{k-1} and its corner cell c_k. We denote the resulting tableau by S_k, and the resulting letter by j_k. [611] Thus,

[609] *Proof.* Notice that $i_1 > i_2 > \cdots > i_n$ (since $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$). The tableau S has been obtained from T by applying RS-insertion n times, using the letters $i_1, i_2, \ldots, i_n$ in this order. Each time that we have applied RS-insertion, the shape of our tableau has grown by a new cell. According to Lemma 13.69.1(b), each of these cells (except for the first one) lies in a row further down than the previous one (because the letters $i_1, i_2, \ldots, i_n$ that we inserted satisfy $i_1 > i_2 > \cdots > i_n$). Therefore, no two of these cells lie in the same row. Since these cells are precisely the cells of λ^+/λ (because λ^+ is the shape of S, while λ is the shape of T), this means that no two cells of λ^+/λ lie in the same row. In other words, λ^+/λ is a vertical strip. Since λ^+/λ has precisely n cells (because we have applied RS-insertion exactly n times, gaining precisely one cell every time), this yields that λ^+/λ is a vertical n-strip, qed.

[610] *Proof.* Assume that some $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$ and $(\lambda^+, S) \in \mathbf{B}$ satisfy $\mathbf{i}((T, (i_1, i_2, \ldots, i_n))) = (\lambda^+, S)$. We need to show that (13.69.10) holds.

According to the definition of $\mathbf{i}((T, (i_1, i_2, \ldots, i_n)))$, the tableau S is obtained by successively applying RS-insertion to the tableau T using the letters $i_1, i_2, \ldots, i_n$. But whenever a tableau V results from applying RS-insertion to a column-strict tableau U and a letter j, the multiset of entries of V is obtained from the multiset of entries of U by tossing in the letter j. Thus, the multiset of entries of S is obtained from the multiset of entries of T by tossing in the n letters $i_1, i_2, \ldots, i_n$ (because S is obtained by successively applying RS-insertion to the tableau T using the letters $i_1, i_2, \ldots, i_n$). Hence, $\mathbf{x}^{\operatorname{cont}(S)} = \mathbf{x}^{\operatorname{cont}(T)} x_{i_1} x_{i_2} \cdots x_{i_n}$. Thus, (13.69.10) is proven.

[611] One again has to check that this is well-defined. The proof is very similar to the analogous argument in our proof of (2.7.1), and is left to the reader.

two sequences $(S_0, S_1, \ldots, S_n)$ and $(j_1, j_2, \ldots, j_n)$ are defined. We now set $T = S_n$ and $(i_1, i_2, \ldots, i_n) = (j_n, j_{n-1}, \ldots, j_1)$. So the tableau T is obtained from S by successively applying reverse bumping using the corner cells $c_1, c_2, \ldots, c_n$ (in this order), and $j_1, j_2, \ldots, j_n$ are the letters that are obtained from the reverse-bumping procedure. Since reverse bumping is the inverse map to RS-insertion, this yields that we can obtain S back from T by successively applying RS-insertion using the letters $j_n, j_{n-1}, \ldots, j_1$ (that is, the letters $i_1, i_2, \ldots, i_n$), and that these successive RS-insertion steps recover the corner cells $c_n, c_{n-1}, \ldots, c_1$ in this order. Now, it is easy to see that the tableau T has shape λ (because in passing from S to T, we lost the corner cells $c_n, c_{n-1}, \ldots, c_1$, which are exactly the cells of λ^+/λ) and the letters $i_1, i_2, \ldots, i_n$ satisfy $i_1 > i_2 > \cdots > i_n$ [612]. Hence, $(T, (i_1, i_2, \ldots, i_n)) \in \mathbf{A}$. We set $\mathbf{r}((\lambda^+, S)) = (T, (i_1, i_2, \ldots, i_n))$. The map $\mathbf{r} : \mathbf{B} \to \mathbf{A}$ is thus defined. It is now easy to prove that the maps $\mathbf{i}$ and $\mathbf{r}$ are mutually inverse (since RS-insertion and reverse bumping are inverse maps), and thus $\mathbf{i}$ is a bijection. Thus, there exists a bijection $\mathbf{i} : \mathbf{A} \to \mathbf{B}$ which has the property (13.69.10). This completes our proof of (2.7.2). □

Now, both (2.7.1) and (2.7.2) are proven. Hence, Theorem 2.7.1 is proven again.

13.70. **Solution to Exercise 2.7.8.** *Solution to Exercise 2.7.8.* Before we start solving any specific part of this exercise, let us state some general properties of determinants (and prove some of them):

- Every $m \in \mathbb{N}$ and every matrix $(\alpha_{i,j})_{i,j=1,2,\ldots,m} \in A^{m\times m}$ satisfy

$$\det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m}\right) = \sum_{\sigma\in\mathfrak{S}_m} (-1)^\sigma \prod_{i=1}^m \alpha_{i,\sigma(i)}. \tag{13.70.1}$$

(This is simply the explicit formula for the determinant of a matrix as a sum over permutations.)

- If a positive integer m and a matrix $(\alpha_{i,j})_{i,j=1,2,\ldots,m} \in A^{m\times m}$ are such that every $j \in \{1, 2, ..., m-1\}$ satisfies $\alpha_{m,j} = 0$, then

$$\det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m}\right) = \alpha_{m,m} \cdot \det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m-1}\right). \tag{13.70.2}$$

[613]

- Every positive integer m and every matrix $(\alpha_{i,j})_{i,j=1,2,\ldots,m} \in A^{m\times m}$ satisfy

$$\det\left((\alpha_{i,j}\alpha_{m,m} - \alpha_{i,m}\alpha_{m,j})_{i,j=1,2,\ldots,m-1}\right) = \alpha_{m,m}^{m-2} \cdot \det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m}\right) \tag{13.70.3}$$

if $\alpha_{m,m}$ is an invertible element of A.

Proof of (13.70.3)*:* Let m be a positive integer. Let $(\alpha_{i,j})_{i,j=1,2,\ldots,m} \in A^{m\times m}$ be a matrix such that $\alpha_{m,m}$ is an invertible element of A.

[612] *Proof.* Assume the contrary. Then, we don't have $i_1 > i_2 > \cdots > i_n$. In other words, we don't have $j_n > j_{n-1} > \cdots > j_1$ (since $(i_1, i_2, \ldots, i_n) = (j_n, j_{n-1}, \ldots, j_1)$). Hence, there exists a $k \in \{2, 3, \ldots, n\}$ such that $j_k \leq j_{k-1}$. Consider this k. Recall that the tableau S_k and the letter j_k were obtained by applying reverse bumping to the tableau S_{k-1} and its corner cell c_k, while the tableau S_{k-1} and the letter j_{k-1} were obtained by applying reverse bumping to the tableau S_{k-2} and its corner cell c_{k-1}. Since reverse bumping is the inverse map to RS-insertion, this entails that conversely, the tableau S_{k-1} and its corner cell c_k are obtained by applying RS-insertion to the tableau S_k and the letter j_k, and the tableau S_{k-2} and its corner cell c_{k-1} are obtained by applying RS-insertion to the tableau S_{k-1} and the letter j_{k-1}. Hence, Lemma 13.69.1(a) (applied to S_k, j_k, j_{k-1}, S_{k-1}, c_k, S_{k-2} and c_{k-1} instead of P, j, j', P', c, P'' and c') yields that the cell c_{k-1} is in the same row as c_k or in a row further up. But this contradicts the fact that c_{k-1} lies in a row further down than c_k (since the cells of λ^+/λ were labelled by $c_1, c_2, \ldots, c_n$ **from bottom to top**, and lie in different rows). This contradiction completes our proof.

[613] In fact, the condition that every $j \in \{1, 2, ..., m-1\}$ satisfies $\alpha_{m,j} = 0$ means that all entries of the m-th row of the $m \times m$-matrix $(\alpha_{i,j})_{i,j=1,2,\ldots,m}$ are zeroes apart from (possibly) the last entry. Hence, applying Laplace expansion to the determinant $\det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m}\right)$ of this matrix yields a sum of products, all of which are zero apart from

$$\alpha_{m,m} \cdot \underbrace{\left(\text{the } (m,m)\text{-th cofactor of the matrix } (\alpha_{i,j})_{i,j=1,2,\ldots,m}\right)}_{=(-1)^{m+m}\cdot\det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m-1}\right)=\det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m-1}\right)} = \alpha_{m,m} \cdot \det\left((\alpha_{i,j})_{i,j=1,2,\ldots,m-1}\right).$$

For every $(i,j) \in \{1,2,...,m\}^2$, define an element $\beta_{i,j}$ of A by

$$\beta_{i,j} = \begin{cases} \alpha_{m,m}, & \text{if } i = j; \\ -\alpha_{m,j}, & \text{if } i = m \text{ and } j \neq m \end{cases} . \tag{13.70.4}$$

Then, the matrix $(\beta_{i,j})_{i,j=1,2,...,m}$ is lower-triangular. Since the determinant of a lower-triangular matrix equals the product of its diagonal entries, we thus have

$$\det\left((\beta_{i,j})_{i,j=1,2,...,m}\right) = \prod_{i=1}^{m} \underbrace{\beta_{i,i}}_{\substack{=\alpha_{m,m} \\ \text{(this is} \\ \text{easily seen)}}} = \prod_{i=1}^{m} \alpha_{m,m} = \alpha_{m,m}^m . \tag{13.70.5}$$

But since the determinant of a product of two square matrices equals the product of their determinants, we have

$$\begin{aligned} \det\left((\alpha_{i,j})_{i,j=1,2,...,m} \cdot (\beta_{i,j})_{i,j=1,2,...,m}\right) &= \det\left((\alpha_{i,j})_{i,j=1,2,...,m}\right) \cdot \underbrace{\det\left((\beta_{i,j})_{i,j=1,2,...,m}\right)}_{\substack{=\alpha_{m,m}^m \\ \text{(by (13.70.5))}}} \\ &= \det\left((\alpha_{i,j})_{i,j=1,2,...,m}\right) \cdot \alpha_{m,m}^m . \end{aligned}$$

Since $(\alpha_{i,j})_{i,j=1,2,...,m} \cdot (\beta_{i,j})_{i,j=1,2,...,m} = \left(\sum_{k=1}^m \alpha_{i,k}\beta_{k,j}\right)_{i,j=1,2,...,m}$, this rewrites as

$$\det\left(\left(\sum_{k=1}^m \alpha_{i,k}\beta_{k,j}\right)_{i,j=1,2,...,m}\right) = \det\left((\alpha_{i,j})_{i,j=1,2,...,m}\right) \cdot \alpha_{m,m}^m . \tag{13.70.6}$$

Now, for every $(i,j) \in \{1,2,...,m\}^2$, define an element $\gamma_{i,j}$ of A by

$$\gamma_{i,j} = \sum_{k=1}^m \alpha_{i,k}\beta_{k,j} . \tag{13.70.7}$$

Then,

$$\det\left((\gamma_{i,j})_{i,j=1,2,...,m}\right) = \det\left(\left(\sum_{k=1}^m \alpha_{i,k}\beta_{k,j}\right)_{i,j=1,2,...,m}\right) = \det\left((\alpha_{i,j})_{i,j=1,2,...,m}\right) \cdot \alpha_{m,m}^m \tag{13.70.8}$$

(by (13.70.6)).

However, for every (i,j), we can simplify the expression for $\gamma_{i,j}$ given by (13.70.7) by plugging in the definition of $\beta_{k,j}$ (which guarantees that no more than two of the terms of the sum will be nonzero). We obtain

$$\gamma_{i,j} = \begin{cases} \alpha_{i,j}\alpha_{m,m} - \alpha_{i,m}\alpha_{m,j}, & \text{if } i \neq m \text{ and } j \neq m; \\ 0, & \text{if } i = m \text{ and } j \neq m; \\ \alpha_{i,m}\alpha_{m,m}, & \text{if } j = m \end{cases} . \tag{13.70.9}$$

In particular, this shows that every $j \in \{1,2,...,m-1\}$ satisfies $\gamma_{m,j} = 0$. Hence, (13.70.2) (applied to $\gamma_{i,j}$ instead of $\alpha_{i,j}$) yields

$$\begin{aligned} \det\left((\gamma_{i,j})_{i,j=1,2,...,m}\right) &= \underbrace{\gamma_{m,m}}_{\substack{=\alpha_{m,m}\alpha_{m,m} \\ \text{(by (13.70.9), since } m=m)}} \cdot \det\left(\left(\underbrace{\gamma_{i,j}}_{\substack{=\alpha_{i,j}\alpha_{m,m}-\alpha_{i,m}\alpha_{m,j} \\ \text{(by (13.70.9), since } i\neq m \text{ and } j\neq m)}}\right)_{i,j=1,2,...,m-1}\right) \\ &= \alpha_{m,m}\alpha_{m,m} \cdot \det\left((\alpha_{i,j}\alpha_{m,m} - \alpha_{i,m}\alpha_{m,j})_{i,j=1,2,...,m-1}\right) \\ &= \alpha_{m,m}^2 \cdot \det\left((\alpha_{i,j}\alpha_{m,m} - \alpha_{i,m}\alpha_{m,j})_{i,j=1,2,...,m-1}\right) . \end{aligned}$$

Compared with (13.70.8), this yields

$$\alpha_{m,m}^2 \cdot \det\left(\left(\alpha_{i,j}\alpha_{m,m} - \alpha_{i,m}\alpha_{m,j}\right)_{i,j=1,2,\ldots,m-1}\right) = \det\left(\left(\alpha_{i,j}\right)_{i,j=1,2,\ldots,m}\right) \cdot \alpha_{m,m}^m.$$

We can divide both sides of this equality by $\alpha_{m,m}^2$ (since $\alpha_{m,m}$ is invertible in A), and thus obtain

$$\det\left(\left(\alpha_{i,j}\alpha_{m,m} - \alpha_{i,m}\alpha_{m,j}\right)_{i,j=1,2,\ldots,m-1}\right) = \alpha_{m,m}^{m-2} \cdot \det\left(\left(\alpha_{i,j}\right)_{i,j=1,2,\ldots,m}\right).$$

This proves (13.70.3).

[*Remark:* The equality (13.70.3) holds even without requiring that $\alpha_{m,m}$ be invertible, if we have $m \geq 2$ (of course, if m is not ≥ 2, then the $\alpha_{m,m}^{m-2}$ on the right hand side of (13.70.3) does not make sense unless $\alpha_{m,m}$ is invertible). There are several ways to see why this is so. One of these ways proceeds as follows: First of all, one should notice that our above proof of (13.70.3) works without requiring that $\alpha_{m,m}$ be invertible, as long as $\alpha_{m,m}$ is a non-zero-divisor[614] in A and we have $m \geq 2$. However, for any fixed $m \geq 2$, the equality (13.70.3) is a polynomial identity in the elements $\alpha_{i,j}$ of A; thus, it suffices to prove it when $\alpha_{i,j}$ are distinct indeterminates $X_{i,j}$ in the polynomial ring $\mathbb{Z}\left[X_{i,j} \mid (i,j) \in \{1,2,...,m\}^2\right]$. But in this case, $\alpha_{m,m}$ is clearly a non-zero-divisor, and so our above proof applies. (An alternative approach would be to replace $\alpha_{m,m}$ by $X + \alpha_{m,m}$ in the polynomial ring $A[X]$; again, $X + \alpha_{m,m}$ is a non-zero-divisor even if $\alpha_{m,m}$ is not.)]

Now, rather than solve parts (a) and (b) of the exercise separately, we are going to prove a result from which both of these parts will easily follow:

Proposition 13.70.1. *Let A be a commutative ring. Let $n \in \mathbb{N}$. For every $i \in \{1,2,...,n\}$, let a_i, b_i, c_i and d_i be four elements of A. Assume that $a_i d_j - b_i c_j$ is an invertible element of A for every $i \in \{1,2,...,n\}$ and $j \in \{1,2,...,n\}$. Then,*

$$\det\left(\left(\frac{1}{a_i d_j - b_i c_j}\right)_{i,j=1,2,\ldots,n}\right) = \frac{\prod_{1\leq j<i\leq n}\left(\left(a_i b_j - a_j b_i\right)\left(c_j d_i - c_i d_j\right)\right)}{\prod_{(i,j)\in\{1,2,\ldots,n\}^2}\left(a_i d_j - b_i c_j\right)}$$

Proof of Proposition 13.70.1. We prove this by induction over n. The base case ($n = 0$) is obvious, as it claims an equality between the determinant of a 0×0-matrix (defined to be 1) and the ratio of two empty products (thus $\frac{1}{1} = 1$). For the induction step, we fix some positive integer m, and we set out to prove the equality

$$\det\left(\left(\frac{1}{a_i d_j - b_i c_j}\right)_{i,j=1,2,\ldots,m}\right) = \frac{\prod_{1\leq j<i\leq m}\left(\left(a_i b_j - a_j b_i\right)\left(c_j d_i - c_i d_j\right)\right)}{\prod_{(i,j)\in\{1,2,\ldots,m\}^2}\left(a_i d_j - b_i c_j\right)}, \tag{13.70.10}$$

assuming that we already know

$$\det\left(\left(\frac{1}{a_i d_j - b_i c_j}\right)_{i,j=1,2,\ldots,m-1}\right) = \frac{\prod_{1\leq j<i\leq m-1}\left(\left(a_i b_j - a_j b_i\right)\left(c_j d_i - c_i d_j\right)\right)}{\prod_{(i,j)\in\{1,2,\ldots,m-1\}^2}\left(a_i d_j - b_i c_j\right)} \tag{13.70.11}$$

to be true.

Now, we know that $\frac{1}{a_m d_m - b_m c_m}$ is an invertible element of A (because it is the inverse of $a_m d_m - b_m c_m$). Thus, (13.70.3) (applied to $\alpha_{i,j} = \frac{1}{a_i d_j - b_i c_j}$) yields

$$\begin{aligned}&\det\left(\left(\frac{1}{a_i d_j - b_i c_j} \cdot \frac{1}{a_m d_m - b_m c_m} - \frac{1}{a_i d_m - b_i c_m} \cdot \frac{1}{a_m d_j - b_m c_j}\right)_{i,j=1,2,\ldots,m-1}\right)\\ &= \left(\frac{1}{a_m d_m - b_m c_m}\right)^{m-2} \cdot \det\left(\left(\frac{1}{a_i d_j - b_i c_j}\right)_{i,j=1,2,\ldots,m}\right).\end{aligned}$$

[614] A *non-zero-divisor* in a commutative ring B means an element $b \in B$ such that every element $c \in B$ satisfying $bc = 0$ must satisfy $c = 0$.

Solving this for $\det\left(\left(\frac{1}{a_id_j-b_ic_j}\right)_{i,j=1,2,...,m}\right)$, we obtain

$$\det\left(\left(\frac{1}{a_id_j-b_ic_j}\right)_{i,j=1,2,...,m}\right)$$
(13.70.12)
$$=(a_md_m-b_mc_m)^{m-2}\cdot\det\left(\left(\frac{1}{a_id_j-b_ic_j}\cdot\frac{1}{a_md_m-b_mc_m}-\frac{1}{a_id_m-b_ic_m}\cdot\frac{1}{a_md_j-b_mc_j}\right)_{i,j=1,2,...,m-1}\right).$$

But straightforward computations show that every $(i,j)\in\{1,2,...,m\}^2$ satisfy

$$\frac{1}{a_id_j-b_ic_j}\cdot\frac{1}{a_md_m-b_mc_m}-\frac{1}{a_id_m-b_ic_m}\cdot\frac{1}{a_md_j-b_mc_j}$$
$$=\frac{c_jd_m-c_md_j}{(a_md_m-b_mc_m)(a_md_j-b_mc_j)}\cdot\frac{a_mb_i-a_ib_m}{a_id_m-b_ic_m}\cdot\frac{1}{a_id_j-b_ic_j}.$$

Hence, the matrix

$$\left(\frac{1}{a_id_j-b_ic_j}\cdot\frac{1}{a_md_m-b_mc_m}-\frac{1}{a_id_m-b_ic_m}\cdot\frac{1}{a_md_j-b_mc_j}\right)_{i,j=1,2,...,m-1}$$

can be rewritten as

$$\left(\frac{c_jd_m-c_md_j}{(a_md_m-b_mc_m)(a_md_j-b_mc_j)}\cdot\frac{a_mb_i-a_ib_m}{a_id_m-b_ic_m}\cdot\frac{1}{a_id_j-b_ic_j}\right)_{i,j=1,2,...,m-1}.$$

This means that this matrix can be obtained from the matrix $\left(\frac{1}{a_id_j-b_ic_j}\right)_{i,j=1,2,...,m-1}$ by multiplying every row with $\frac{a_mb_i-a_ib_m}{a_id_m-b_ic_m}$, where i is the index of this row, and then multiplying every column with $\frac{c_jd_m-c_md_j}{(a_md_m-b_mc_m)(a_md_j-b_mc_j)}$, where j is the index of the column. As a consequence, the determinant of this matrix is

$$\left(\prod_{j=1}^{m-1}\frac{c_jd_m-c_md_j}{(a_md_m-b_mc_m)(a_md_j-b_mc_j)}\right)\cdot\left(\prod_{i=1}^{m-1}\frac{a_mb_i-a_ib_m}{a_id_m-b_ic_m}\right)\cdot\det\left(\left(\frac{1}{a_id_j-b_ic_j}\right)_{i,j=1,2,...,m-1}\right)$$

(because when a row of a matrix is multiplied by a scalar, the determinant of the matrix gets multiplied by the same scalar, and the same rule holds for columns). Hence, we have shown that

$$\det\left(\left(\frac{1}{a_id_j-b_ic_j}\cdot\frac{1}{a_md_m-b_mc_m}-\frac{1}{a_id_m-b_ic_m}\cdot\frac{1}{a_md_j-b_mc_j}\right)_{i,j=1,2,...,m-1}\right)$$
$$=\left(\prod_{j=1}^{m-1}\frac{c_jd_m-c_md_j}{(a_md_m-b_mc_m)(a_md_j-b_mc_j)}\right)\cdot\left(\prod_{i=1}^{m-1}\frac{a_mb_i-a_ib_m}{a_id_m-b_ic_m}\right)\cdot\underbrace{\det\left(\left(\frac{1}{a_id_j-b_ic_j}\right)_{i,j=1,2,...,m-1}\right)}_{\substack{=\frac{\prod_{1\leq j<i\leq m-1}((a_ib_j-a_jb_i)(c_jd_i-c_id_j))}{\prod_{(i,j)\in\{1,2,...,m-1\}^2}(a_id_j-b_ic_j)}\\ \text{(by (13.70.11))}}}$$
$$=\left(\prod_{j=1}^{m-1}\frac{c_jd_m-c_md_j}{(a_md_m-b_mc_m)(a_md_j-b_mc_j)}\right)\cdot\left(\prod_{i=1}^{m-1}\frac{a_mb_i-a_ib_m}{a_id_m-b_ic_m}\right)\cdot\frac{\prod_{1\leq j<i\leq m-1}((a_ib_j-a_jb_i)(c_jd_i-c_id_j))}{\prod_{(i,j)\in\{1,2,...,m-1\}^2}(a_id_j-b_ic_j)}.$$

We can now plug this into (13.70.12) and make straightforward simplifications (splitting apart and pulling together products), and obtain (13.70.10). Thus, the induction step is complete, and Proposition 13.70.1 is proven.

Now, let us solve the exercise.

(a) *First solution of Exercise 2.7.8(a):* Exercise 2.7.8(a) follows from Proposition 13.70.1 (applied to a_i, 1, b_i and 1 instead of a_i, b_i, c_i and d_i).

Second solution of Exercise 2.7.8(a) (sketched): The statement of Exercise 2.7.8(a) is an identity between two rational functions in the variables $a_1, a_2, ..., a_n, b_1, b_2, ..., b_n$, and is easily seen to be equivalent to a polynomial identity in these variables (by multiplying both sides through with the common denominator $\prod_{(i,j)\in\{1,2,...,n\}^2} (a_i - b_j)$). It is well-known that such identities need only be checked on complex numbers to ensure that they hold for any elements of any ring. So we only need to prove the statement of Exercise 2.7.8(a) in the case when $A = \mathbb{C}$. But the statement is well-known in this case (see, e.g., [69, Lemma 5.15.3 (Lemma 4.48 in the arXiv version)] and various other sources for the proof).

(b) *First solution of Exercise 2.7.8(b):* Exercise 2.7.8(b) follows from Proposition 13.70.1 (applied to 1, a_i, b_i and 1 instead of a_i, b_i, c_i and d_i).

Second solution of Exercise 2.7.8(b): Just as in the Second solution of Exercise 2.7.8(a), we can see that it is enough to solve Exercise 2.7.8(b) in the case when $A = \mathbb{C}$. But in this case, the statement of this exercise is well-known, and proven, e.g., in [69, Corollary 5.15.4 (Corollary 4.49 in the arXiv version)] and [44, Cauchy's lemma, p. 18].

Remark: One could also derive the statement of Exercise 2.7.8(b) from Exercise 2.7.8(a) by applying the latter to $1/a_i$ instead of a_i, after first WLOG assuming that the a_i are invertible (but one needs to justify this WLOG assumption).

(c) *Alternative proof of Theorem 2.5.1.* We are going to show that, for every $n \in \mathbb{N}$, we have

$$\prod_{i,j=1}^{n} (1 - x_i y_j)^{-1} = \sum_{\lambda\in\mathrm{Par}} s_\lambda (x_1, x_2, ..., x_n) s_\lambda (y_1, y_2, ..., y_n) \tag{13.70.13}$$

in the ring $\mathbf{k}[[x_1, x_2, ..., x_n, y_1, y_2, ..., y_n]]$. Once this is proven, Theorem 2.5.1 will easily follow.[615]

So let $n \in \mathbb{N}$. For every $i \in \{1, 2, ..., n\}$ and $j \in \{1, 2, ..., n\}$, the element $1 - x_i y_j$ of the ring $\mathbf{k}[[x_1, x_2, ..., x_n, y_1, y_2, ..., y_n]]$ is invertible. Hence, Exercise 2.7.8(b) (applied to $A = \mathbf{k}[[x_1, x_2, ..., x_n, y_1, y_2, ..., y_n]]$, $a_i = x_i$ and $b_j = y_j$) yields

$$\det\left(\left(\frac{1}{1 - x_i y_j}\right)_{i,j=1,2,...,n}\right) = \frac{\prod_{1\le j<i\le n} ((x_i - x_j)(y_i - y_j))}{\prod_{(i,j)\in\{1,2,...,n\}^2} (1 - x_i y_j)} = \frac{\prod_{1\le i<j\le n} ((x_i - x_j)(y_i - y_j))}{\prod_{(i,j)\in\{1,2,...,n\}^2} (1 - x_i y_j)}$$

$$= \left(\prod_{1\le i<j\le n} (x_i - x_j)\right) \cdot \left(\prod_{1\le i<j\le n} (y_i - y_j)\right) \cdot \prod_{i,j=1}^{n} \frac{1}{1 - x_i y_j} \tag{13.70.14}$$

in the ring $\mathbf{k}[[x_1, x_2, ..., x_n, y_1, y_2, ..., y_n]]$.

We will use the notations of Definition 2.6.2 and Proposition 2.6.4 (but we do not require $\mathbf{k}$ to be $\mathbb{Z}$ or a field of characteristic not equal to 2 as was done in Proposition 2.6.4). We have $a_\rho = \prod_{1\le i<j\le n} (x_i - x_j)$ (as

[615] *Proof.* Assume that (13.70.13) is proven for all $n \in \mathbb{N}$. We need to show that

$$\prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1} = \sum_{\lambda\in\mathrm{Par}} s_\lambda (\mathbf{x}) s_\lambda (\mathbf{y})$$

in the ring $\mathbf{k}[[\mathbf{x}, \mathbf{y}]] = \mathbf{k}[[x_1, x_2, x_3, ..., y_1, y_2, y_3, ...]]$. In order to do so, it is clearly enough to prove that for any two weak compositions α and β, the coefficient of $\mathbf{x}^\alpha \mathbf{y}^\beta$ in $\prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1}$ equals the coefficient of $\mathbf{x}^\alpha \mathbf{y}^\beta$ in $\sum_{\lambda\in\mathrm{Par}} s_\lambda (\mathbf{x}) s_\lambda (\mathbf{y})$. So fix two weak compositions α and β. Write α and β as $\alpha = (\alpha_1, \alpha_2, \alpha_3, ...)$ and $\beta = (\beta_1, \beta_2, \beta_3, ...)$. Choose some $n \in \mathbb{N}$ such that every integer $m > n$ satisfies $\alpha_m = \beta_m = 0$. (Such an m clearly exists, since α and β are finitely supported.) Then, the coefficient of $\mathbf{x}^\alpha \mathbf{y}^\beta$ in $\prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1}$ equals the coefficient of $x_1^{\alpha_1} x_2^{\alpha_2} ... x_n^{\alpha_n} y_1^{\beta_1} y_2^{\beta_2} ... y_n^{\beta_n}$ in $\prod_{i,j=1}^{n} (1 - x_i y_j)^{-1}$, whereas the coefficient of $\mathbf{x}^\alpha \mathbf{y}^\beta$ in $\sum_{\lambda\in\mathrm{Par}} s_\lambda (\mathbf{x}) s_\lambda (\mathbf{y})$ equals the coefficient of $x_1^{\alpha_1} x_2^{\alpha_2} ... x_n^{\alpha_n} y_1^{\beta_1} y_2^{\beta_2} ... y_n^{\beta_n}$ in $\sum_{\lambda\in\mathrm{Par}} s_\lambda (x_1, x_2, ..., x_n) s_\lambda (y_1, y_2, ..., y_n)$. Since the coefficients of $x_1^{\alpha_1} x_2^{\alpha_2} ... x_n^{\alpha_n} y_1^{\beta_1} y_2^{\beta_2} ... y_n^{\beta_n}$ in $\prod_{i,j=1}^{n} (1 - x_i y_j)^{-1}$ and in $\sum_{\lambda\in\mathrm{Par}} s_\lambda (x_1, x_2, ..., x_n) s_\lambda (y_1, y_2, ..., y_n)$ are equal (because of (13.70.13)), this shows that the coefficients of $\mathbf{x}^\alpha \mathbf{y}^\beta$ in $\prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1}$ and in $\sum_{\lambda\in\mathrm{Par}} s_\lambda (\mathbf{x}) s_\lambda (\mathbf{y})$ are equal; but this is exactly what we need to prove. Thus, Theorem 2.5.1 follows if (13.70.13) is proven.

proven in the proof of Proposition 2.6.4). Thus, $a_\rho(x_1,x_2,...,x_n) = \prod_{1\leq i<j\leq n}(x_i-x_j)$ and $a_\rho(y_1,y_2,...,y_n) = \prod_{1\leq i<j\leq n}(y_i-y_j)$. Thus, (13.70.14) becomes

$$\begin{aligned}
&\det\left(\left(\frac{1}{1-x_iy_j}\right)_{i,j=1,2,...,n}\right)\\
&=\underbrace{\left(\prod_{1\leq i<j\leq n}(x_i-x_j)\right)}_{=a_\rho(x_1,x_2,...,x_n)}\cdot\underbrace{\left(\prod_{1\leq i<j\leq n}(y_i-y_j)\right)}_{=a_\rho(y_1,y_2,...,y_n)}\cdot\prod_{i,j=1}^{n}\underbrace{\frac{1}{1-x_iy_j}}_{=(1-x_iy_j)^{-1}}\\
&=a_\rho(x_1,x_2,...,x_n)\cdot a_\rho(y_1,y_2,...,y_n)\cdot\prod_{i,j=1}^{n}(1-x_iy_j)^{-1}. \qquad (13.70.15)
\end{aligned}$$

On the other hand, (13.70.1) (applied to $m=n$ and $\alpha_{i,j}=\frac{1}{1-x_iy_j}$) yields

$$\begin{aligned}
\det\left(\left(\frac{1}{1-x_iy_j}\right)_{i,j=1,2,...,n}\right) &= \sum_{\sigma\in S_n}(-1)^\sigma\prod_{i=1}^{n}\underbrace{\frac{1}{1-x_iy_{\sigma(i)}}}_{\substack{=\sum_{k\in\mathbb{N}}\left(x_iy_{\sigma(i)}\right)^k\\ \text{(by the formula for the geometric series)}}}\\
&=\sum_{\sigma\in S_n}(-1)^\sigma\underbrace{\prod_{i=1}^{n}\sum_{k\in\mathbb{N}}\left(x_iy_{\sigma(i)}\right)^k}_{\substack{=\sum_{(k_1,k_2,...,k_n)\in\mathbb{N}^n}\left(x_1y_{\sigma(1)}\right)^{k_1}\left(x_2y_{\sigma(2)}\right)^{k_2}...\left(x_ny_{\sigma(n)}\right)^{k_n}\\ \text{(by the product rule)}}}\\
&=\sum_{\sigma\in S_n}(-1)^\sigma\sum_{(k_1,k_2,...,k_n)\in\mathbb{N}^n}\underbrace{\left(x_1y_{\sigma(1)}\right)^{k_1}\left(x_2y_{\sigma(2)}\right)^{k_2}...\left(x_ny_{\sigma(n)}\right)^{k_n}}_{\substack{=\left(x_1^{k_1}y_{\sigma(1)}^{k_1}\right)\left(x_2^{k_2}y_{\sigma(2)}^{k_2}\right)...\left(x_n^{k_n}y_{\sigma(n)}^{k_n}\right)\\ =\left(x_1^{k_1}x_2^{k_2}...x_n^{k_n}\right)\left(y_{\sigma(1)}^{k_1}y_{\sigma(2)}^{k_2}...y_{\sigma(n)}^{k_n}\right)}}\\
&=\sum_{\sigma\in S_n}(-1)^\sigma\sum_{(k_1,k_2,...,k_n)\in\mathbb{N}^n}\left(x_1^{k_1}x_2^{k_2}...x_n^{k_n}\right)\left(y_{\sigma(1)}^{k_1}y_{\sigma(2)}^{k_2}...y_{\sigma(n)}^{k_n}\right)\\
&=\sum_{(k_1,k_2,...,k_n)\in\mathbb{N}^n}x_1^{k_1}x_2^{k_2}...x_n^{k_n}\sum_{\sigma\in S_n}(-1)^\sigma y_{\sigma(1)}^{k_1}y_{\sigma(2)}^{k_2}...y_{\sigma(n)}^{k_n}. \qquad (13.70.16)
\end{aligned}$$

But every $(k_1,k_2,...,k_n)\in\mathbb{N}^n$ satisfies

$$\begin{aligned}
\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,...,n}\right) &= \sum_{\sigma\in S_n}(-1)^\sigma\underbrace{\prod_{i=1}^{n}y_{\sigma(i)}^{k_i}}_{=y_{\sigma(1)}^{k_1}y_{\sigma(2)}^{k_2}...y_{\sigma(n)}^{k_n}} \qquad \left(\text{by (13.70.1), applied to } m=n \text{ and } \alpha_{i,j}=y_j^{k_i}\right)\\
&=\sum_{\sigma\in S_n}(-1)^\sigma y_{\sigma(1)}^{k_1}y_{\sigma(2)}^{k_2}...y_{\sigma(n)}^{k_n}. \qquad (13.70.17)
\end{aligned}$$

Hence, (13.70.16) becomes

$$\begin{aligned}
\det\left(\left(\frac{1}{1-x_iy_j}\right)_{i,j=1,2,\ldots,n}\right) &= \sum_{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \underbrace{\sum_{\sigma\in S_n}(-1)^\sigma y_{\sigma(1)}^{k_1}y_{\sigma(2)}^{k_2}\ldots y_{\sigma(n)}^{k_n}}_{\substack{=\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)\\ \text{(by (13.70.17))}}} \\
&= \sum_{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ \text{the integers } k_1,\ k_2,\ \ldots,\ k_n\\ \text{are distinct}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right). \qquad (13.70.18)
\end{aligned}$$

(Here, we have removed from our sum all addends in which the integers k_1, k_2, ..., k_n are not distinct. This did not change the value of the sum, because all these addends are zero[616].)

On the other hand, every $(k_1, k_2, ..., k_n) \in \mathbb{N}^n$ satisfies

$$\begin{aligned}
\det\left(\left(x_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) &= \sum_{\sigma\in S_n}(-1)^\sigma \underbrace{\prod_{i=1}^n x_{\sigma(i)}^{k_i}}_{=x_{\sigma(1)}^{k_1}x_{\sigma(2)}^{k_2}\ldots x_{\sigma(n)}^{k_n}} \qquad \left(\text{by (13.70.1), applied to } m=n \text{ and } \alpha_{i,j}=x_j^{k_i}\right) \\
&= \sum_{\sigma\in S_n}(-1)^\sigma x_{\sigma(1)}^{k_1}x_{\sigma(2)}^{k_2}\ldots x_{\sigma(n)}^{k_n}.
\end{aligned}$$

[616] In fact, if $(k_1, k_2, ..., k_n) \in \mathbb{N}^n$ is such that the integers k_1, k_2, ..., k_n are **not** distinct, then the matrix $\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}$ has two equal rows, which causes its determinant $\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)$ to be 0, and thus the addend corresponding to this $(k_1, k_2, ..., k_n) \in \mathbb{N}^n$ is

$$x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \underbrace{\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)}_{=0} = 0.$$

Thus,

$$\begin{aligned}
&\sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_1>k_2>\ldots>k_n}} \underbrace{\det\left(\left(x_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)}_{=\sum_{\sigma\in S_n}(-1)^\sigma x_{\sigma(1)}^{k_1}x_{\sigma(2)}^{k_2}\ldots x_{\sigma(n)}^{k_n}} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_1>k_2>\ldots>k_n}} \sum_{\sigma\in S_n} (-1)^\sigma x_{\sigma(1)}^{k_1}x_{\sigma(2)}^{k_2}\ldots x_{\sigma(n)}^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \sum_{\sigma\in S_n} (-1)^\sigma \underbrace{\sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_1>k_2>\ldots>k_n}} x_{\sigma(1)}^{k_1}x_{\sigma(2)}^{k_2}\ldots x_{\sigma(n)}^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)}_{\substack{=\sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} x_{\sigma(1)}^{k_{\sigma(1)}}x_{\sigma(2)}^{k_{\sigma(2)}}\ldots x_{\sigma(n)}^{k_{\sigma(n)}} \det\left(\left(y_j^{k_{\sigma(i)}}\right)_{i,j=1,2,\ldots,n}\right)\\ \text{(here, we substituted } \left(k_{\sigma(1)},k_{\sigma(2)},\ldots,k_{\sigma(n)}\right) \text{ for } (k_1,k_2,\ldots,k_n) \text{ in the sum}\\ \text{(this is allowed, since } \sigma \text{ is a permutation))}}} \\
&= \sum_{\sigma\in S_n} (-1)^\sigma \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} \underbrace{x_{\sigma(1)}^{k_{\sigma(1)}}x_{\sigma(2)}^{k_{\sigma(2)}}\ldots x_{\sigma(n)}^{k_{\sigma(n)}}}_{\substack{=x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n}\\ \text{(since } \sigma \text{ is a permutation)}}} \underbrace{\det\left(\left(y_j^{k_{\sigma(i)}}\right)_{i,j=1,2,\ldots,n}\right)}_{\substack{=(-1)^\sigma \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)\\ \text{(since permuting the rows of a matrix}\\ \text{multiplies its determinant by the sign}\\ \text{of the permutation)}}} \\
&= \sum_{\sigma\in S_n} (-1)^\sigma \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} (-1)^\sigma \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \sum_{\sigma\in S_n} \underbrace{(-1)^\sigma (-1)^\sigma}_{=((-1)^\sigma)^2=1} \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \underbrace{\sum_{\sigma\in S_n} \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}}}_{=\sum_{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n} \sum_{\substack{\sigma\in S_n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \sum_{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n} \sum_{\substack{\sigma\in S_n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ \text{the integers } k_1,\ k_2,\ \ldots,\ k_n\\ \text{are distinct}}} \underbrace{\sum_{\substack{\sigma\in S_n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)}_{\substack{=x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)\\ \text{(because there exists exactly one } \sigma\in S_n \text{ such that } k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}\\ \text{(since the integers } k_1,\ k_2,\ \ldots,\ k_n \text{ are distinct, and thus}\\ \text{there is exactly one permutation which arranges these integers}\\ \text{in decreasing order))}}} \\
&\qquad + \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ \text{the integers } k_1,\ k_2,\ \ldots,\ k_n\\ \text{are not distinct}}} \sum_{\substack{\sigma\in S_n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n} \underbrace{\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)}_{\substack{=0\\ \text{(because the matrix } \left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\\ \text{has two equal rows (since the integers}\\ k_1,\ k_2,\ \ldots,\ k_n \text{ are not distinct,}\\ \text{i. e., there are two equal among them))}}}
\end{aligned}$$

$$= \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ \text{the integers } k_1,\ k_2,\ \ldots,\ k_n\\ \text{are distinct}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n}\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)$$
$$+ \underbrace{\sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ \text{the integers } k_1,\ k_2,\ \ldots,\ k_n\\ \text{are not distinct}}} \sum_{\substack{\sigma\in S_n;\\ k_{\sigma(1)}>k_{\sigma(2)}>\ldots>k_{\sigma(n)}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n}0}_{=0}$$
$$= \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ \text{the integers } k_1,\ k_2,\ \ldots,\ k_n\\ \text{are distinct}}} x_1^{k_1}x_2^{k_2}\ldots x_n^{k_n}\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right).$$

Compared with (13.70.18), this yields

$$\det\left(\left(\frac{1}{1-x_iy_j}\right)_{i,j=1,2,\ldots,n}\right)$$
$$= \sum_{\substack{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n;\\ k_1>k_2>\ldots>k_n}} \det\left(\left(x_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)\det\left(\left(y_j^{k_i}\right)_{i,j=1,2,\ldots,n}\right)$$
$$= \underbrace{\sum_{\substack{(\lambda_1,\lambda_2,\ldots,\lambda_n)\in\mathbb{N}^n;\\ \lambda_1\geq\lambda_2\geq\ldots\geq\lambda_n}}}_{=\sum_{\substack{\lambda=(\lambda_1,\lambda_2,\ldots,\lambda_n)\in\mathbb{N}^n\\ \text{is a partition with at most } n \text{ parts}}}} \det\left(\left(x_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)\det\left(\left(y_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)$$
$$\left(\begin{array}{c}\text{here, we substituted } (\lambda_1+n-1,\lambda_2+n-2,\ldots,\lambda_n+n-n) \text{ for } (k_1,k_2,\ldots,k_n)\\ \text{in the sum (since the map}\\ \{(\lambda_1,\lambda_2,\ldots,\lambda_n)\in\mathbb{N}^n \mid \lambda_1\geq\lambda_2\geq\ldots\geq\lambda_n\}\to\{(k_1,k_2,\ldots,k_n)\in\mathbb{N}^n \mid k_1>k_2>\ldots>k_n\},\\ (\lambda_1,\lambda_2,\ldots,\lambda_n)\mapsto(\lambda_1+n-1,\lambda_2+n-2,\ldots,\lambda_n+n-n)\\ \text{is a bijection)}\end{array}\right)$$

(13.70.19)
$$= \sum_{\substack{\lambda=(\lambda_1,\lambda_2,\ldots,\lambda_n)\in\mathbb{N}^n\\ \text{is a partition with at most } n \text{ parts}}} \det\left(\left(x_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)\det\left(\left(y_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right).$$

But whenever $\lambda=(\lambda_1,\lambda_2,\ldots,\lambda_n)$ is a partition with at most n parts, we have

$$\underbrace{\lambda}_{=(\lambda_1,\lambda_2,\ldots,\lambda_n)} + \underbrace{\rho}_{=(n-1,n-2,\ldots,0)} = (\lambda_1,\lambda_2,\ldots,\lambda_n)+(n-1,n-2,\ldots,0)$$
$$= (\lambda_1+n-1,\lambda_2+n-2,\ldots,\lambda_n+n-n)$$

and thus

$$\begin{aligned}
a_{\lambda+\rho} &= a_{(\lambda_1+n-1,\lambda_2+n-2,\ldots,\lambda_n+n-n)} = \det\left(\underbrace{\left(x_i^{\lambda_j+n-j}\right)_{i,j=1,2,\ldots,n}}_{=\left(\left(x_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)^T}\right) \\
&\qquad \left(\text{by the definition of } a_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}\right) \\
&= \det\left(\left(\left(x_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)^T\right) = \det\left(\left(x_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right) \\
&\qquad (\text{since the determinant of a matrix is preserved under transposition}) .
\end{aligned}$$

Hence, we get the two equalities $a_{\lambda+\rho}(x_1,x_2,\ldots,x_n) = \det\left(\left(x_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)$ and $a_{\lambda+\rho}(y_1,y_2,\ldots,y_n) = \det\left(\left(y_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)$ for any partition $\lambda = (\lambda_1,\lambda_2,\ldots,\lambda_n)$ with at most n parts. Thus, (13.70.19) becomes

$$\begin{aligned}
&\det\left(\left(\frac{1}{1-x_iy_j}\right)_{i,j=1,2,\ldots,n}\right) \\
&= \sum_{\substack{\lambda=(\lambda_1,\lambda_2,\ldots,\lambda_n)\in\mathbb{N}^n \\ \text{is a partition with at most } n \text{ parts}}} \underbrace{\det\left(\left(x_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)}_{=a_{\lambda+\rho}(x_1,x_2,\ldots,x_n)} \underbrace{\det\left(\left(y_j^{\lambda_i+n-i}\right)_{i,j=1,2,\ldots,n}\right)}_{=a_{\lambda+\rho}(y_1,y_2,\ldots,y_n)} \\
&= \sum_{\substack{\lambda=(\lambda_1,\lambda_2,\ldots,\lambda_n)\in\mathbb{N}^n \\ \text{is a partition with at most } n \text{ parts}}} a_{\lambda+\rho}(x_1,x_2,\ldots,x_n)\, a_{\lambda+\rho}(y_1,y_2,\ldots,y_n) \\
&= \sum_{\lambda \text{ is a partition with at most } n \text{ parts}} a_{\lambda+\rho}(x_1,x_2,\ldots,x_n)\, a_{\lambda+\rho}(y_1,y_2,\ldots,y_n) .
\end{aligned}$$

Compared to (13.70.14), this yields

$$\begin{aligned}
&\sum_{\lambda \text{ is a partition with at most } n \text{ parts}} a_{\lambda+\rho}(x_1,x_2,\ldots,x_n)\, a_{\lambda+\rho}(y_1,y_2,\ldots,y_n) \\
&= \underbrace{\left(\prod_{1\leq i<j\leq n} (x_i - x_j)\right)}_{=a_\rho(x_1,x_2,\ldots,x_n)} \cdot \underbrace{\left(\prod_{1\leq i<j\leq n} (y_i - y_j)\right)}_{=a_\rho(y_1,y_2,\ldots,y_n)} \cdot \prod_{i,j=1}^{n} \underbrace{\frac{1}{1-x_iy_j}}_{=(1-x_iy_j)^{-1}} \\
&= a_\rho(x_1,x_2,\ldots,x_n) \cdot a_\rho(y_1,y_2,\ldots,y_n) \cdot \prod_{i,j=1}^{n} (1-x_iy_j)^{-1} . \qquad (13.70.20)
\end{aligned}$$

Now, Corollary 2.6.7 says that $s_\lambda(x_1,x_2,\ldots,x_n) = \frac{a_{\lambda+\rho}}{a_\rho}$ for every partition λ with at most n parts. Thus, $s_\lambda(x_1,x_2,\ldots,x_n) = \frac{a_{\lambda+\rho}(x_1,x_2,\ldots,x_n)}{a_\rho(x_1,x_2,\ldots,x_n)}$ and $s_\lambda(y_1,y_2,\ldots,y_n) = \frac{a_{\lambda+\rho}(y_1,y_2,\ldots,y_n)}{a_\rho(y_1,y_2,\ldots,y_n)}$ for every partition λ

with at most n parts. Hence,

$$\begin{aligned}
&\sum_{\lambda \text{ is a partition with at most } n \text{ parts}} \underbrace{s_\lambda\left(x_1,x_2,...,x_n\right)}_{=\dfrac{a_{\lambda+\rho}\left(x_1,x_2,...,x_n\right)}{a_\rho\left(x_1,x_2,...,x_n\right)}} \underbrace{s_\lambda\left(y_1,y_2,...,y_n\right)}_{=\dfrac{a_{\lambda+\rho}\left(y_1,y_2,...,y_n\right)}{a_\rho\left(y_1,y_2,...,y_n\right)}} \\
&= \sum_{\lambda \text{ is a partition with at most } n \text{ parts}} \frac{a_{\lambda+\rho}\left(x_1,x_2,...,x_n\right)}{a_\rho\left(x_1,x_2,...,x_n\right)} \cdot \frac{a_{\lambda+\rho}\left(y_1,y_2,...,y_n\right)}{a_\rho\left(y_1,y_2,...,y_n\right)} \\
&= \frac{1}{a_\rho\left(x_1,x_2,...,x_n\right)\cdot a_\rho\left(y_1,y_2,...,y_n\right)} \underbrace{\sum_{\lambda \text{ is a partition with at most } n \text{ parts}} a_{\lambda+\rho}\left(x_1,x_2,...,x_n\right) a_{\lambda+\rho}\left(y_1,y_2,...,y_n\right)}_{\substack{=a_\rho(x_1,x_2,...,x_n)\cdot a_\rho(y_1,y_2,...,y_n)\cdot \prod_{i,j=1}^{n}(1-x_iy_j)^{-1} \\ \text{(by (13.70.20))}}} \\
&= \frac{1}{a_\rho\left(x_1,x_2,...,x_n\right)\cdot a_\rho\left(y_1,y_2,...,y_n\right)} \cdot a_\rho\left(x_1,x_2,...,x_n\right)\cdot a_\rho\left(y_1,y_2,...,y_n\right)\cdot \prod_{i,j=1}^{n}\left(1-x_iy_j\right)^{-1}
\end{aligned}$$

(13.70.21)
$$= \prod_{i,j=1}^{n}\left(1-x_iy_j\right)^{-1}.$$

We are almost done. Let us now notice that every partition λ with more than n parts satisfies

$$s_\lambda\left(x_1,x_2,...,x_n\right) = 0 \qquad (13.70.22)$$

(according to Exercise 2.3.8(b)). Thus, in the sum $\sum_{\lambda\in\operatorname{Par}} s_\lambda\left(x_1,x_2,...,x_n\right) s_\lambda\left(y_1,y_2,...,y_n\right)$, all addends corresponding to partitions λ having more than n parts are 0. We can therefore remove these addends from the sum. Hence,

$$\begin{aligned}
&\sum_{\lambda\in\operatorname{Par}} s_\lambda\left(x_1,x_2,...,x_n\right) s_\lambda\left(y_1,y_2,...,y_n\right) \\
&= \sum_{\lambda \text{ is a partition with at most } n \text{ parts}} s_\lambda\left(x_1,x_2,...,x_n\right) s_\lambda\left(y_1,y_2,...,y_n\right) \\
&= \prod_{i,j=1}^{n}\left(1-x_iy_j\right)^{-1} \qquad \text{(by (13.70.21))}.
\end{aligned}$$

Thus, we have proven that (13.70.13) holds for every $n\in\mathbb{N}$. As we explained above, this yields that Theorem 2.5.1 is true.

Remark: In our above solution, we solved Exercise 2.7.8(b) first, and then used it to prove Theorem 2.5.1. It is also possible (more or less by treading the above proof backwards) to conversely derive the statement of Exercise 2.7.8(b) from Theorem 2.5.1 instead (though Exercise 2.7.8(b) is usually considered a more elementary fact than Theorem 2.5.1).

13.71. **Solution to Exercise 2.7.9.** *Solution to Exercise 2.7.9.* Let us first check that we have

$$h_u h_v = \sum_{i=0}^{v} s_{(u+i,v-i)} \qquad (13.71.1)$$

for any two nonnegative integers u and v satisfying $u\geq v$.

Proof of (13.71.1)*:* Let u and v be nonnegative integers satisfying $u\geq v$. We WLOG assume that $u>0$ (otherwise, $u=0$, and $u\geq v$ forces $v=0$, so that (13.71.1) can be checked immediately). We have $h_u = s_{(u)}$

and thus

$$h_u h_v = s_{(u)} h_v = \sum_{\substack{\lambda^+ \ : \ \lambda^+/(u) \text{ is a} \\ \text{horizontal } v\text{-strip}}} s_{\lambda^+} \tag{13.71.2}$$

(by (2.7.1), applied to $n = v$ and $\lambda = (u)$).

Now, fix a partition λ^+ such that $\lambda^+ / (u)$ is a horizontal v-strip. Then, the skew diagram $\lambda^+ / (u)$ has at most one cell in column 1 (since $\lambda^+ / (u)$ is a horizontal v-strip and thus contains no two cells in the same column). Hence, the partition λ^+ has at most 2 rows (because otherwise, the skew diagram $\lambda^+ / (u)$ would contain at least two cells in column 1, which would contradict the fact that the skew diagram $\lambda^+ / (u)$ has at most one cell in column 1). Thus, the partition λ^+ has the form (p, q) for two nonnegative integers p and q satisfying $p \geq q$. Consider these two integers p and q. Since $\lambda^+ / (u)$ is a horizontal v-strip, we have $|\lambda^+ / (u)| = v$ and thus $v = |\lambda^+ / (u)| = \left| \underbrace{\lambda^+}_{=(p,q)} \right| - \underbrace{|(u)|}_{=u} = \underbrace{|(p,q)|}_{=p+q} - u = p + q - u$. Moreover, $\lambda^+ / (u)$ is a horizontal v-strip, so that $(u) \subseteq \lambda^+ = (p, q)$. Thus, $u \leq p$. Hence, there exists an $i \in \mathbb{N}$ such that $p = u + i$. Consider this i. Now, $v = \underbrace{p}_{=u+i} + q - u = u + i + q - u = q + i$, so that $q = v - i$ and thus $v - i = q \geq 0$, so that $i \leq v$ and thus $i \in \{0, 1, ..., v\}$ (since $i \in \mathbb{N}$). Hence, $\lambda^+ = \left(\underbrace{p}_{=u+i}, \underbrace{q}_{=v-i} \right) = (u + i, v - i)$. We have thus shown that the partition λ^+ has the form $\lambda^+ = (u + i, v - i)$ for some $i \in \{0, 1, ..., v\}$.

Now forget that we fixed λ^+. We thus have proven that every partition λ^+ such that $\lambda^+ / (u)$ is a horizontal v-strip has the form $\lambda^+ = (u + i, v - i)$ for some $i \in \{0, 1, ..., v\}$. Conversely, it is clear that for every $i \in \{0, 1, ..., v\}$, the weak composition $(u + i, v - i)$ is a partition λ^+ such that $\lambda^+ / (u)$ is a horizontal v-strip. Combining the previous two sentences, we conclude that the partitions λ^+ such that $\lambda^+ / (u)$ is a horizontal v-strip are precisely the weak compositions of the form $(u + i, v - i)$ for $i \in \{0, 1, ..., v\}$. Therefore, $\sum_{\substack{\lambda^+ \ : \ \lambda^+/(u) \text{ is a} \\ \text{horizontal } v\text{-strip}}} s_{\lambda^+} = \sum_{i \in \{0,1,...,v\}} s_{(u+i,v-i)} = \sum_{i=0}^{v} s_{(u+i,v-i)}$. Now, (13.71.2) becomes

$$h_u h_v = \sum_{\substack{\lambda^+ \ : \ \lambda^+/(u) \text{ is a} \\ \text{horizontal } v\text{-strip}}} s_{\lambda^+} = \sum_{i=0}^{v} s_{(u+i,v-i)}.$$

This proves (13.71.1).

Now, fix two integers a and b satisfying $a \geq b \geq 0$. We need to prove that $s_{(a,b)} = h_a h_b - h_{a+1} h_{b-1}$.

If $b = 0$, then proving $s_{(a,b)} = h_a h_b - h_{a+1} h_{b-1}$ is very easy[617]. Hence, for the rest of the proof of $s_{(a,b)} = h_a h_b - h_{a+1} h_{b-1}$, we assume WLOG that we don't have $b = 0$. Thus, $b \geq 1$, so that $b - 1 \geq 0$. Clearly, $a \geq b$ shows that $a + 1 \geq b + 1 \geq b - 1$, so that we can apply (13.71.1) to $u = a + 1$ and $v = b - 1$.

[617] In fact, assume that $b = 0$. Then,

$$s_{(a,b)} = s_{(a,0)} = s_{(a)} = h_a$$

and

$$h_a \underbrace{h_b}_{=h_0=1} - h_{a+1} \underbrace{h_{b-1}}_{=h_{-1}=0} = h_a 1 - h_{a+1} 0 = h_a.$$

Hence, $s_{(a,b)} = h_a = h_a h_b - h_{a+1} h_{b-1}$, qed.

Now,

$$\begin{aligned}
&\underbrace{h_a h_b}_{\substack{=\sum_{i=0}^{b} s_{(a+i,b-i)} \\ \text{(by (13.71.1), applied} \\ \text{to } u=a \text{ and } v=b)}} - \underbrace{h_{a+1} h_{b-1}}_{\substack{=\sum_{i=0}^{b-1} s_{(a+1+i,b-1-i)} \\ \text{(by (13.71.1), applied} \\ \text{to } u=a+1 \text{ and } v=b-1)}} \\
&= \underbrace{\sum_{i=0}^{b} s_{(a+i,b-i)}}_{=s_{(a+0,b-0)}+\sum_{i=1}^{b} s_{(a+i,b-i)}} - \sum_{i=0}^{b-1} \underbrace{s_{(a+1+i,b-1-i)}}_{=s_{(a+(i+1),b-(i+1))}} = s_{(a+0,b-0)} + \sum_{i=1}^{b} s_{(a+i,b-i)} - \sum_{i=0}^{b-1} s_{(a+(i+1),b-(i+1))} \\
&= s_{(a+0,b-0)} + \sum_{i=1}^{b} s_{(a+i,b-i)} - \sum_{i=1}^{b} s_{(a+i,b-i)} \\
&\qquad \text{(here, we have substituted } i \text{ for } i+1 \text{ in the second sum)} \\
&= s_{(a+0,b-0)} = s_{(a,b)}.
\end{aligned}$$

We thus have proven $s_{(a,b)} = h_a h_b - h_{a+1} h_{b-1}$. The exercise is solved.

13.72. **Solution to Exercise 2.7.10.** *Solution to Exercise 2.7.10.* (a) We shall prove the statement of Exercise 2.7.10(a) by induction over the length $\ell(\mu)$ of μ.

The *induction base* (i.e., the case $\ell(\mu) = 0$) is trivial. For the *induction step*, we fix a positive integer L and assume (as the induction hypothesis) that Exercise 2.7.10(a) has been solved for all μ satisfying $\ell(\mu) = L - 1$. We now have to solve Exercise 2.7.10(a) for every partition μ satisfying $\ell(\mu) = L$.

So let μ be a partition satisfying $\ell(\mu) = L$. Write μ in the form $(\mu_1, \mu_2, \ldots, \mu_L)$. Let $\overline{\mu}$ be the partition $(\mu_1, \mu_2, \ldots, \mu_{L-1})$ (this is well-defined since L is positive). Then, $\ell(\overline{\mu}) = L - 1$, and hence (by the induction hypothesis) we can apply Exercise 2.7.10(a) to $\overline{\mu}$ instead of μ. As a result, we obtain $h_{\overline{\mu}} = \sum_\lambda K_{\lambda,\overline{\mu}} s_\lambda$, where the sum ranges over all partitions λ.

But the definition of h_μ yields $h_\mu = h_{\mu_1} h_{\mu_2} \ldots h_{\mu_L}$; similarly, $h_{\overline{\mu}} = h_{\mu_1} h_{\mu_2} \ldots h_{\mu_{L-1}}$. Hence,

$$\begin{aligned}
h_\mu &= h_{\mu_1} h_{\mu_2} \ldots h_{\mu_L} = \underbrace{h_{\mu_1} h_{\mu_2} \ldots h_{\mu_{L-1}}}_{=h_{\overline{\mu}}=\sum_\lambda K_{\lambda,\overline{\mu}} s_\lambda} h_{\mu_L} = \left(\sum_\lambda K_{\lambda,\overline{\mu}} s_\lambda \right) h_{\mu_L} \\
&= \sum_\lambda K_{\lambda,\overline{\mu}} \underbrace{s_\lambda h_{\mu_L}}_{\substack{= \sum_{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a horizontal } \mu_L\text{-strip}} s_{\lambda^+} \\ \text{(by (2.7.1), applied to } n=\mu_L)}} = \sum_\lambda K_{\lambda,\overline{\mu}} \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a horizontal} \\ \mu_L\text{-strip}}} s_{\lambda^+} \\
&= \underbrace{\sum_\lambda \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a horizontal} \\ \mu_L\text{-strip}}}}_{=\sum_{\lambda^+} \sum_{\lambda \,:\, \lambda^+/\lambda \text{ is a horizontal } \mu_L\text{-strip}}} K_{\lambda,\overline{\mu}} s_{\lambda^+} = \sum_{\lambda^+} \sum_{\substack{\lambda \,:\, \lambda^+/\lambda \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda,\overline{\mu}} s_{\lambda^+}
\end{aligned}$$

$$= \sum_\lambda \sum_{\substack{\lambda^- \,:\, \lambda/\lambda^- \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda^-,\overline{\mu}} s_\lambda \tag{13.72.1}$$

$$\left(\text{here, we renamed the summation indices } \lambda^+ \text{ and } \lambda \text{ as } \lambda \text{ and } \lambda^-\right),$$

where all summation indices are supposed to be partitions.

Now, let us fix a partition λ. We shall show that

$$\sum_{\substack{\lambda^- \,:\, \lambda/\lambda^- \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda^-,\overline{\mu}} = K_{\lambda,\mu}. \tag{13.72.2}$$

Proof of (13.72.2)*:* For every partition λ^-, the number $K_{\lambda^-,\overline{\mu}}$ is the number of column-strict tableaux S of shape λ^- having $\operatorname{cont}(S) = \overline{\mu}$. Hence, the sum $\sum\limits_{\substack{\lambda^- \ : \ \lambda/\lambda^- \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda^-,\overline{\mu}}$ is the number of all pairs (λ^-, S), where:

- λ^- is a partition such that λ/λ^- is a horizontal μ_L-strip;
- S is a column-strict tableau of shape λ^- having $\operatorname{cont}(S) = \overline{\mu}$.

We will refer to such pairs (λ^-, S) as (λ, μ)-*last-step pairs*. So the sum $\sum\limits_{\substack{\lambda^- \ : \ \lambda/\lambda^- \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda^-,\overline{\mu}}$ is the number of (λ, μ)-last-step pairs. On the other hand, $K_{\lambda,\mu}$ is the number of all column-strict tableaux T of shape λ having $\operatorname{cont}(T) = \mu$. We now will construct a bijection between the (λ, μ)-last-step pairs and the column-strict tableaux T of shape λ having $\operatorname{cont}(T) = \mu$.

Indeed, let us first define a map Φ from the set of all (λ, μ)-last-step pairs to the set of all column-strict tableaux T of shape λ having $\operatorname{cont}(T) = \mu$. Namely, let (λ^-, S) be a (λ, μ)-last-step pair. Then, λ^- is a partition such that λ/λ^- is a horizontal μ_L-strip, whereas S is a column-strict tableau of shape λ^- having $\operatorname{cont}(S) = \overline{\mu}$. In particular, all entries of S are $< L$ (since $\operatorname{cont}(S) = \overline{\mu} = (\mu_1, \mu_2, \ldots, \mu_{L-1})$). Now, we can extend the column-strict tableau S of shape λ^- to a tableau of shape λ by filling the number L into all cells of the skew shape λ/λ^-. The resulting tableau is a column-strict tableau T of shape λ having $\operatorname{cont}(T) = \mu$ (indeed, its column-strictness follows from the fact that λ/λ^- is a horizontal μ_L-strip whereas all entries of S are $< L$; and the property $\operatorname{cont}(T) = \mu$ follows from the facts that $\operatorname{cont}(S) = \overline{\mu}$ and $|\lambda/\lambda^-| = \mu_L$). We define $\Phi(\lambda^-, S)$ to be this tableau. Thus we have defined a map Φ.

Conversely, let us define a map Ψ from the set of all column-strict tableaux T of shape λ having $\operatorname{cont}(T) = \mu$ to the set of all (λ, μ)-last-step pairs. Namely, let T be a column-strict tableau of shape λ having $\operatorname{cont}(T) = \mu$. Then, all entries of T are $\leq L$ (since $\operatorname{cont}(T) = \mu = (\mu_1, \mu_2, \ldots, \mu_L)$), and the cells containing the entries L form a horizontal strip (since T is column-strict). Hence, if we remove all entries L from T (along with their cells), the result will be a column-strict tableau S of some shape λ^- such that λ^- is a partition (because all entries of T were $\leq L$, so the entries we removed were maximal), λ/λ^- is a horizontal μ_L-strip (since we removed a total of μ_L entries and they formed a horizontal strip), and $\operatorname{cont}(S) = \overline{\mu}$. Consider these S and λ^-, and define $\Psi(T)$ to be the pair (λ^-, S); it is clear that this $\Psi(T)$ is a (λ, μ)-last-step pair. Hence, we have defined a map Ψ.

It is fairly obvious that the maps Φ and Ψ are mutually inverse. Hence, they are bijections; in particular, Φ is a bijection. Thus, we have a bijection between the set of all (λ, μ)-last-step pairs and the set of all column-strict tableaux T of shape λ having $\operatorname{cont}(T) = \mu$. As a consequence, the number of all (λ, μ)-last-step pairs equals the number of all column-strict tableaux T of shape λ having $\operatorname{cont}(T) = \mu$. In other words, $\sum\limits_{\substack{\lambda^- \ : \ \lambda/\lambda^- \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda^-,\overline{\mu}}$ equals $K_{\lambda,\mu}$ (because $\sum\limits_{\substack{\lambda^- \ : \ \lambda/\lambda^- \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda^-,\overline{\mu}}$ is the number of (λ, μ)-last-step pairs, whereas $K_{\lambda,\mu}$ is the number of all column-strict tableaux T of shape λ having $\operatorname{cont}(T) = \mu$). This proves (13.72.2).

Now, (13.72.1) becomes

$$h_\mu = \sum_\lambda \underbrace{\sum_{\substack{\lambda^- \ : \ \lambda/\lambda^- \text{ is a horizontal} \\ \mu_L\text{-strip}}} K_{\lambda^-,\overline{\mu}}}_{\substack{=K_{\lambda,\mu} \\ \text{(by (13.72.2))}}} s_\lambda = \sum_\lambda K_{\lambda,\mu} s_\lambda.$$

Hence, Exercise 2.7.10(a) is solved for our partition μ. Thus, Exercise 2.7.10(a) is solved for every partition μ satisfying $\ell(\mu) = L$. This completes the induction step, and thus Exercise 2.7.10(a) is solved by induction.

(b) Let us work in the power series ring $\mathbf{k}[[\mathbf{x}, \mathbf{y}]] := \mathbf{k}[[x_1, x_2, \ldots, y_1, y_2, \ldots]]$. Every partition μ satisfies $h_\mu(\mathbf{x}) = \sum_\lambda K_{\lambda,\mu} s_\lambda(\mathbf{x})$, where the sum ranges over all partitions λ (because Exercise 2.7.10(a) yields $h_\mu = \sum_\lambda K_{\lambda,\mu} s_\lambda$ in Λ). In other words, every partition μ satisfies $h_\mu(\mathbf{x}) = \sum_{\lambda \in \mathrm{Par}} K_{\lambda,\mu} s_\lambda(\mathbf{x})$. On the other hand, every partition λ satisfies $s_\lambda = \sum_\mu K_{\lambda,\mu} m_\mu$, where the sum ranges over all partitions μ (this was shown in the proof of Proposition 2.2.10). In other words, every partition λ satisfies $s_\lambda = \sum_{\mu \in \mathrm{Par}} K_{\lambda,\mu} m_\mu$,

so that

$$s_\lambda(\mathbf{y}) = \sum_{\mu\in\mathrm{Par}} K_{\lambda,\mu} m_\mu(\mathbf{y}) . \tag{13.72.3}$$

Now,

$$\begin{aligned}
\prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1} &= \sum_{\lambda\in\mathrm{Par}} h_\lambda(\mathbf{x}) m_\lambda(\mathbf{y}) \qquad (\text{by } (2.5.11)) \\
&= \sum_{\mu\in\mathrm{Par}} \underbrace{h_\mu(\mathbf{x})}_{=\sum_{\lambda\in\mathrm{Par}} K_{\lambda,\mu} s_\lambda(\mathbf{x})} m_\mu(\mathbf{y}) \qquad (\text{here, we renamed the summation index } \lambda \text{ as } \mu) \\
&= \underbrace{\sum_{\mu\in\mathrm{Par}} \sum_{\lambda\in\mathrm{Par}}}_{=\sum_{\lambda\in\mathrm{Par}} \sum_{\mu\in\mathrm{Par}}} K_{\lambda,\mu} s_\lambda(\mathbf{x}) m_\mu(\mathbf{y}) \\
&= \sum_{\lambda\in\mathrm{Par}} \sum_{\mu\in\mathrm{Par}} K_{\lambda,\mu} s_\lambda(\mathbf{x}) m_\mu(\mathbf{y}) = \sum_{\lambda\in\mathrm{Par}} s_\lambda(\mathbf{x}) \underbrace{\sum_{\mu\in\mathrm{Par}} K_{\lambda,\mu} m_\mu(\mathbf{y})}_{\substack{=s_\lambda(\mathbf{y}) \\ (\text{by } (13.72.3))}} \\
&= \sum_{\lambda\in\mathrm{Par}} s_\lambda(\mathbf{x}) s_\lambda(\mathbf{y}) .
\end{aligned}$$

This proves Theorem 2.5.1. Thus, Exercise 2.7.10(b) is solved.

(c) We start out just as in the proof of Proposition 2.2.10: We fix an $n \in \mathbb{N}$, and we restrict our attention to a given homogeneous component Λ_n and partitions of n. Regard the set Par_n as a poset with smaller-or-equal relation $\triangleright$. We will check that the family $(h_\lambda)_{\lambda\in\mathrm{Par}_n}$ expands unitriangularly[618] in the basis $(s_\lambda)_{\lambda\in\mathrm{Par}_n}$.

If λ and μ are two partitions satisfying $|\lambda| \neq |\mu|$, then

$$K_{\lambda,\mu} = 0 \tag{13.72.4}$$

(because $K_{\lambda,\mu}$ counts the column-strict tableaux T of shape λ having $\mathrm{cont}(T) = \mu$; but no such tableaux exist when $|\lambda| \neq |\mu|$).

In Exercise 2.7.10(a), we have shown that $h_\mu = \sum_{\lambda\in\mathrm{Par}} K_{\lambda,\mu} s_\lambda$ for every $\mu \in \mathrm{Par}$. Thus, for every $\mu \in \mathrm{Par}_n$, we have

$$\begin{aligned}
h_\mu = \sum_{\lambda\in\mathrm{Par}} K_{\lambda,\mu} s_\lambda &= \underbrace{\sum_{\substack{\lambda\in\mathrm{Par}; \\ |\lambda|=n}}}_{=\sum_{\lambda\in\mathrm{Par}_n}} K_{\lambda,\mu} s_\lambda + \sum_{\substack{\lambda\in\mathrm{Par}; \\ |\lambda|\neq n}} \underbrace{K_{\lambda,\mu}}_{\substack{=0 \\ (\text{by } (13.72.4), \text{ since } |\lambda|\neq n=|\mu|)}} s_\lambda \\
&= \sum_{\lambda\in\mathrm{Par}_n} K_{\lambda,\mu} s_\lambda + \underbrace{\sum_{\substack{\lambda\in\mathrm{Par}; \\ |\lambda|\neq n}} 0 s_\lambda}_{=0} = \sum_{\lambda\in\mathrm{Par}_n} K_{\lambda,\mu} s_\lambda .
\end{aligned} \tag{13.72.5}$$

In the proof of Proposition 2.2.10, we showed that any two partitions λ and μ in Par_n satisfy $K_{\lambda,\mu} = 0$ unless $\lambda \triangleright \mu$. Hence, the $\mathrm{Par}_n \times \mathrm{Par}_n$-matrix $(K_{\lambda,\mu})_{(\mu,\lambda)\in\mathrm{Par}_n\times\mathrm{Par}_n}$ is triangular[619]. This matrix is furthermore unitriangular (since $K_{\lambda,\lambda} = 1$ for every partition λ, as shown in the proof of Proposition 2.2.10), and therefore invertibly triangular. But the family $(h_\lambda)_{\lambda\in\mathrm{Par}_n}$ expands in the family $(s_\lambda)_{\lambda\in\mathrm{Par}_n}$ through this matrix $(K_{\lambda,\mu})_{(\mu,\lambda)\in\mathrm{Par}_n\times\mathrm{Par}_n}$ (because of (13.72.5)). Therefore, the family $(h_\lambda)_{\lambda\in\mathrm{Par}_n}$ expands invertibly triangularly in the family $(s_\lambda)_{\lambda\in\mathrm{Par}_n}$ (since our matrix is invertibly triangular). Hence, Corollary 11.1.19(e) (applied to Λ_n, Par_n, $(h_\lambda)_{\lambda\in\mathrm{Par}_n}$ and $(s_\lambda)_{\lambda\in\mathrm{Par}_n}$ instead of M, S, $(e_s)_{s\in S}$ and $(f_s)_{s\in S}$) shows that the family $(h_\lambda)_{\lambda\in\mathrm{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n if and only if the family $(s_\lambda)_{\lambda\in\mathrm{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n. Therefore, the family $(h_\lambda)_{\lambda\in\mathrm{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n (since the family $(s_\lambda)_{\lambda\in\mathrm{Par}_n}$ is a basis of the

[618] See Definition 11.1.16(c) for what this means.

[619] See Definition 11.1.7 for the meaning of this.

k-module Λ_n). Since this has been proven for all $n \in \mathbb{N}$, we can combine this to conclude that the family $(h_\lambda)_{\lambda \in \mathrm{Par}}$ is a graded basis of the graded **k**-module Λ. This solves Exercise 2.7.10(c).

Remark. Just as in the Remark after the solution of Exercise 2.5.20(b), we can use our solution of Exercise 2.7.10(c) to further prove that $(e_\lambda)_{\lambda \in \mathrm{Par}}$ is a **k**-basis of Λ (in a different way than we have done in the proof of Proposition 2.2.10).

13.73. **Solution to Exercise 2.7.11.** *Solution to Exercise 2.7.11.* Let us first observe that

$$\mathfrak{z}(h_n) = e_n \qquad \text{for every positive integer } n. \tag{13.73.1}$$

(In fact, $h_n = s_{(n)}$, and so the map $\mathfrak{z}$ maps h_n to $s_{(n)^t} = s_{(1^n)} = e_n$.)

(a) Fix $n \in \mathbb{N}$. We need to prove that

$$\mathfrak{z}(f h_n) = \mathfrak{z}(f) \cdot \mathfrak{z}(h_n) \qquad \text{for every } f \in \Lambda. \tag{13.73.2}$$

Since this equality is linear in f, it is clearly enough to prove it when f is of the form s_λ for some $\lambda \in \mathrm{Par}$ (because $(s_\lambda)_{\lambda \in \mathrm{Par}}$ is a **k**-basis of Λ). In other words, it is enough to show that every $\lambda \in \mathrm{Par}$ satisfies

$$\mathfrak{z}(s_\lambda h_n) = \mathfrak{z}(s_\lambda) \cdot \mathfrak{z}(h_n). \tag{13.73.3}$$

Thus, we will focus on proving (13.73.3) now.

We WLOG assume that $n \neq 0$, since otherwise (13.73.3) is obvious. Let $\lambda \in \mathrm{Par}$. The equality (2.7.1) yields

$$s_\lambda h_n = \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{\lambda^+}.$$

Applying the map $\mathfrak{z}$ to both sides of this equality, we obtain

$$\mathfrak{z}(s_\lambda h_n) = \mathfrak{z}\left(\sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{\lambda^+} \right) = \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} \underbrace{\mathfrak{z}(s_{\lambda^+})}_{= s_{(\lambda^+)^t}} = \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{(\lambda^+)^t}. \tag{13.73.4}$$

However, for any given partition λ^+, the assertion that λ^+/λ be a horizontal n-strip is equivalent to the assertion that $(\lambda^+)^t/\lambda^t$ be a vertical n-strip[620]. Hence, we can replace the summation sign "$\sum\limits_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}}$" in (13.73.4) by a "$\sum\limits_{\substack{\lambda^+ \,:\, (\lambda^+)^t/\lambda^t \text{ is a} \\ \text{vertical } n\text{-strip}}}$" sign. Thus, we obtain

$$\sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{(\lambda^+)^t} = \sum_{\substack{\lambda^+ \,:\, (\lambda^+)^t/\lambda^t \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{(\lambda^+)^t} = \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda^t \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+}$$

$$\left(\begin{array}{c} \text{here, we substituted } \lambda^+ \text{ for } (\lambda^+)^t \text{ in the sum, because} \\ \text{the map } \mathrm{Par} \to \mathrm{Par},\ \mu \mapsto \mu^t \text{ is a bijection} \end{array} \right).$$

Thus, (13.73.4) becomes

$$\mathfrak{z}(s_\lambda h_n) = \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{(\lambda^+)^t} = \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda^t \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+}. \tag{13.73.5}$$

On the other hand, the equality (2.7.2) yields

$$s_\lambda e_n = \sum_{\substack{\lambda^+ \,:\, \lambda^+/\lambda \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+}.$$

[620] This is because the notion of a vertical n-strip is obtained from the notion of a horizontal n-strip by interchanging the roles of rows and columns, and the operation which sends a partition μ to its transpose partition μ^t interchanges the roles of rows and columns as well.

Applying this to λ^t instead of λ, we obtain

$$s_{\lambda^t} e_n = \sum_{\substack{\lambda^+ \ : \ \lambda^+/\lambda^t \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+}.$$

Now,

$$\underbrace{\mathfrak{Z}\left(s_\lambda\right)}_{=s_{\lambda^t}} \cdot \underbrace{\mathfrak{Z}\left(h_n\right)}_{=e_n} = s_{\lambda^t} e_n = \sum_{\substack{\lambda^+ \ : \ \lambda^+/\lambda^t \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+}.$$

Compared with (13.73.5), this yields $\mathfrak{Z}\left(s_\lambda h_n\right) = \mathfrak{Z}\left(s_\lambda\right) \cdot \mathfrak{Z}\left(h_n\right)$. This proves (13.73.3). This concludes the solution of Exercise 2.7.11(a).

(b) We shall show that

$$\mathfrak{Z}\left(h_\lambda\right) = \omega\left(h_\lambda\right) \qquad \text{for every partition } \lambda. \tag{13.73.6}$$

Proof of (13.73.6)*:* We will prove (13.73.6) by induction over $\ell\left(\lambda\right)$. The *induction base* is the case $\ell\left(\lambda\right) = 0$, which is utterly obvious. For the *induction step*, we fix a positive integer L and assume (as the induction hypothesis) that the equality (13.73.6) holds if $\ell\left(\lambda\right) = L - 1$. We need to prove that the equality (13.73.6) holds if $\ell\left(\lambda\right) = L$.

Let λ be a partition satisfying $\ell\left(\lambda\right) = L$. Write λ in the form $\lambda = \left(\lambda_1, \lambda_2, ..., \lambda_L\right)$ with all of λ_1, λ_2, ..., λ_L being positive integers. Let $\overline{\lambda}$ be the partition $\left(\lambda_1, \lambda_2, ..., \lambda_{L-1}\right)$ (this is obviously well-defined); then, $\ell\left(\overline{\lambda}\right) = L - 1$.

Recall that $e_n = \omega\left(h_n\right)$ for every $n \geq 1$ (by Proposition 2.4.3(b)).

Recall that $\lambda = \left(\lambda_1, \lambda_2, ..., \lambda_L\right)$. Hence, by the definition of h_λ, we have

$$h_\lambda = h_{\lambda_1} h_{\lambda_2} ... h_{\lambda_L} = \underbrace{h_{\lambda_1} h_{\lambda_2} ... h_{\lambda_{L-1}}}_{\substack{= h_{\overline{\lambda}} \\ \left(\text{since } \overline{\lambda} = \left(\lambda_1, \lambda_2, ..., \lambda_{L-1}\right)\right)}} h_{\lambda_L} = h_{\overline{\lambda}} h_{\lambda_L}.$$

Applying the map $\mathfrak{Z}$ to both sides of this equality, we obtain

$$\begin{aligned}
\mathfrak{Z}\left(h_\lambda\right) = \mathfrak{Z}\left(h_{\overline{\lambda}} h_{\lambda_L}\right) &= \underbrace{\mathfrak{Z}\left(h_{\overline{\lambda}}\right)}_{\substack{= \omega\left(h_{\overline{\lambda}}\right) \\ \text{(by the induction} \\ \text{hypothesis,} \\ \text{since } \ell\left(\overline{\lambda}\right) = L-1)}} \cdot \underbrace{\mathfrak{Z}\left(h_{\lambda_L}\right)}_{\substack{= e_{\lambda_L} \\ \text{(by (13.73.1))}}} \\
&\qquad \left(\text{by Exercise 2.7.11(a), applied to } h_{\overline{\lambda}} \text{ and } \lambda_L \text{ instead of } f \text{ and } n\right) \\
&= \omega\left(h_{\overline{\lambda}}\right) \cdot \underbrace{e_{\lambda_L}}_{\substack{= \omega\left(h_{\lambda_L}\right) \\ \text{(since } e_n = \omega\left(h_n\right) \\ \text{for every } n \geq 1)}} = \omega\left(h_{\overline{\lambda}}\right) \cdot \omega\left(h_{\lambda_L}\right) = \omega\left(\underbrace{h_{\overline{\lambda}} h_{\lambda_L}}_{= h_\lambda}\right) \qquad \text{(since } \omega \text{ is a } \mathbf{k}\text{-algebra morphism)} \\
&= \omega\left(h_\lambda\right).
\end{aligned}$$

In other words, the equality (13.73.6) holds if $\ell\left(\lambda\right) = L$. This completes the induction step. The induction proof of (13.73.6) is therefore complete.

The equality (13.73.6) shows that the $\mathbf{k}$-linear maps $\mathfrak{Z} : \Lambda \to \Lambda$ and $\omega : \Lambda \to \Lambda$ are equal to each other on every element of the basis $\left(h_\lambda\right)_{\lambda \in \mathrm{Par}}$ of the $\mathbf{k}$-module Λ. Hence, $\mathfrak{Z} = \omega$. This solves Exercise 2.7.11(b).

(c) Fix two partitions μ and ν. Then, (2.5.6) yields

$$s_\mu s_\nu = \sum_{\lambda \in \mathrm{Par}} c^\lambda_{\mu,\nu} s_\lambda. \tag{13.73.7}$$

Applying this to μ^t and ν^t instead of μ and ν, we obtain

$$s_{\mu^t} s_{\nu^t} = \sum_{\lambda \in \mathrm{Par}} c^\lambda_{\mu^t,\nu^t} s_\lambda. \tag{13.73.8}$$

Applying the map $\mathfrak{Z}$ to the identity (13.73.7), we obtain

$$\begin{aligned}
\mathfrak{Z}(s_\mu s_\nu) &= \mathfrak{Z}\left(\sum_{\lambda\in\operatorname{Par}} c^{\lambda}_{\mu,\nu} s_\lambda\right) = \sum_{\lambda\in\operatorname{Par}} c^{\lambda}_{\mu,\nu} \underbrace{\mathfrak{Z}(s_\lambda)}_{=s_{\lambda^t}} \\
&= \sum_{\lambda\in\operatorname{Par}} \underbrace{c^{\lambda}_{\mu,\nu}}_{\substack{=c^{(\lambda^t)^t}_{\mu,\nu} \\ (\text{since } \lambda=(\lambda^t)^t)}} s_{\lambda^t} = \sum_{\lambda\in\operatorname{Par}} c^{(\lambda^t)^t}_{\mu,\nu} s_{\lambda^t} = \sum_{\lambda\in\operatorname{Par}} c^{\lambda^t}_{\mu,\nu} s_\lambda \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } \lambda \text{ for } \lambda^t \text{ in the sum, since} \\ \text{the map } \operatorname{Par}\to\operatorname{Par},\ \lambda\mapsto\lambda^t \text{ is a bijection}\end{array}\right).
\end{aligned} \tag{13.73.9}$$

But recall that ω is a **k**-algebra homomorphism. Since $\mathfrak{Z}=\omega$ (by Exercise 2.7.11(b)), this shows that $\mathfrak{Z}$ is a **k**-algebra homomorphism. Hence,

$$\mathfrak{Z}(s_\mu s_\nu) = \underbrace{\mathfrak{Z}(s_\mu)}_{=s_{\mu^t}} \cdot \underbrace{\mathfrak{Z}(s_\nu)}_{=s_{\nu^t}} = s_{\mu^t} s_{\nu^t} = \sum_{\lambda\in\operatorname{Par}} c^{\lambda}_{\mu^t,\nu^t} s_\lambda \qquad (\text{by } (13.73.8)).$$

Compared with (13.73.9), this yields $\sum_{\lambda\in\operatorname{Par}} c^{\lambda^t}_{\mu,\nu} s_\lambda = \sum_{\lambda\in\operatorname{Par}} c^{\lambda}_{\mu^t,\nu^t} s_\lambda$. Since $(s_\lambda)_{\lambda\in\operatorname{Par}}$ is a basis of the **k**-module Λ, we can compare coefficients in this equality, and obtain

$$c^{\lambda^t}_{\mu,\nu} = c^{\lambda}_{\mu^t,\nu^t} \qquad \text{for every } \lambda\in\operatorname{Par}. \tag{13.73.10}$$

We can substitute λ^t for λ in this result, and conclude that $c^{(\lambda^t)^t}_{\mu,\nu} = c^{\lambda^t}_{\mu^t,\nu^t}$ for every $\lambda\in\operatorname{Par}$. Since $(\lambda^t)^t=\lambda$, this rewrites as $c^{\lambda}_{\mu,\nu} = c^{\lambda^t}_{\mu^t,\nu^t}$. This solves Exercise 2.7.11(c).

(d) Let μ and λ be two partitions such that $\mu\subseteq\lambda$. In Remark 2.5.9, it has been shown that $s_{\lambda/\mu} = \sum_\nu c^{\lambda}_{\mu,\nu} s_\nu$, where the sum ranges over all partitions ν. In other words,

$$s_{\lambda/\mu} = \sum_{\nu\in\operatorname{Par}} c^{\lambda}_{\mu,\nu} s_\nu. \tag{13.73.11}$$

Applying this to λ^t and μ^t instead of λ and μ, we obtain

$$s_{\lambda^t/\mu^t} = \sum_{\nu\in\operatorname{Par}} c^{\lambda^t}_{\mu^t,\nu} s_\nu. \tag{13.73.12}$$

Applying the map $\mathfrak{Z}$ to both sides of the identity (13.73.11), we obtain

$$\begin{aligned}
\mathfrak{Z}(s_{\lambda/\mu}) &= \mathfrak{Z}\left(\sum_{\nu\in\operatorname{Par}} c^{\lambda}_{\mu,\nu} s_\nu\right) = \sum_{\nu\in\operatorname{Par}} \underbrace{c^{\lambda}_{\mu,\nu}}_{\substack{=c^{\lambda^t}_{\mu^t,\nu^t} \\ (\text{by Exercise 2.7.11(c)})}} \underbrace{\mathfrak{Z}(s_\nu)}_{=s_{\nu^t}} = \sum_{\nu\in\operatorname{Par}} c^{\lambda^t}_{\mu^t,\nu^t} s_{\nu^t} = \sum_{\nu\in\operatorname{Par}} c^{\lambda^t}_{\mu^t,\nu} s_\nu \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } \nu \text{ for } \nu^t \text{ in the sum, since} \\ \text{the map } \operatorname{Par}\to\operatorname{Par},\ \nu\mapsto\nu^t \text{ is a bijection}\end{array}\right) \\
&= s_{\lambda^t/\mu^t} \qquad (\text{by } (13.73.12)).
\end{aligned}$$

Since $\mathfrak{Z}=\omega$ (by Exercise 2.7.11(b)), this rewrites as $\omega(s_{\lambda/\mu}) = s_{\lambda^t/\mu^t}$. This proves the first identity of (2.4.15).

It is clear that the skew Schur function $s_{\lambda/\mu}$ is homogeneous of degree $|\lambda/\mu|$. In other words, $s_{\lambda/\mu}\in\Lambda_{|\lambda/\mu|}$. Hence, (2.4.11) (applied to $f=s_{\lambda/\mu}$ and $n=|\lambda/\mu|$) yields

$$S(s_{\lambda/\mu}) = (-1)^{|\lambda/\mu|} \underbrace{\omega(s_{\lambda/\mu})}_{=s_{\lambda^t/\mu^t}} = (-1)^{|\lambda/\mu|} s_{\lambda^t/\mu^t}.$$

This proves the second identity of (2.4.15). The proof of (2.4.15) is thus complete.

13.74. **Solution to Exercise 2.7.12.** *Solution to Exercise 2.7.12.* (a)

First solution to Exercise 2.7.12(a): Let us first show that $\prod_{i,j=1}^{\infty}(1+x_iy_j) = \sum_{\lambda\in\mathrm{Par}} e_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y})$.

In fact, in the proof of Proposition 2.5.15, we showed that $\prod_{j=1}^{\infty}\sum_{n\geq 0} h_n(\mathbf{x})\, y_j^n = \sum_{\lambda\in\mathrm{Par}} h_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y})$. The same argument (with all appearances of the letter "h" replaced by the letter "e") shows that

$$\prod_{j=1}^{\infty}\sum_{n\geq 0} e_n(\mathbf{x})\, y_j^n = \sum_{\lambda\in\mathrm{Par}} e_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y}). \tag{13.74.1}$$

But (2.2.19) yields

$$\prod_{i=1}^{\infty}(1+x_it) = \sum_{n\geq 0} e_n(\mathbf{x})\, t^n \tag{13.74.2}$$

in the ring $(\mathbf{k}[[\mathbf{x}]])[[t]]$. For every $j\in\{1,2,3,\ldots\}$, we have

$$\prod_{i=1}^{\infty}(1+x_iy_j) = \sum_{n\geq 0} e_n(\mathbf{x})\, y_j^n \tag{13.74.3}$$

in the ring $(\mathbf{k}[[\mathbf{x}]])[[\mathbf{y}]]$ (in fact, this results from (13.74.2) by substituting y_j for t). Thus, (13.74.3) holds in $\mathbf{k}[[\mathbf{x},\mathbf{y}]]$ (since $(\mathbf{k}[[\mathbf{x}]])[[\mathbf{y}]] = \mathbf{k}[[\mathbf{x},\mathbf{y}]]$ as rings). Now,

$$\underbrace{\prod_{i,j=1}^{\infty}}_{=\prod_{j=1}^{\infty}\prod_{i=1}^{\infty}}(1+x_iy_j) = \prod_{j=1}^{\infty}\underbrace{\prod_{i=1}^{\infty}(1+x_iy_j)}_{\substack{=\sum_{n\geq 0}e_n(\mathbf{x})y_j^n \\ \text{(by (13.74.3))}}} = \prod_{j=1}^{\infty}\sum_{n\geq 0} e_n(\mathbf{x})\, y_j^n$$

$$= \sum_{\lambda\in\mathrm{Par}} e_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y}) \qquad (\text{by (13.74.1)}). \tag{13.74.4}$$

Next, we shall show that $\sum_{\lambda\in\mathrm{Par}} s_\lambda(\mathbf{x})\, s_{\lambda^t}(\mathbf{y}) = \sum_{\lambda\in\mathrm{Par}} e_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y})$.

In fact, consider the $\mathbf{k}$-algebra $(\mathbf{k}[[\mathbf{x}]])[[\mathbf{y}]] = \mathbf{k}[[\mathbf{x},\mathbf{y}]]$. This $\mathbf{k}$-algebra $(\mathbf{k}[[\mathbf{x}]])[[\mathbf{y}]]$ is a $\mathbf{k}[[\mathbf{y}]]$-algebra, and contains $\Lambda[[\mathbf{y}]]$ as a $\mathbf{k}[[\mathbf{y}]]$-subalgebra.

The equality (2.5.1) yields

$$\sum_{\lambda\in\mathrm{Par}} s_\lambda(\mathbf{x})\, s_\lambda(\mathbf{y}) = \prod_{i,j=1}^{\infty}(1-x_iy_j)^{-1} = \sum_{\lambda\in\mathrm{Par}} h_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y}) \qquad (\text{by (2.5.11)}). \tag{13.74.5}$$

This is an equality in $\Lambda[[\mathbf{y}]]$ (because $s_\lambda(\mathbf{x})$ and $h_\lambda(\mathbf{x})$ belong to Λ for every $\lambda\in\mathrm{Par}$).

Recall that $\omega:\Lambda\to\Lambda$ is a $\mathbf{k}$-algebra homomorphism. It thus induces a $\mathbf{k}[[\mathbf{y}]]$-algebra homomorphism $\omega[[\mathbf{y}]]:\Lambda[[\mathbf{y}]]\to\Lambda[[\mathbf{y}]]$ which sends every $q\in\Lambda$ to $\omega(q)$, and is continuous with respect to the usual topology[621] on $\Lambda[[\mathbf{y}]]$. Applying this homomorphism $\omega[[\mathbf{y}]]$ to both sides of (13.74.5), we obtain

$$\sum_{\lambda\in\mathrm{Par}} \omega(s_\lambda(\mathbf{x}))\, s_\lambda(\mathbf{y}) = \sum_{\lambda\in\mathrm{Par}} \omega(h_\lambda(\mathbf{x}))\, m_\lambda(\mathbf{y}) \tag{13.74.6}$$

(because $\omega[[\mathbf{y}]]$, being a $\mathbf{k}[[\mathbf{y}]]$-algebra homomorphism, leaves the $s_\lambda(\mathbf{y})$ and $m_\lambda(\mathbf{y})$ terms unchanged, while the $s_\lambda(\mathbf{x})$ and $h_\lambda(\mathbf{x})$ terms are elements of Λ and thus are transformed as by ω).

But we know that

$$\omega(s_\lambda) = s_{\lambda^t} \qquad \text{for every partition } \lambda. \tag{13.74.7}$$

(This follows from the first equality in (2.4.15) by setting $\mu=\varnothing$.) Using (2.4.12) and (13.74.7), we can rewrite (13.74.6) as

$$\sum_{\lambda\in\mathrm{Par}} s_{\lambda^t}(\mathbf{x})\, s_\lambda(\mathbf{y}) = \sum_{\lambda\in\mathrm{Par}} e_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y}).$$

[621] The usual topology on a power series ring $Z[[\mathbf{y}]]$ (where Z is a commutative ring) is the direct-product topology obtained by viewing the set $Z[[\mathbf{y}]]$ as a direct product of many copies of Z (this is done by identifying every power series with the family of its coefficients), each of which is endowed with the discrete topology. In this topology, a sequence (or, more generally, a net) $(f_i)_i$ of power series converges to a power series f if and only if for every monomial $\mathfrak{m}$, the sequence (resp. net) (the coefficient of $\mathfrak{m}$ in $f_i)_i$ converges to (the coefficient of $\mathfrak{m}$ in f) with respect to the discrete topology. (The notion of a *net* is a generalization of the notion of a sequence; it is useful in topology. See [219] for an introduction to it.)

Hence,

$$\sum_{\lambda\in\operatorname{Par}} e_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y}) = \sum_{\lambda\in\operatorname{Par}} s_{\lambda^t}(\mathbf{x})\, s_\lambda(\mathbf{y}) = \sum_{\lambda\in\operatorname{Par}} \underbrace{s_{(\lambda^t)^t}(\mathbf{x})}_{\substack{=s_\lambda(\mathbf{x}) \\ (\text{since } (\lambda^t)^t=\lambda)}} s_{\lambda^t}(\mathbf{y})$$

$$\left(\begin{array}{c}\text{here, we substituted } \lambda^t \text{ for } \lambda \text{ in the sum, since the map} \\ \operatorname{Par}\to\operatorname{Par},\ \lambda\mapsto\lambda^t \text{ is a bijection}\end{array}\right)$$

$$= \sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x})\, s_{\lambda^t}(\mathbf{y}). \tag{13.74.8}$$

Combined with (13.74.4), this yields

$$\prod_{i,j=1}^{\infty}(1+x_iy_j) = \sum_{\lambda\in\operatorname{Par}} e_\lambda(\mathbf{x})\, m_\lambda(\mathbf{y}) = \sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x})\, s_{\lambda^t}(\mathbf{y}). \tag{13.74.9}$$

This solves Exercise 2.7.12(a).

Second solution to Exercise 2.7.12(a): We can prove (13.74.4) as in the First solution to Exercise 2.7.12(a). Thus, in order to solve Exercise 2.7.12(a), it remains to verify

$$\prod_{i,j=1}^{\infty}(1+x_iy_j) = \sum_{\lambda\in\operatorname{Par}} s_\lambda(\mathbf{x})\, s_{\lambda^t}(\mathbf{y}). \tag{13.74.10}$$

Instead of proving (13.74.10), we will verify the identity

$$\prod_{i,j=1}^{\infty}(1+tx_iy_j) = \sum_{\lambda\in\operatorname{Par}} t^{|\lambda|} s_\lambda(\mathbf{x})\, s_{\lambda^t}(\mathbf{y}) \tag{13.74.11}$$

in the ring $R(\mathbf{x},\mathbf{y})[[t]]$. This identity will clearly yield (13.74.10) (by substituting $t=1$), and thus conclude the solution of Exercise 2.7.12(a).

We shall prove (13.74.11) in a similar way to how we proved (2.5.2), but using a variation on the RSK correspondence. This is not in itself a new idea; indeed, this is how the equivalent identity (13.74.10) is proven in [206, Theorem 7.14.3], in [111, §7] and in [186, Theorem 4.8.6]. However, instead of using the dual RSK algorithm (also known as the RSK* algorithm; see [206, §7.14], [111, §5] and [186, Theorem 4.8.5] for it) like these proofs do, we introduce a variation of the RSK algorithm that relies on the same RS-insertion operation but changes the order in which the biletters are processed. (We will reprove (13.74.11) using the dual RSK algorithm in the Third solution further below.)

For a given partition λ, let us define a *row-strict tableau* of shape λ to be an assignment T of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram for λ which is strictly increasing left-to-right in rows, and weakly increasing top-to-bottom in columns. It is clear that if λ is a partition, then the row-strict tableaux of shape λ are in 1-to-1 correspondence with the column-strict tableaux of shape λ^t, and the correspondence is given by transposing the tableau (i.e., taking whatever entry was assigned to a cell (i,j) in the input tableau, and reassigning it to the cell (j,i) in the output tableau). Hence, for every partition λ, we have

$$\sum_{\substack{Q \text{ is a row-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(Q)} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda^t}} \mathbf{x}^{\operatorname{cont}(T)}$$

$$= s_{\lambda^t} \qquad (\text{since this is how } s_{\lambda^t} \text{ is defined}) \tag{13.74.12}$$

(where $\mathbf{x}^{\operatorname{cont}(Q)}$ is defined for a row-strict tableau Q in the same way as it is defined for a column-strict tableau Q). Substituting $\mathbf{y}$ for $\mathbf{x}$ in this equality, we obtain

$$\sum_{\substack{Q \text{ is a row-strict} \\ \text{tableau of shape } \lambda}} \mathbf{y}^{\operatorname{cont}(Q)} = s_{\lambda^t}(\mathbf{y}). \tag{13.74.13}$$

We also have

$$\sum_{\substack{P \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(P)} = s_\lambda(\mathbf{x}) \tag{13.74.14}$$

(because this is how $s_\lambda = s_\lambda(\mathbf{x})$ is defined) for every partition λ.

A *tableau-cotableau pair* will mean a pair (P, Q) such that P is a column-strict tableau, Q is a row-strict tableau, and P and Q both have shape λ for one and the same partition λ. Multiplying the identities (13.74.14) and (13.74.13) and multiplying the result with $t^{|\lambda|}$, we obtain

$$t^{|\lambda|} \sum_{\substack{(P,Q) \text{ is a pair with} \\ P \text{ being a column-strict tableau} \\ \text{of shape } \lambda, \text{ and } Q \text{ being} \\ \text{a row-strict tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(P)} \mathbf{y}^{\operatorname{cont}(Q)} = t^{|\lambda|} s_\lambda(\mathbf{x}) s_{\lambda^t}(\mathbf{y})$$

for every partition λ. Summing this equality over all partitions λ, we obtain

$$\sum t^{|\lambda|} \mathbf{x}^{\operatorname{cont}(P)} \mathbf{y}^{\operatorname{cont}(Q)} = \sum_{\lambda \in \operatorname{Par}} t^{|\lambda|} s_\lambda(\mathbf{x}) s_{\lambda^t}(\mathbf{y}), \tag{13.74.15}$$

where the sum on the left hand side is over all tableau-cotableau pairs (P, Q) and where λ denotes the common shape of P and Q.

We shall use all notations introduced in the proof of Theorem 2.5.1. Define the *antilexicographic order* $\leq_{alex}$ to be the total order on the set of all biletters which is given by

$$\binom{i_1}{j_1} \leq_{alex} \binom{i_2}{j_2} \iff (\text{we have } i_1 \leq i_2, \text{ and if } i_1 = i_2, \text{ then } j_1 \geq j_2).$$

We denote by $<_{alex}$ the (strict) smaller relation of this order. A *strict cobiword* will mean an array $\binom{\mathbf{i}}{\mathbf{j}} = \binom{i_1 \ldots i_\ell}{j_1 \ldots j_\ell}$ in which the biletters satisfy $\binom{i_1}{j_1} <_{alex} \cdots <_{alex} \binom{i_\ell}{j_\ell}$ (that is, the biletters are distinct and ordered). Strict cobiwords are clearly in 1-to-1 correspondence with sets (not multisets!) of biletters. Now, the left hand side of (13.74.11) is $\prod_{i,j=1}^{\infty}(1 + t x_i y_j) = \prod_{i,j=1}^{\infty}(1 + t x_j y_i)$ (here, we substituted (j, i) for the index (i, j) in the product), and thus can be rewritten as the sum of $t^\ell (x_{j_1} y_{i_1})(x_{j_2} y_{i_2}) \cdots (x_{j_\ell} y_{i_\ell})$ over all sets $\left\{\binom{i_1}{j_1}, \ldots, \binom{i_\ell}{j_\ell}\right\}$ of biletters. Thus, the left hand side of (13.74.11) is the sum $\sum t^\ell \mathbf{x}^{\operatorname{cont}(\mathbf{j})} \mathbf{y}^{\operatorname{cont}(\mathbf{i})}$ over all strict cobiwords $\binom{\mathbf{i}}{\mathbf{j}}$, where ℓ stands for the number of biletters in the strict cobiword. Meanwhile, we know that the right hand side of (13.74.11) is the sum $\sum t^{|\lambda|} \mathbf{x}^{\operatorname{cont}(P)} \mathbf{y}^{\operatorname{cont}(Q)}$ over all tableau-cotableau pairs (P, Q) (because of (13.74.15)). Thus, in order to prove (13.74.11), we only need to construct a bijection between the strict cobiwords $\binom{\mathbf{i}}{\mathbf{j}}$ and the tableau-cotableau pairs (P, Q), which has the property that

$$\operatorname{cont}(\mathbf{i}) = \operatorname{cont}(Q);$$
$$\operatorname{cont}(\mathbf{j}) = \operatorname{cont}(P).$$

[622]

This bijection is the *coRSK algorithm*, which we shall now define.[623]

Let $\binom{\mathbf{i}}{\mathbf{j}}$ be a strict cobiword. Starting with the pair $(P_0, Q_0) = (\varnothing, \varnothing)$ and $m = 0$, the algorithm applies the following steps (see Example 13.74.1 below):

- If i_{m+1} does not exist (that is, m is the length of $\mathbf{i}$), stop.
- Apply RS-insertion to the column-strict tableau P_m and the letter j_{m+1} (the bottom letter of $\binom{i_{m+1}}{j_{m+1}}$). Let P_{m+1} be the resulting column-strict tableau, and let c_{m+1} be the resulting corner cell.
- Create Q_{m+1} from Q_m by adding the top letter i_{m+1} of $\binom{i_{m+1}}{j_{m+1}}$ to Q_m in the cell c_{m+1} (which, as we recall, is the extra corner cell of P_{m+1} not present in P_m).
- Set m to $m + 1$.

After all of the biletters have been thus processed, the result of the coRSK algorithm is $(P_\ell, Q_\ell) =: (P, Q)$.

Example 13.74.1. The term in the expansion of the left side of (13.74.10) corresponding to

$$(x_4 y_1)(x_2 y_1)(x_1 y_2)(x_3 y_4)(x_1 y_4)(x_2 y_5)$$

[622] Such a bijection will then automatically satisfy $|\lambda| = \ell$, where λ is the (common) shape of P and Q, and where ℓ is the length of the strict cobiword $\binom{\mathbf{i}}{\mathbf{j}}$. This is because $|\lambda| = |\operatorname{cont}(Q)|$ and $\ell = |\operatorname{cont}(\mathbf{i})|$.

[623] This algorithm appears in Fulton's [73, §A.4] as construction (1d).

is the strict cobiword $\binom{\mathbf{i}}{\mathbf{j}} = \binom{112445}{421312}$, and the coRSK algorithm applied to this cobiword proceeds as follows:

$$\begin{array}{rcl|rcl}
P_0 & = & \varnothing & Q_0 & = & \varnothing \\
P_1 & = & 4 & Q_1 & = & 1 \\
P_2 & = & \begin{array}{l} 2 \\ 4 \end{array} & Q_2 & = & \begin{array}{l} 1 \\ 1 \end{array} \\
P_3 & = & \begin{array}{l} 1 \\ 2 \\ 4 \end{array} & Q_3 & = & \begin{array}{l} 1 \\ 1 \\ 3 \end{array} \\
P_4 & = & \begin{array}{ll} 1 & 3 \\ 2 & \\ 4 & \end{array} & Q_4 & = & \begin{array}{ll} 1 & 4 \\ 1 & \\ 2 & \end{array} \\
P_5 & = & \begin{array}{ll} 1 & 1 \\ 2 & 3 \\ 4 & \end{array} & Q_5 & = & \begin{array}{ll} 1 & 4 \\ 1 & 4 \\ 2 & \end{array} \\
P := P_6 & = & \begin{array}{lll} 1 & 1 & 2 \\ 2 & 3 & \\ 4 & & \end{array} & Q := Q_6 & = & \begin{array}{lll} 1 & 4 & 5 \\ 1 & 4 & \\ 2 & & \end{array}
\end{array}$$

It is clear that P_m remains a column-strict tableau of some Ferrers shape throughout the execution of the coRSK algorithm, and that Q_m remains a filling of the same shape as P_m which is (at least) weakly increasing left-to-right along rows and weakly increasing top-to-bottom in columns. But we can also see that Q_m is strictly increasing left-to-right along rows[624], so that Q_m is a row-strict tableau. Thus, the result (P, Q) of the coRSK algorithm is a tableau-cotableau pair.

To see that the coRSK algorithm is a bijection, we show how to recover $\binom{\mathbf{i}}{\mathbf{j}}$ from (P, Q). This is done by reverse bumping in the same way as for the usual RSK algorithm, with the only difference that now Q_m is obtained by removing the bottommost (rather than the rightmost) occurrence of the letter i_{m+1} from Q_{m+1}.[625]

Finally, to see that the coRSK map is surjective, one needs to show that the reverse bumping procedure can be applied to any tableau-cotableau pair (P, Q), and will result in a strict cobiword $\binom{\mathbf{i}}{\mathbf{j}}$. We leave this verification to the reader.[626]

[624] Indeed, this follows from the observation that when one has a string of equal letters $i_m = i_{m+1} = \cdots = i_{m+r}$ on top of the strict cobiword, then the bottom letters bumped in are $j_m > j_{m+1} > \cdots > j_{m+r}$, and therefore (as a consequence of the last claim of part (b) of the row bumping lemma) the new cells form a *vertical strip*, that is, no two of these cells lie in the same row. Actually, more can be said: Each of these new cells (except for the first one) is in a row further down than the previous one. We will use this stronger fact further below.

[625] It necessarily has to be the bottommost occurrence, since (according to the previous footnote) the cell into which i_{m+1} was filled at the step from Q_m to Q_{m+1} lies further down than any existing cell of Q_m containing the letter i_{m+1}.

[626] It is easy to see that repeatedly applying reverse bumping to (P, Q) will result in a sequence $\binom{i_\ell}{j_\ell}, \binom{i_{\ell-1}}{j_{\ell-1}}, \ldots, \binom{i_1}{j_1}$ of biletters such that applying the coRSK algorithm to $\binom{i_1 \cdots i_\ell}{j_1 \cdots j_\ell}$ gives back (P, Q). The question is why we have $\binom{i_1}{j_1} <_{alex} \cdots <_{alex} \binom{i_\ell}{j_\ell}$. Since the chain of inequalities $i_1 \leq i_2 \leq \cdots \leq i_\ell$ is clear from the choice of entry to reverse-bump, it only remains to show that for every string $i_m = i_{m+1} = \cdots = i_{m+r}$ of equal top letters, the corresponding bottom letters strictly decrease (that is, $j_m > j_{m+1} > \cdots > j_{m+r}$). One way to see this is the following:

Assume the contrary; i.e., assume that the bottom letters corresponding to some string $i_m = i_{m+1} = \cdots = i_{m+r}$ of equal top letters do not strictly decrease. Thus, $j_{m+p} \leq j_{m+p+1}$ for some $p \in \{0, 1, \ldots, r-1\}$. Consider this p.

Let us consider the cells containing the equal letters $i_m = i_{m+1} = \cdots = i_{m+r}$ in the tableau Q_{m+r}. Label these cells as $c_m, c_{m+1}, \ldots, c_{m+r}$ from top to bottom (noticing that no two of them lie in the same row, since Q_{m+r} is row-strict). By the definition of reverse bumping, the first entry to be reverse bumped from P_{m+r} is the entry in position c_{m+r} (since this is the bottommost occurrence of the letter i_{m+r} in Q_{m+r}); then, the next entry to be reverse bumped is the one in position c_{m+r-1}, So the coRSK map is a bijection having the required properties. As we have said, this proves (13.74.11). This solves Exercise 2.7.12(a) again.

[*Remark:* By combining the two solutions of Exercise 2.7.12(a) given above, one can obtain a new proof of the equality (13.74.7) (a proof which does not use (2.4.15)). Indeed, using (2.4.12), we can rewrite (13.74.6) as

$$\sum_{\lambda\in\operatorname{Par}} \omega\left(s_\lambda\left(\mathbf{x}\right)\right) s_\lambda\left(\mathbf{y}\right) = \sum_{\lambda\in\operatorname{Par}} e_\lambda\left(\mathbf{x}\right) m_\lambda\left(\mathbf{y}\right).$$

Compared with (13.74.4), this yields

$$\begin{aligned} &\sum_{\lambda\in\operatorname{Par}} \omega\left(s_\lambda\left(\mathbf{x}\right)\right) s_\lambda\left(\mathbf{y}\right) \\ &= \prod_{i,j=1}^{\infty}\left(1+x_iy_j\right) = \prod_{i,j=1}^{\infty}\left(1+x_jy_i\right) \qquad \text{(here, we substituted } (j,i) \text{ for } (i,j) \text{ in the sum)} \\ &= \prod_{i,j=1}^{\infty}\left(1+y_ix_j\right) = \sum_{\lambda\in\operatorname{Par}} s_\lambda\left(\mathbf{y}\right) s_{\lambda^t}\left(\mathbf{x}\right) \qquad \text{(by (13.74.10), with } \mathbf{x} \text{ and } \mathbf{y} \text{ substituted for } \mathbf{y} \text{ and } \mathbf{x}\text{)} \\ &= \sum_{\lambda\in\operatorname{Par}} s_{\lambda^t}\left(\mathbf{x}\right) s_\lambda\left(\mathbf{y}\right). \end{aligned}$$

Since the $s_\lambda\left(\mathbf{y}\right)$ for $\lambda\in\operatorname{Par}$ are linearly independent over $\mathbf{k}\left[\left[\mathbf{x}\right]\right]$, we can compare coefficients before $s_\lambda\left(\mathbf{y}\right)$ in this equality. As a result, we obtain $\omega\left(s_\lambda\left(\mathbf{x}\right)\right) = s_{\lambda^t}\left(\mathbf{x}\right)$ for every $\lambda\in\operatorname{Par}$. Thus, (13.74.7) is proven again.]

Third solution to Exercise 2.7.12(a): In order to solve Exercise 2.7.12(a), it suffices to verify the identity (13.74.11). (This can be proven by the same argument as in the Second solution to Exercise 2.7.12(a).)

We shall now verify the identity (13.74.11) using the so-called *dual RSK algorithm* (also known as *RSK* algorithm*)[627]. This will be fairly similar to the Second solution to Exercise 2.7.12(a) given above, but not identical to it; in particular, the dual RSK algorithm that we will introduce below will (unlike the coRSK algorithm from the Second solution) not rely on the same row bumping operation as the usual RSK algorithm, but on a somewhat modified version of it.

For a given partition λ, let us define a *row-strict tableau* of shape λ to be an assignment T of entries in $\{1,2,3,\ldots\}$ to the cells of the Ferrers diagram for λ which is strictly increasing left-to-right in rows, and weakly increasing top-to-bottom in columns. The equality (13.74.12) holds[628]; thus, we have

$$\begin{aligned} \sum_{\substack{P \text{ is a row-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(P)} &= \sum_{\substack{Q \text{ is a row-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(Q)} = s_{\lambda^t} \qquad \text{(by (13.74.12))} \\ &= s_{\lambda^t}\left(\mathbf{x}\right). \end{aligned} \tag{13.74.16}$$

We also have

$$\sum_{\substack{Q \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(Q)} = \sum_{\substack{P \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(P)} = s_\lambda\left(\mathbf{x}\right)$$

(because this is how $s_\lambda = s_\lambda\left(\mathbf{x}\right)$ is defined) for every partition λ. Substituting $\mathbf{y}$ for $\mathbf{x}$ in this equality, we obtain

$$\sum_{\substack{Q \text{ is a column-strict} \\ \text{tableau of shape } \lambda}} \mathbf{y}^{\operatorname{cont}(Q)} = s_\lambda\left(\mathbf{y}\right). \tag{13.74.17}$$

etc., moving further and further up. Thus, for each $q\in\{0,1,\ldots,r\}$, the tableau P_{m+q-1} is obtained from P_{m+q} by reverse bumping the entry in position c_{m+q}. Hence, conversely, the tableau P_{m+q} is obtained from P_{m+q-1} by RS-inserting the entry j_{m+q}, which creates the corner cell c_{m+q}.

But recall that $j_{m+p}\leq j_{m+p+1}$. Hence, part (a) of the row bumping lemma (applied to P_{m+p-1}, j_{m+p}, j_{m+p+1}, P_{m+p}, c_{m+p}, P_{m+p+1} and c_{m+p+1} instead of P, j, j', P', c, P'' and c') shows that the cell c_{m+p+1} is in the same row as the cell c_{m+p} or in a row further up. But this contradicts the fact that the cell c_{m+p+1} is in a row further down than the cell c_{m+p} (since we have labeled our cells as $c_m, c_{m+1},\ldots,c_{m+r}$ from top to bottom, and no two of them lied in the same row). This contradiction completes our proof.

[627] We will define this algorithm further below. It also frequently appears in literature: see, e.g., [206, §7.14], [111, §5], [186, Theorem 4.8.5] and (with different conventions) [73, §A.4.3, Prop. 3].

[628] Indeed, it can be proven as in the Second solution to Exercise 2.7.12(a).

A *cotableau-tableau pair* will mean a pair (P, Q) such that P is a row-strict tableau, Q is a column-strict tableau, and P and Q both have shape λ for one and the same partition λ. Multiplying the identities (13.74.16) and (13.74.17) and multiplying the result with $t^{|\lambda|}$, we obtain

$$t^{|\lambda|} \sum_{\substack{(P,Q) \text{ is a pair with} \\ P \text{ being a row-strict tableau} \\ \text{of shape } \lambda, \text{ and } Q \text{ being} \\ \text{a column-strict tableau of shape } \lambda}} \mathbf{x}^{\operatorname{cont}(P)} \mathbf{y}^{\operatorname{cont}(Q)} = t^{|\lambda|} s_{\lambda^t} (\mathbf{x}) \, s_\lambda (\mathbf{y})$$

for every partition λ. Summing this equality over all partitions λ, we obtain

$$\sum t^{|\lambda|} \mathbf{x}^{\operatorname{cont}(P)} \mathbf{y}^{\operatorname{cont}(Q)} = \sum_{\lambda \in \operatorname{Par}} t^{|\lambda|} s_{\lambda^t} (\mathbf{x}) \, s_\lambda (\mathbf{y}) ,$$

where the sum on the left hand side is over all cotableau-tableau pairs (P, Q) and where λ denotes the common shape of P and Q. This becomes

$$\begin{aligned} \sum t^{|\lambda|} \mathbf{x}^{\operatorname{cont}(P)} \mathbf{y}^{\operatorname{cont}(Q)} &= \sum_{\lambda \in \operatorname{Par}} t^{|\lambda|} s_{\lambda^t} (\mathbf{x}) \, s_\lambda (\mathbf{y}) = \sum_{\lambda \in \operatorname{Par}} \underbrace{t^{\left|\lambda^t\right|}}_{\substack{= t^{|\lambda|} \\ (\text{since } \left|\lambda^t\right| = |\lambda|)}} \underbrace{s_{\left(\lambda^t\right)^t} (\mathbf{x})}_{\substack{= s_\lambda(\mathbf{x}) \\ (\text{since } \left(\lambda^t\right)^t = \lambda)}} s_{\lambda^t} (\mathbf{y}) \\ &\qquad \left(\begin{array}{c} \text{here, we substituted } \lambda^t \text{ for } \lambda \text{ in the sum, since the map} \\ \operatorname{Par} \to \operatorname{Par}, \ \lambda \mapsto \lambda^t \text{ is a bijection} \end{array} \right) \\ &= \sum_{\lambda \in \operatorname{Par}} t^{|\lambda|} s_\lambda (\mathbf{x}) \, s_{\lambda^t} (\mathbf{y}) . \end{aligned} \tag{13.74.18}$$

We shall use all notations introduced in the proof of Theorem 2.5.1. A *strict biword* will mean an array $\binom{\mathbf{i}}{\mathbf{j}} = \binom{i_1 \ldots i_\ell}{j_1 \ldots j_\ell}$ in which the biletters satisfy $\binom{i_1}{j_1} <_{lex} \cdots <_{lex} \binom{i_\ell}{j_\ell}$ (that is, the biletters are distinct and ordered with respect to the lexicographic order). Strict biwords are clearly in 1-to-1 correspondence with sets (not multisets!) of biletters. Now, the left hand side of (13.74.11) is $\prod_{i,j=1}^{\infty} (1 + t x_i y_j) = \prod_{i,j=1}^{\infty} (1 + t x_j y_i)$ (here, we substituted (j, i) for the index (i, j) in the product), and thus can be rewritten as the sum of $t^\ell (x_{j_1} y_{i_1}) (x_{j_2} y_{i_2}) \cdots (x_{j_\ell} y_{i_\ell})$ over all sets $\left\{ \binom{i_1}{j_1}, \ldots, \binom{i_\ell}{j_\ell} \right\}$ of biletters. Thus, the left hand side of (13.74.11) is the sum $\sum t^\ell \mathbf{x}^{\operatorname{cont}(\mathbf{j})} \mathbf{y}^{\operatorname{cont}(\mathbf{i})}$ over all strict biwords $\binom{\mathbf{i}}{\mathbf{j}}$, where ℓ stands for the number of biletters in the biword. Meanwhile, we know that the right hand side of (13.74.11) is the sum $\sum t^{|\lambda|} \mathbf{x}^{\operatorname{cont}(P)} \mathbf{y}^{\operatorname{cont}(Q)}$ over all cotableau-tableau pairs (P, Q) (because of (13.74.18)). Thus, in order to prove (13.74.11), we only need to construct a bijection between the strict biwords $\binom{\mathbf{i}}{\mathbf{j}}$ and the cotableau-tableau pairs (P, Q), which has the property that

$$\begin{aligned} \operatorname{cont}(\mathbf{i}) &= \operatorname{cont}(Q) ; \\ \operatorname{cont}(\mathbf{j}) &= \operatorname{cont}(P) . \end{aligned}$$

[629]

This bijection is the *dual RSK algorithm*, which we shall define below.

First, we shall introduce a simpler operation which we call *dual RS-insertion* (and which is similar to RS-insertion, but not identical with it[630]).

Dual RS-insertion takes as input a row-strict tableau P and a letter j, and returns a new row-strict tableau P' along with a corner cell c of P', which is constructed as follows: Start out by setting $P' = P$. The letter j tries to insert itself into the first row of P' by either bumping out the leftmost letter in the first row **larger or equal to** j, or else placing itself at the right end of the row if no such letter (larger or equal to j) exists. If a letter was bumped from the first row, this letter follows the same rules to insert itself into the second row, and so on. This series of bumps must eventually come to an end. At the end of the bumping, the tableau P' created has an extra corner cell not present in P. If we call this corner cell c, then P' (in its final form) and c are what the dual RS-insertion operation returns. One says that P' is the

[629] Such a bijection will then automatically satisfy $|\lambda| = \ell$, where λ is the (common) shape of P and Q, and where ℓ is the length of the strict biword $\binom{\mathbf{i}}{\mathbf{j}}$. This is because $|\lambda| = |\operatorname{cont}(Q)|$ and $\ell = |\operatorname{cont}(\mathbf{i})|$.

[630] We will leave many of its properties unproven, because their proofs are analogous (or at least very similar) to the proofs of the corresponding properties of RS-insertion, and thus can be easily reconstructed by the reader.

result of *dually inserting* j into the tableau P. It is straightforward to see that this resulting filling P' is a row-strict tableau[631].

Example 13.74.2. To give an example of this operation, let us dually insert the letter $j = 3$ into the row-strict tableau $\begin{array}{llll} 1 & 2 & 3 & 5 \\ 1 & 2 & 4 & \\ 3 & 4 & 7 & \\ 3 & 6 & & \\ 4 & & & \end{array}$ (we are showing all intermediate states of P'; the underlined letter is always the one that is going to be bumped out at the next step):

$$\begin{array}{llll} 1 & 2 & \underline{3} & 5 \\ 1 & 2 & 4 & \\ 3 & 4 & 7 & \\ 3 & 6 & & \\ 4 & & & \end{array} \xmapsto[\substack{\text{insert 3;}\\ \text{bump out 3}}]{} \begin{array}{llll} 1 & 2 & 3 & 5 \\ 1 & 2 & \underline{4} & \\ 3 & 4 & 7 & \\ 3 & 6 & & \\ 4 & & & \end{array} \xmapsto[\substack{\text{insert 3;}\\ \text{bump out 4}}]{} \begin{array}{llll} 1 & 2 & 3 & 5 \\ 1 & 2 & 3 & \\ 3 & \underline{4} & 7 & \\ 3 & 6 & & \\ 4 & & & \end{array}$$

$$\xmapsto[\substack{\text{insert 4;}\\ \text{bump out 4}}]{} \begin{array}{llll} 1 & 2 & 3 & 5 \\ 1 & 2 & 3 & \\ 3 & 4 & 7 & \\ 3 & \underline{6} & & \\ 4 & & & \end{array} \xmapsto[\substack{\text{insert 4;}\\ \text{bump out 6}}]{} \begin{array}{llll} 1 & 2 & 3 & 5 \\ 1 & 2 & 3 & \\ 3 & 4 & 7 & \\ 3 & 4 & & \\ 4 & & & \end{array} \xmapsto[\substack{\text{insert 6;}\\ \text{done}}]{} \begin{array}{llll} 1 & 2 & 3 & 5 \\ 1 & 2 & 3 & \\ 3 & 4 & 7 & \\ 3 & 4 & & \\ 4 & 6 & & \end{array} .$$

The last tableau in this sequence is the row-strict tableau that is returned. The corner cell that is returned is the second cell of the fifth row (the one containing 6).

Dual RS-insertion will be used as a step in the dual RSK algorithm; the construction will rely on a simple fact known as the *dual row bumping lemma*. Let us first define the notion of a *dual bumping path* (or *dual bumping route*): If P is a row-strict tableau, and j is a letter, then some letters are inserted into some cells when dual RS-insertion is applied to P and j. The sequence of these cells (in the order in which they see letters inserted into them)[632] is called the *dual bumping path* for P and j. This dual bumping path always ends with the corner cell c which is returned by dual RS-insertion. As an example, when $j = 3$ is dually inserted into the tableau P shown below, the result P' is shown with all entries on the dual bumping path underlined:

$$P = \begin{array}{llll} 1 & 2 & 3 & 4 \\ 1 & 2 & 4 & 6 \\ 2 & 4 & 5 & 6 \\ 2 & 4 & & \\ 3 & & & \end{array} \quad \xmapsto[j=3]{\text{dually insert}} \quad P' = \begin{array}{llll} 1 & 2 & \underline{3} & 4 \\ 1 & 2 & \underline{3} & 6 \\ 2 & \underline{4} & 5 & 6 \\ 2 & \underline{4} & & \\ 3 & \underline{4} & & \end{array}$$

A first simple observation about dual bumping paths is that dual bumping paths trend weakly left (just as bumping paths for regular RS-insertion do). A subtler property of bumping paths is the following *dual row bumping lemma*[633]:

> **Dual row bumping lemma:** Let P be a row-strict tableau, and let j and j' be two letters. Applying dual RS-insertion to the tableau P and the letter j yields a new row-strict tableau P' and a corner cell c. Applying dual RS-insertion to the tableau P' and the letter j' yields a new row-strict tableau P'' and a corner cell c'.
>
> (a) Assume that $j < j'$. Then, the dual bumping path for P' and j' stays strictly to the right, within each row, of the dual bumping path for P and j. The cell c' (in which the dual bumping path for P' and j' ends) is in the same row as the cell c (in which the dual bumping path for P and j ends) or in a row further up; it is also in a column further right than c.

[631] Indeed, the reader can check that P' remains a row-strict tableau throughout the algorithm that defines dual RS-insertion.

[632] In particular, this includes those cells whose entries did not change under the insertion (because the entry inserted was the same as the entry they contained before the insertion).

[633] This lemma is equivalent to the "column bumping lemma" in Fulton [73, p. 187].

(b) Assume instead that $j \geq j'$. Then, the dual bumping path for P' and j' stays weakly to the left, within each row, of the dual bumping path for P and j. The cell c' (in which the dual bumping path for P' and j' ends) is in a row further down than the cell c (in which the dual bumping path for P and j ends); it is also in the same column as c or in a column further left.

This lemma can be easily proven by induction over the row (similarly to the usual row bumping lemma).

We will now define the dual RSK algorithm. Let $\binom{\mathbf{i}}{\mathbf{j}}$ be a strict biword. Starting with the pair $(P_0, Q_0) = (\varnothing, \varnothing)$ and $m = 0$, the algorithm applies the following steps (see Example 13.74.3 below):

- If i_{m+1} does not exist (that is, m is the length of $\mathbf{i}$), stop.
- Apply dual RS-insertion to the row-strict tableau P_m and the letter j_{m+1} (the bottom letter of $\binom{i_{m+1}}{j_{m+1}}$). Let P_{m+1} be the resulting row-strict tableau, and let c_{m+1} be the resulting corner cell.
- Create Q_{m+1} from Q_m by adding the top letter i_{m+1} of $\binom{i_{m+1}}{j_{m+1}}$ to Q_m in the cell c_{m+1} (which, as we recall, is the extra corner cell of P_{m+1} not present in P_m).
- Set m to $m + 1$.

After all of the biletters have been thus processed, the result of the dual RSK algorithm is $(P_\ell, Q_\ell) =: (P, Q)$.

Example 13.74.3. The term in the expansion of the left side of (13.74.10) corresponding to

$$(x_2y_1)(x_4y_1)(x_1y_2)(x_1y_4)(x_3y_4)(x_2y_5)$$

is the strict biword $\binom{\mathbf{i}}{\mathbf{j}} = \binom{112445}{241132}$, and the dual RSK algorithm applied to this biword proceeds as follows:

$$\begin{array}{rcl|rcl}
P_0 & = & \varnothing & Q_0 & = & \varnothing \\[1em]
P_1 & = & 2 & Q_1 & = & 1 \\[1em]
P_2 & = & 2 \quad 4 & Q_2 & = & 1 \quad 1 \\[1em]
P_3 & = & \begin{array}{ll} 1 & 4 \\ 2 & \end{array} & Q_3 & = & \begin{array}{ll} 1 & 1 \\ 2 & \end{array} \\[1em]
P_4 & = & \begin{array}{ll} 1 & 4 \\ 1 & \\ 2 & \end{array} & Q_4 & = & \begin{array}{ll} 1 & 1 \\ 2 & \\ 4 & \end{array} \\[1em]
P_5 & = & \begin{array}{ll} 1 & 3 \\ 1 & 4 \\ 2 & \end{array} & Q_5 & = & \begin{array}{ll} 1 & 1 \\ 2 & 4 \\ 4 & \end{array} \\[1em]
P := P_6 & = & \begin{array}{ll} 1 & 2 \\ 1 & 3 \\ 2 & 4 \end{array} & Q := Q_6 & = & \begin{array}{ll} 1 & 1 \\ 2 & 4 \\ 4 & 5 \end{array}
\end{array}$$

It is clear that P_m remains a row-strict tableau of some Ferrers shape throughout the execution of the dual RSK algorithm, and that Q_m remains a filling of the same shape as P_m which is (at least) weakly increasing left-to-right along rows and weakly increasing top-to-bottom in columns. But we can also see that Q_m is strictly increasing top-to-bottom along columns[634], so that Q_m is a column-strict tableau. Thus, the result (P, Q) of the dual RSK algorithm is a cotableau-tableau pair.

[634] Indeed, this follows from the observation that when one has a string of equal letters $i_m = i_{m+1} = \cdots = i_{m+r}$ on top of the strict biword, then the bottom letters bumped in are $j_m < j_{m+1} < \cdots < j_{m+r}$, and therefore (as a consequence of the second-to-last claim of part (a) of the dual row bumping lemma) the new cells form a *horizontal strip*, that is, no two of these cells lie in the same column. Actually, more can be said: Each of these new cells (except for the first one) is in a column further right than the previous one. We will use this stronger fact further below.

To see that the dual RSK algorithm is a bijection, we show how to recover $\binom{\mathbf{i}}{\mathbf{j}}$ from (P, Q). This is done by *dually reverse bumping* from (P_{m+1}, Q_{m+1}) to recover both the biletter $\binom{i_{m+1}}{j_{m+1}}$ and the tableaux (P_m, Q_m), as follows. Firstly, i_{m+1} is the maximum entry of Q_{m+1}, and Q_m is obtained by removing the rightmost occurrence of this letter i_{m+1} from Q_{m+1}. [635] To produce P_m and j_{m+1}, find the position of the rightmost occurrence of i_{m+1} in Q_{m+1}, and start *dually reverse bumping* in P_{m+1} from the entry in this same position, where dually reverse bumping an entry means inserting it into one row higher by having it bump out the rightmost entry which is smaller or equal to it.[636] The entry bumped out of the first row is j_{m+1}, and the resulting tableau is P_m.

Finally, to see that the dual RSK map is surjective, one needs to show that the dually reverse bumping procedure can be applied to any cotableau-tableau pair (P, Q), and will result in a strict biword $\binom{\mathbf{i}}{\mathbf{j}}$. We leave this verification to the reader.[637]

So the dual RSK map is a bijection having the required properties. As we have said, this proves (13.74.11). This solves Exercise 2.7.12(a) again.

(b) Let us consider the map $\omega\left[\left[\mathbf{y}\right]\right] : \Lambda\left[\left[\mathbf{y}\right]\right] \to \Lambda\left[\left[\mathbf{y}\right]\right]$ defined as in the solution of Exercise 2.7.12(a).

Now, the equality (2.5.1) yields

$$\sum_{\lambda\in\operatorname{Par}} s_\lambda\left(\mathbf{x}\right) s_\lambda\left(\mathbf{y}\right) = \prod_{i,j=1}^{\infty} \left(1 - x_i y_j\right)^{-1} = \sum_{\lambda\in\operatorname{Par}} z_\lambda^{-1} p_\lambda\left(\mathbf{x}\right) p_\lambda\left(\mathbf{y}\right) \qquad \left(\text{by } (2.5.11)\right). \tag{13.74.19}$$

This is an equality in $\Lambda\left[\left[\mathbf{y}\right]\right]$ (because $s_\lambda\left(\mathbf{x}\right)$ and $p_\lambda\left(\mathbf{x}\right)$ belong to Λ for every $\lambda \in \operatorname{Par}$). Hence, we can apply the map $\omega\left[\left[\mathbf{y}\right]\right] : \Lambda\left[\left[\mathbf{y}\right]\right] \to \Lambda\left[\left[\mathbf{y}\right]\right]$ to both sides of this equality. As a result, we obtain

$$\sum_{\lambda\in\operatorname{Par}} \omega\left(s_\lambda\left(\mathbf{x}\right)\right) s_\lambda\left(\mathbf{y}\right) = \sum_{\lambda\in\operatorname{Par}} z_\lambda^{-1} \omega\left(p_\lambda\left(\mathbf{x}\right)\right) p_\lambda\left(\mathbf{y}\right)$$

(because $\omega\left[\left[\mathbf{y}\right]\right]$, being a $\mathbf{k}\left[\left[\mathbf{y}\right]\right]$-algebra homomorphism, leaves the $s_\lambda\left(\mathbf{y}\right)$ and $p_\lambda\left(\mathbf{y}\right)$ terms unchanged, while the $s_\lambda\left(\mathbf{x}\right)$ and $p_\lambda\left(\mathbf{x}\right)$ terms are elements of Λ and thus are transformed as by ω). Due to (2.4.14) and

[635] It necessarily has to be the rightmost occurrence, since (according to the previous footnote) the cell into which i_{m+1} was filled at the step from Q_m to Q_{m+1} lies further right than any existing cell of Q_m containing the letter i_{m+1}.

[636] Let us give a few more details on this "dually reverse bumping" procedure. Dually reverse bumping (also known as *dual RS-deletion* or *reverse dual RS-insertion*) is an operation which takes a row-strict tableau P' and a corner cell c of P', and constructs a row-strict tableau P and a letter j such that dual RS-insertion for P and j yields P' and c. It starts by setting $P = P'$, and removing the entry in the cell c from P. This removed entry is then denoted by k, and is inserted into the row of P above c, bumping out the rightmost entry which is smaller or equal to k. The letter which is bumped out – say, ℓ –, in turn, is inserted into the row above it, bumping out the rightmost entry which is smaller or equal to ℓ. This procedure continues in the same way until an entry is bumped out of the first row (which will eventually happen). The dually reverse bumping operation returns the resulting tableau P and the entry which is bumped out of the first row.

It is straightforward to check that the dually reverse bumping operation is well-defined (i.e., P does stay a row-strict tableau throughout the procedure) and is the inverse of the dual RS-insertion operation. (In fact, these two operations undo each other step by step.)

[637] It is easy to see that repeatedly applying dually reverse bumping to (P, Q) will result in a sequence $\binom{i_\ell}{j_\ell}, \binom{i_{\ell-1}}{j_{\ell-1}}, \ldots, \binom{i_1}{j_1}$ of biletters such that applying the dual RSK algorithm to $\binom{i_1 \cdots i_\ell}{j_1 \cdots j_\ell}$ gives back (P, Q). The question is why we have $\binom{i_1}{j_1} <_{lex} \cdots <_{lex} \binom{i_\ell}{j_\ell}$. Since the chain of inequalities $i_1 \leq i_2 \leq \cdots \leq i_\ell$ is clear from the choice of entry to dually reverse-bump, it only remains to show that for every string $i_m = i_{m+1} = \cdots = i_{m+r}$ of equal top letters, the corresponding bottom letters strictly increase (that is, $j_m < j_{m+1} < \cdots < j_{m+r}$). One way to see this is the following:

Assume the contrary; i.e., assume that the bottom letters corresponding to some string $i_m = i_{m+1} = \cdots = i_{m+r}$ of equal top letters do not strictly increase. Thus, $j_{m+p} \geq j_{m+p+1}$ for some $p \in \{0, 1, \ldots, r-1\}$. Consider this p.

Let us consider the cells containing the equal letters $i_m = i_{m+1} = \cdots = i_{m+r}$ in the tableau Q_{m+r}. Label these cells as $c_m, c_{m+1}, \ldots, c_{m+r}$ from left to right (noticing that no two of them lie in the same column, since Q_{m+r} is column-strict). By the definition of dually reverse bumping, the first entry to be dually reverse bumped from P_{m+r} is the entry in position c_{m+r} (since this is the rightmost occurrence of the letter i_{m+r} in Q_{m+r}); then, the next entry to be dually reverse bumped is the one in position c_{m+r-1}, etc., moving further and further left. Thus, for each $q \in \{0, 1, \ldots, r\}$, the tableau P_{m+q-1} is obtained from P_{m+q} by dually reverse bumping the entry in position c_{m+q}. Hence, conversely, the tableau P_{m+q} is obtained from P_{m+q-1} by dually RS-inserting the entry j_{m+q}, which creates the corner cell c_{m+q}.

But recall that $j_{m+p} \geq j_{m+p+1}$. Hence, part (b) of the dual row bumping lemma (applied to P_{m+p-1}, j_{m+p}, j_{m+p+1}, P_{m+p}, c_{m+p}, P_{m+p+1} and c_{m+p+1} instead of P, j, j', P', c, P'' and c') shows that the cell c_{m+p+1} is in the same column as the cell c_{m+p} or in a column further left. But this contradicts the fact that the cell c_{m+p+1} is in a column further right than the cell c_{m+p} (since we have labeled our cells as $c_m, c_{m+1}, \ldots, c_{m+r}$ from left to right, and no two of them lied in the same column). This contradiction completes our proof.

(13.74.7), this rewrites as

$$\sum_{\lambda\in\operatorname{Par}} s_{\lambda^t}\left(\mathbf{x}\right) s_\lambda\left(\mathbf{y}\right) = \sum_{\lambda\in\operatorname{Par}} z_\lambda^{-1}\left(-1\right)^{\left|\lambda\right|-\ell\left(\lambda\right)} p_\lambda\left(\mathbf{x}\right) p_\lambda\left(\mathbf{y}\right).$$

Since $\sum_{\lambda\in\operatorname{Par}} s_{\lambda^t}\left(\mathbf{x}\right) s_\lambda\left(\mathbf{y}\right) = \sum_{\lambda\in\operatorname{Par}} s_\lambda\left(\mathbf{x}\right) s_{\lambda^t}\left(\mathbf{y}\right)$ (this can be proven just as in (13.74.8)), this rewrites as

$$\sum_{\lambda\in\operatorname{Par}} s_\lambda\left(\mathbf{x}\right) s_{\lambda^t}\left(\mathbf{y}\right) = \sum_{\lambda\in\operatorname{Par}} z_\lambda^{-1}\left(-1\right)^{\left|\lambda\right|-\ell\left(\lambda\right)} p_\lambda\left(\mathbf{x}\right) p_\lambda\left(\mathbf{y}\right) = \sum_{\lambda\in\operatorname{Par}} \left(-1\right)^{\left|\lambda\right|-\ell\left(\lambda\right)} z_\lambda^{-1} p_\lambda\left(\mathbf{x}\right) p_\lambda\left(\mathbf{y}\right).$$

Hence,

$$\sum_{\lambda\in\operatorname{Par}} \left(-1\right)^{\left|\lambda\right|-\ell\left(\lambda\right)} z_\lambda^{-1} p_\lambda\left(\mathbf{x}\right) p_\lambda\left(\mathbf{y}\right) = \sum_{\lambda\in\operatorname{Par}} s_\lambda\left(\mathbf{x}\right) s_{\lambda^t}\left(\mathbf{y}\right) = \prod_{i,j=1}^{\infty}\left(1+x_iy_j\right)$$

(by (13.74.9)). This solves Exercise 2.7.12(b).

13.75. **Solution to Exercise 2.7.13.** *Solution to Exercise 2.7.13. Proof of Theorem 2.4.6.*

Let $n\in\mathbb{N}$. Let μ be a partition having at most n parts. Exercise 2.5.11(a) yields

$$\sum_{\lambda\in\operatorname{Par}} s_\lambda\left(\mathbf{x}\right) s_{\lambda/\mu}\left(\mathbf{y}\right) = s_\mu\left(\mathbf{x}\right)\cdot\prod_{i,j=1}^{\infty}\left(1-x_iy_j\right)^{-1}$$

in the ring $\mathbf{k}\left[\left[\mathbf{x},\mathbf{y}\right]\right] = \mathbf{k}\left[\left[x_1,x_2,x_3,...,y_1,y_2,y_3,...\right]\right]$. Switching the roles of the variables $\mathbf{x}$ and $\mathbf{y}$ in this equality, we obtain

$$\sum_{\lambda\in\operatorname{Par}} s_\lambda\left(\mathbf{y}\right) s_{\lambda/\mu}\left(\mathbf{x}\right) = s_\mu\left(\mathbf{y}\right)\cdot\prod_{i,j=1}^{\infty}\left(1-y_ix_j\right)^{-1}.$$

We can now substitute $\left(y_1,y_2,...,y_n,0,0,0,...\right)$ for $\left(y_1,y_2,y_3,...\right)$ on both sides of this, and obtain the equality

$$\sum_{\lambda\in\operatorname{Par}} s_\lambda\left(y_1,y_2,...,y_n\right) s_{\lambda/\mu}\left(\mathbf{x}\right) = s_\mu\left(y_1,y_2,...,y_n\right)\cdot\prod_{i=1}^{n}\prod_{j=1}^{\infty}\left(1-y_ix_j\right)^{-1}$$

in the subring $\left(\mathbf{k}\left[\left[\mathbf{x}\right]\right]\right)\left[\left[y_1,y_2,...,y_n\right]\right]$ of $\mathbf{k}\left[\left[\mathbf{x},\mathbf{y}\right]\right]$ (notice that the $\prod_{i,j=1}^{\infty}\left(1-y_ix_j\right)^{-1}$ on the right hand side became $\prod_{i=1}^{n}\prod_{j=1}^{\infty}\left(1-y_ix_j\right)^{-1}$ because all factors $1-y_ix_j$ with $i>n$ got sent to $1-0x_j=1$). In the sum on the left hand side of this equality, all addends corresponding to partitions λ having more than n parts are 0 (because Exercise 2.3.8(b) yields that all such λ satisfy $s_\lambda\left(x_1,x_2,\ldots,x_n\right)=0$, hence $s_\lambda\left(y_1,y_2,...,y_n\right)=0$). Thus, we can remove all these addends, and the equality thus becomes

$$\sum_{\substack{\lambda\in\operatorname{Par};\\ \lambda\text{ has at most }n\text{ parts}}} s_\lambda\left(y_1,y_2,...,y_n\right) s_{\lambda/\mu}\left(\mathbf{x}\right) = s_\mu\left(y_1,y_2,...,y_n\right)\cdot\prod_{i=1}^{n}\prod_{j=1}^{\infty}\left(1-y_ix_j\right)^{-1}. \tag{13.75.1}$$

Let ρ be the n-tuple $\left(n-1,n-2,...,2,1,0\right)\in\mathbb{N}^n$. We can regard ρ as a weak composition by padding it with zeroes at the end (i.e., identifying ρ with the weak composition $\left(n-1,n-2,...,2,1,0,0,0,0,...\right)$).

For every n-tuple $\alpha=\left(\alpha_1,\alpha_2,\ldots,\alpha_n\right)\in\mathbb{N}^n$, we define the alternant $a_\alpha\in\mathbf{k}\left[x_1,x_2,\ldots,x_n\right]$ as in Definition 2.6.2. (But other than this, we are not adapting the notations of Section 2.6.)

Now, Corollary 2.6.7 states that $s_\lambda\left(x_1,x_2,...,x_n\right) = \dfrac{a_{\lambda+\rho}}{a_\rho}$ in $\mathbf{k}\left[x_1,x_2,...,x_n\right]$ whenever λ is a partition having at most n parts. Applied to the variables $y_1,y_2,...,y_n$ instead of $x_1,x_2,...,x_n$, this yields that $s_\lambda\left(y_1,y_2,...,y_n\right) = \dfrac{a_{\lambda+\rho}\left(y_1,y_2,...,y_n\right)}{a_\rho\left(y_1,y_2,...,y_n\right)}$ whenever λ is a partition having at most n parts. This equality, applied to $\lambda=\mu$, yields $s_\mu\left(y_1,y_2,...,y_n\right) = \dfrac{a_{\mu+\rho}\left(y_1,y_2,...,y_n\right)}{a_\rho\left(y_1,y_2,...,y_n\right)}$. Substituting the last two equalities into (13.75.1), we obtain

$$\sum_{\substack{\lambda\in\operatorname{Par};\\ \lambda\text{ has at most }n\text{ parts}}} \frac{a_{\lambda+\rho}\left(y_1,y_2,...,y_n\right)}{a_\rho\left(y_1,y_2,...,y_n\right)} s_{\lambda/\mu}\left(\mathbf{x}\right) = \frac{a_{\mu+\rho}\left(y_1,y_2,...,y_n\right)}{a_\rho\left(y_1,y_2,...,y_n\right)}\cdot\prod_{i=1}^{n}\prod_{j=1}^{\infty}\left(1-y_ix_j\right)^{-1}.$$

Multiplied with $a_\rho(y_1, y_2, ..., y_n)$, this becomes

$$\sum_{\substack{\lambda \in \operatorname{Par}; \\ \lambda \text{ has at most } n \text{ parts}}} a_{\lambda+\rho}(y_1, y_2, ..., y_n) s_{\lambda/\mu}(\mathbf{x}) = a_{\mu+\rho}(y_1, y_2, ..., y_n) \cdot \prod_{i=1}^{n} \prod_{j=1}^{\infty} (1 - y_i x_j)^{-1}.$$

Renaming λ as ν on the left hand side of this equality, we obtain

$$\sum_{\substack{\nu \in \operatorname{Par}; \\ \nu \text{ has at most } n \text{ parts}}} a_{\nu+\rho}(y_1, y_2, ..., y_n) s_{\nu/\mu}(\mathbf{x}) = a_{\mu+\rho}(y_1, y_2, ..., y_n) \cdot \prod_{i=1}^{n} \prod_{j=1}^{\infty} (1 - y_i x_j)^{-1}. \tag{13.75.2}$$

Now, let λ be a partition having at most n parts. We want to find the coefficient of $y_1^{\lambda_1+n-1} y_2^{\lambda_2+n-2} ... y_n^{\lambda_n+n-n}$ on the left and the right hand sides of (13.75.2). Here, we regard (13.75.2) as an equality in the ring $(\mathbf{k}[[\mathbf{x}]])[[y_1, y_2, ..., y_n]]$, so that we consider the variables $x_1, x_2, x_3, ...$ as constants, and thus (for example) the coefficient of y_1 in $(1 + x_1)(1 + y_1)$ is $1 + x_1$ rather than 1.

We first notice that

$$\prod_{i=1}^{n} \prod_{j=1}^{\infty} (1 - y_i x_j)^{-1} = \sum_{(q_1, q_2, ..., q_n) \in \mathbb{N}^n} \left(\prod_{j=1}^{n} h_{q_j}(\mathbf{x}) \right) \cdot \left(\prod_{j=1}^{n} y_j^{q_j} \right) \tag{13.75.3}$$

[638].

Let us recall a basic fact from linear algebra, namely the explicit formula for the determinant of a matrix as a sum over permutations: Any matrix $(\alpha_{i,j})_{i,j=1,2,...,\ell}$ over a commutative ring satisfies

$$\det\left((\alpha_{i,j})_{i,j=1,2,...,\ell} \right) = \sum_{\sigma \in \mathfrak{S}_\ell} (-1)^\sigma \prod_{i=1}^{\ell} \alpha_{i,\sigma(i)}. \tag{13.75.5}$$

Applying this to $\ell = n$ and $\alpha_{i,j} = y_i^{(\mu+\rho)_j}$, we obtain

$$\det\left(\left(y_i^{(\mu+\rho)_j} \right)_{i,j=1,2,...,n} \right) = \sum_{\sigma \in \mathfrak{S}_n} (-1)^\sigma \prod_{i=1}^{n} y_i^{(\mu+\rho)_{\sigma(i)}} = \sum_{\sigma \in \mathfrak{S}_n} (-1)^\sigma \prod_{j=1}^{n} y_j^{(\mu+\rho)_{\sigma(j)}} \tag{13.75.6}$$

[638] *Proof:* The equality (2.2.18) (with the indices i and n renamed as j and q) yields

$$\prod_{j=1}^{\infty} (1 - x_j t)^{-1} = 1 + h_1(\mathbf{x}) t + h_2(\mathbf{x}) t^2 + ... = \sum_{q \geq 0} h_q(\mathbf{x}) t^q \qquad \text{in } (\mathbf{k}[[\mathbf{x}]])[[t]]. \tag{13.75.4}$$

For every $i \in \{1, 2, ..., n\}$, we have

$$\prod_{j=1}^{\infty} (1 - y_i x_j)^{-1} = \sum_{q \geq 0} h_q(\mathbf{x}) y_i^q$$

(this follows by substituting y_i for t on both sides of (13.75.4)). Thus,

$$\begin{aligned} \prod_{i=1}^{n} \underbrace{\prod_{j=1}^{\infty} (1 - y_i x_j)^{-1}}_{= \sum_{q \geq 0} h_q(\mathbf{x}) y_i^q} &= \prod_{i=1}^{n} \sum_{q \geq 0} h_q(\mathbf{x}) y_i^q = \prod_{j=1}^{n} \sum_{q \geq 0} h_q(\mathbf{x}) y_j^q \\ &= \sum_{(q_1, q_2, ..., q_n) \in \mathbb{N}^n} \underbrace{\prod_{j=1}^{n} \left(h_{q_j}(\mathbf{x}) \cdot y_j^{q_j} \right)}_{= \left(\prod_{j=1}^{n} h_{q_j}(\mathbf{x}) \right) \cdot \left(\prod_{j=1}^{n} y_j^{q_j} \right)} \qquad \text{(by the product rule)} \\ &= \sum_{(q_1, q_2, ..., q_n) \in \mathbb{N}^n} \left(\prod_{j=1}^{n} h_{q_j}(\mathbf{x}) \right) \cdot \left(\prod_{j=1}^{n} y_j^{q_j} \right), \end{aligned}$$

qed.

(here, we renamed the index i as j in the product). Now, the right hand side of (13.75.2) becomes

$$\begin{aligned}
&\underbrace{a_{\mu+\rho}\left(y_1,y_2,\ldots,y_n\right)}_{\substack{=\det\left(\left(y_i^{(\mu+\rho)_j}\right)_{i,j=1,2,\ldots,n}\right) \\ \text{(by the definition of the alternant } a_{\mu+\rho}\text{)}}} \cdot \underbrace{\prod_{i=1}^{n}\prod_{j=1}^{\infty}\left(1-y_ix_j\right)^{-1}}_{\substack{=\sum_{(q_1,q_2,\ldots,q_n)\in\mathbb{N}^n}\left(\prod_{j=1}^{n}h_{q_j}(\mathbf{x})\right)\cdot\left(\prod_{j=1}^{n}y_j^{q_j}\right) \\ \text{(by (13.75.3))}}} \\
&= \underbrace{\det\left(\left(y_i^{(\mu+\rho)_j}\right)_{i,j=1,2,\ldots,n}\right)}_{\substack{=\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma\prod_{j=1}^{n}y_j^{(\mu+\rho)_{\sigma(j)}} \\ \text{(by (13.75.6))}}} \cdot \sum_{(q_1,q_2,\ldots,q_n)\in\mathbb{N}^n}\left(\prod_{j=1}^{n}h_{q_j}(\mathbf{x})\right)\cdot\left(\prod_{j=1}^{n}y_j^{q_j}\right) \\
&= \left(\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma\prod_{j=1}^{n}y_j^{(\mu+\rho)_{\sigma(j)}}\right) \cdot \sum_{(q_1,q_2,\ldots,q_n)\in\mathbb{N}^n}\left(\prod_{j=1}^{n}h_{q_j}(\mathbf{x})\right)\cdot\left(\prod_{j=1}^{n}y_j^{q_j}\right) \\
&= \sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma\sum_{(q_1,q_2,\ldots,q_n)\in\mathbb{N}^n}\left(\prod_{j=1}^{n}h_{q_j}(\mathbf{x})\right)\cdot\underbrace{\left(\prod_{j=1}^{n}y_j^{q_j}\right)\left(\prod_{j=1}^{n}y_j^{(\mu+\rho)_{\sigma(j)}}\right)}_{=\prod_{j=1}^{n}\left(y_j^{q_j}y_j^{(\mu+\rho)_{\sigma(j)}}\right)=\prod_{j=1}^{n}y_j^{q_j+(\mu+\rho)_{\sigma(j)}}} \\
&= \sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma\sum_{(q_1,q_2,\ldots,q_n)\in\mathbb{N}^n}\left(\prod_{j=1}^{n}h_{q_j}(\mathbf{x})\right)\cdot\left(\prod_{j=1}^{n}y_j^{q_j+(\mu+\rho)_{\sigma(j)}}\right).
\end{aligned}$$

Hence, the coefficient of $y_1^{\lambda_1+n-1}y_2^{\lambda_2+n-2}\ldots y_n^{\lambda_n+n-n}$ on the right hand side of (13.75.2) equals

$$\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma\sum_{\substack{(q_1,q_2,\ldots,q_n)\in\mathbb{N}^n; \\ q_j+(\mu+\rho)_{\sigma(j)}=\lambda_j+n-j\text{ for every }j\in\{1,2,\ldots,n\}}}\prod_{j=1}^{n}h_{q_j}(\mathbf{x}). \tag{13.75.7}$$

However, for every $\sigma\in\mathfrak{S}_n$, it is easy to see that

$$\sum_{\substack{(q_1,q_2,\ldots,q_n)\in\mathbb{N}^n; \\ q_j+(\mu+\rho)_{\sigma(j)}=\lambda_j+n-j\text{ for every }j\in\{1,2,\ldots,n\}}}\prod_{j=1}^{n}h_{q_j}(\mathbf{x})=\prod_{j=1}^{n}h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}}(\mathbf{x}). \tag{13.75.8}$$

[639] Hence, the coefficient of $y_1^{\lambda_1+n-1} y_2^{\lambda_2+n-2} ... y_n^{\lambda_n+n-n}$ on the right hand side of (13.75.2) equals

$$\begin{aligned}
& \sum_{\sigma\in\mathfrak{S}_n} (-1)^\sigma \underbrace{\sum_{\substack{(q_1,q_2,...,q_n)\in\mathbb{N}^n;\\ q_j+(\mu+\rho)_{\sigma(j)}=\lambda_j+n-j \text{ for every } j\in\{1,2,...,n\}}} \prod_{j=1}^n h_{q_j}(\mathbf{x})}_{\substack{=\prod_{j=1}^n h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}}(\mathbf{x}) \\ \text{(by (13.75.8))}}} \qquad \text{(by (13.75.7))} \\
&= \sum_{\sigma\in\mathfrak{S}_n} (-1)^\sigma \prod_{j=1}^n \underbrace{h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}}}_{\substack{=h_{\lambda_j-\mu_{\sigma(j)}-j+\sigma(j)} \\ \text{(since it is easy to see that} \\ \lambda_j+n-j-(\mu+\rho)_{\sigma(j)}=\lambda_j-\mu_{\sigma(j)}-j+\sigma(j))}} (\mathbf{x}) \\
&= \sum_{\sigma\in\mathfrak{S}_n} (-1)^\sigma \prod_{j=1}^n h_{\lambda_j-\mu_{\sigma(j)}-j+\sigma(j)}(\mathbf{x}) \\
&= \sum_{\sigma\in\mathfrak{S}_n} (-1)^\sigma \prod_{i=1}^n h_{\lambda_i-\mu_{\sigma(i)}-i+\sigma(i)}(\mathbf{x}) = \det\left(\left(h_{\lambda_i-\mu_j-i+j}(\mathbf{x})\right)_{i,j=1,2,...,n}\right) \qquad (13.75.11)
\end{aligned}$$

(because applying (13.75.5) to $\ell = n$ and $\alpha_{i,j} = h_{\lambda_i-\mu_j-i+j}(\mathbf{x})$ yields $\det\left(\left(h_{\lambda_i-\mu_j-i+j}(\mathbf{x})\right)_{i,j=1,2,...,n}\right) = \sum_{\sigma\in\mathfrak{S}_n} (-1)^\sigma \prod_{i=1}^n h_{\lambda_i-\mu_{\sigma(i)}-i+\sigma(i)}(\mathbf{x})$).

On the other hand, let us study the left hand side of (13.75.2). Every partition ν having at most n parts satisfies

$$\begin{aligned}
a_{\nu+\rho}(y_1,y_2,...,y_n) &= \det\left(\left(y_i^{(\nu+\rho)_j}\right)_{i,j=1,2,...,n}\right) \qquad \text{(by the definition of the alternant } a_{\nu+\rho}\text{)} \\
&= \sum_{\sigma\in\mathfrak{S}_n} (-1)^\sigma \prod_{i=1}^n y_i^{(\nu+\rho)_{\sigma(i)}} \qquad \left(\text{by (13.75.5), applied to } \ell = n \text{ and } \alpha_{i,j} = y_i^{(\nu+\rho)_j}\right).
\end{aligned}$$

[639] *Proof.* Let $\sigma \in \mathfrak{S}_n$. It is clear that the sum

$$\sum_{\substack{(q_1,q_2,...,q_n)\in\mathbb{N}^n;\\ q_j+(\mu+\rho)_{\sigma(j)}=\lambda_j+n-j \text{ for every } j\in\{1,2,...,n\}}} \prod_{j=1}^n h_{q_j}(\mathbf{x}) \qquad (13.75.9)$$

has at most one addend: namely, the one corresponding to the n-tuple $(q_1,q_2,...,q_n) \in \mathbb{Z}^n$ defined by

$$q_j = \lambda_j + n - j - (\mu+\rho)_{\sigma(j)} \quad \text{for every } j \in \{1,2,...,n\}. \qquad (13.75.10)$$

If this n-tuple $(q_1,q_2,...,q_n)$ belongs to $\mathbb{N}^n$, then the sum (13.75.9) does have this summand. Thus, if the n-tuple $(q_1,q_2,...,q_n)$ belongs to $\mathbb{N}^n$, we have

$$\sum_{\substack{(q_1,q_2,...,q_n)\in\mathbb{N}^n;\\ q_j+(\mu+\rho)_{\sigma(j)}=\lambda_j+n-j \text{ for every } j\in\{1,2,...,n\}}} \prod_{j=1}^n h_{q_j}(\mathbf{x}) = \prod_{j=1}^n h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}}(\mathbf{x}).$$

Thus, if the n-tuple $(q_1,q_2,...,q_n)$ defined by (13.75.10) belongs to $\mathbb{N}^n$, the equality (13.75.8) is proven. It remains to consider the case when the n-tuple $(q_1,q_2,...,q_n)$ defined by (13.75.10) does not belong to $\mathbb{N}^n$. In this case, the sum (13.75.9) is empty (because the only addend it can have corresponds to the n-tuple $(q_1,q_2,...,q_n)$ defined by (13.75.10), but this n-tuple does not belong to $\mathbb{N}^n$ and therefore does not appear in the sum), hence equals 0. But since the n-tuple $(q_1,q_2,...,q_n)$ defined by (13.75.10) does not belong to $\mathbb{N}^n$, there must be a $j \in \{1,2,...,n\}$ satisfying $\lambda_j + n - j - (\mu+\rho)_{\sigma(j)} \notin \mathbb{N}$. For this j, we have $h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}} = 0$. Hence, the product $\prod_{j=1}^n h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}}(\mathbf{x})$ has a factor equal to 0; consequently, the product $\prod_{j=1}^n h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}}(\mathbf{x})$ must be 0. Thus, both the sum (13.75.9) and the product $\prod_{j=1}^n h_{\lambda_j+n-j-(\mu+\rho)_{\sigma(j)}}(\mathbf{x})$ are 0, and thus (13.75.8) is proven.

Hence, the left hand side of (13.75.2) is

$$\begin{aligned}
&\sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts}}} \underbrace{a_{\nu+\rho}\left(y_1,y_2,...,y_n\right)}_{=\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma\prod_{i=1}^n y_i^{(\nu+\rho)_{\sigma(i)}}} s_{\nu/\mu}\left(\mathbf{x}\right)\\
&=\sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts}}} \left(\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma\prod_{i=1}^n y_i^{(\nu+\rho)_{\sigma(i)}}\right) s_{\nu/\mu}\left(\mathbf{x}\right)\\
&=\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma \sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts}}} \left(\prod_{i=1}^n y_i^{(\nu+\rho)_{\sigma(i)}}\right) s_{\nu/\mu}\left(\mathbf{x}\right).
\end{aligned}$$

Thus, the coefficient of $y_1^{\lambda_1+n-1}y_2^{\lambda_2+n-2}...y_n^{\lambda_n+n-n}$ on the left hand side of (13.75.2) equals

$$\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma \sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts};\\ (\nu+\rho)_{\sigma(j)}=\lambda_j+n-j\text{ for every }j\in\{1,2,...,n\}}} s_{\nu/\mu}\left(\mathbf{x}\right). \tag{13.75.12}$$

Now let us simplify this. First, we claim that every permutation $\sigma\in\mathfrak{S}_n$ satisfying $\sigma\neq\operatorname{id}$ satisfies

$$\sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts};\\ (\nu+\rho)_{\sigma(j)}=\lambda_j+n-j\text{ for every }j\in\{1,2,...,n\}}} s_{\nu/\mu}\left(\mathbf{x}\right)=0. \tag{13.75.13}$$

[640] Thus, in the outer sum in (13.75.12), all addends which correspond to permutations $\sigma\in\mathfrak{S}_n$ satisfying $\sigma\neq\operatorname{id}$ are 0. We can therefore remove all these addends, leaving only the addend corresponding to $\sigma=\operatorname{id}$. Thus, the sum simplifies as follows:

$$\begin{aligned}
&\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma \sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts};\\ (\nu+\rho)_{\sigma(j)}=\lambda_j+n-j\text{ for every }j\in\{1,2,...,n\}}} s_{\nu/\mu}\left(\mathbf{x}\right)=\underbrace{(-1)^{\operatorname{id}}}_{=1}\underbrace{\sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts};\\ (\nu+\rho)_{\operatorname{id}(j)}=\lambda_j+n-j\text{ for every }j\in\{1,2,...,n\}}}}_{\substack{=\sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts};\\ \nu_j+n-j=\lambda_j+n-j\text{ for every }j\in\{1,2,...,n\}}}\\ (\text{since }(\nu+\rho)_{\operatorname{id}(j)}=(\nu+\rho)_j=\nu_j+n-j\text{ for all }j)}} s_{\nu/\mu}\left(\mathbf{x}\right)\\
&=\sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts};\\ \nu_j+n-j=\lambda_j+n-j\text{ for every }j\in\{1,2,...,n\}}} s_{\nu/\mu}\left(\mathbf{x}\right)=s_{\lambda/\mu}\left(\mathbf{x}\right)
\end{aligned}$$

(because there is only one $\nu\in\operatorname{Par}$ such that ν has at most n parts and satisfies $\nu_j+n-j=\lambda_j+n-j$ for every $j\in\{1,2,...,n\}$; namely, this ν is λ). Hence, the coefficient of $y_1^{\lambda_1+n-1}y_2^{\lambda_2+n-2}...y_n^{\lambda_n+n-n}$ on the left

[640] *Proof of (13.75.13):* Let $\sigma\in\mathfrak{S}_n$ be a permutation satisfying $\sigma\neq\operatorname{id}$. We need to prove (13.75.13). Of course, it is enough to show that the sum on the left hand side of (13.75.13) is empty, i.e., that there exists no $\nu\in\operatorname{Par}$ such that ν has at most n parts and satisfies $(\nu+\rho)_{\sigma(j)}=\lambda_j+n-j$ for every $j\in\{1,2,...,n\}$. Assume the contrary. Then, there exists a $\nu\in\operatorname{Par}$ such that ν has at most n parts and satisfies $(\nu+\rho)_{\sigma(j)}=\lambda_j+n-j$ for every $j\in\{1,2,...,n\}$. Consider this ν. Since ν is a partition, $\nu+\rho$ is a strict partition, i.e., we have $(\nu+\rho)_1>(\nu+\rho)_2>...>(\nu+\rho)_n$. In other words, the entries of the n-tuple $\nu+\rho$ are in strictly decreasing order. Since $\sigma\neq\operatorname{id}$, the permutation σ must mess up the order of the entries of $\nu+\rho$; thus, we **cannot have** $(\nu+\rho)_{\sigma(1)}>(\nu+\rho)_{\sigma(2)}>...>(\nu+\rho)_{\sigma(n)}$. Since $(\nu+\rho)_{\sigma(j)}=\lambda_j+n-j$ for every $j\in\{1,2,...,n\}$, this rewrites as follows: We **cannot** have $\lambda_1+n-1>\lambda_2+n-2>...>\lambda_n+n-n$.

But since λ is a partition, we have $\lambda_1\geq\lambda_2\geq...\geq\lambda_n$, thus $\lambda_1+n-1>\lambda_2+n-2>...>\lambda_n+n-n$. This contradicts the fact that we cannot have $\lambda_1+n-1>\lambda_2+n-2>...>\lambda_n+n-n$. This contradiction finishes the proof.

hand side of (13.75.2) equals

$$\sum_{\sigma\in\mathfrak{S}_n}(-1)^\sigma \sum_{\substack{\nu\in\operatorname{Par};\\ \nu\text{ has at most }n\text{ parts;}\\ (\nu+\rho)_{\sigma(j)}=\lambda_j+n-j\text{ for every }j\in\{1,2,\ldots,n\}}} s_{\nu/\mu}(\mathbf{x}) \qquad (\text{by (13.75.12)})$$

$$= s_{\lambda/\mu}(\mathbf{x}). \tag{13.75.14}$$

But the coefficients of $y_1^{\lambda_1+n-1}y_2^{\lambda_2+n-2}...y_n^{\lambda_n+n-n}$ on the left hand side of (13.75.2) and on the right hand side of (13.75.2) must be equal. Since the former coefficient is $s_{\lambda/\mu}(\mathbf{x})$ (by (13.75.14)), and the latter coefficient is $\det\left(\left(h_{\lambda_i-\mu_j-i+j}(\mathbf{x})\right)_{i,j=1,2,\ldots,n}\right)$ (by (13.75.11)), this shows that

$$s_{\lambda/\mu}(\mathbf{x}) = \det\left(\left(h_{\lambda_i-\mu_j-i+j}(\mathbf{x})\right)_{i,j=1,2,\ldots,n}\right).$$

In other words, $s_{\lambda/\mu} = \det\left(\left(h_{\lambda_i-\mu_j-i+j}\right)_{i,j=1,2,\ldots,n}\right)$.

Now, forget that we fixed n, λ and μ. We thus have proven that if $n\in\mathbb{N}$, and if λ and μ are two partitions having at most n parts (each), then $s_{\lambda/\mu} = \det\left(\left(h_{\lambda_i-\mu_j-i+j}\right)_{i,j=1,2,\ldots,n}\right)$. Renaming n as ℓ in this claim, we obtain: If $\ell\in\mathbb{N}$, and if λ and μ are two partitions having at most ℓ parts (each), then

$$s_{\lambda/\mu} = \det\left(\left(h_{\lambda_i-\mu_j-i+j}\right)_{i,j=1,2,\ldots,\ell}\right). \tag{13.75.15}$$

This proves (2.4.16).

Now it remains to prove (2.4.17). Let $\ell\in\mathbb{N}$, and let λ and μ be two partitions having at most ℓ parts (each).

Let us first notice that every $m\in\mathbb{Z}$ satisfies

$$\omega(h_m) = e_m. \tag{13.75.16}$$

(Indeed, this follows from Proposition 2.4.3(b), applied to m instead of n.) But using (2.4.15), it is easy to see that

$$\omega\left(s_{\lambda/\mu}\right) = s_{\lambda^t/\mu^t}. \tag{13.75.17}$$

[641] Thus,

$$\begin{aligned} s_{\lambda^t/\mu^t} &= \omega\left(s_{\lambda/\mu}\right) = \omega\left(\det\left(\left(h_{\lambda_i-\mu_j-i+j}\right)_{i,j=1,2,\ldots,\ell}\right)\right) \qquad (\text{by (13.75.15)})\\ &= \det\left(\left(\underbrace{\omega\left(h_{\lambda_i-\mu_j-i+j}\right)}_{\substack{=e_{\lambda_i-\mu_j-i+j}\\ (\text{by (13.75.16)})}}\right)_{i,j=1,2,\ldots,\ell}\right)\\ &\qquad \left(\begin{array}{c}\text{since }\omega\text{ is a }\mathbf{k}\text{-algebra homomorphism, and thus}\\ \text{commutes with taking determinants}\end{array}\right)\\ &= \det\left(\left(e_{\lambda_i-\mu_j-i+j}\right)_{i,j=1,2,\ldots,\ell}\right). \end{aligned}$$

This proves (2.4.17). Therefore, the proof of Theorem 2.4.6 is complete.

---

[641] In fact, (13.75.17) follows immediately from (2.4.15) in the case when $\mu\subseteq\lambda$; but otherwise it follows from $s_{\lambda/\mu}=0$ and $s_{\lambda^t/\mu^t}=0$.

13.76. **Solution to Exercise 2.7.14.** *Solution to Exercise 2.7.14.* (a) The second identity of (2.4.15) shows that

$$S\left(s_{\lambda/\mu}\right) = (-1)^{|\lambda/\mu|} s_{\lambda^t/\mu^t} \tag{13.76.1}$$

whenever λ and μ are partitions satisfying $\mu \subseteq \lambda$. Hence,

$$S\left(s_{\lambda}\right) = (-1)^{|\lambda|} s_{\lambda^t} \qquad \text{for any partition } \lambda. \tag{13.76.2}$$

[*Proof of (13.76.2):* Let λ be any partition. Then, the empty partition $\varnothing$ clearly satisfies $\varnothing \subseteq \lambda$. Hence, (13.76.1) (applied to $\mu = \varnothing$) yields $S\left(s_{\lambda/\varnothing}\right) = (-1)^{|\lambda/\varnothing|} s_{\lambda^t/\varnothing^t}$. In view of $s_{\lambda/\varnothing} = s_\lambda$ and $\varnothing^t = \varnothing$, this rewrites as $S\left(s_{\lambda}\right) = (-1)^{|\lambda/\varnothing|} s_{\lambda^t/\varnothing}$. In view of $|\lambda/\varnothing| = |\lambda|$ and $s_{\lambda^t/\varnothing} = s_{\lambda^t}$, this rewrites as $S\left(s_{\lambda}\right) = (-1)^{|\lambda|} s_{\lambda^t}$. This proves (13.76.2).]

On the other hand, the definition of the Hall inner product $(\cdot,\cdot)$ shows that

$$\left(s_\lambda, s_\nu\right) = \delta_{\lambda,\nu} \qquad \text{for any two partitions } \lambda \text{ and } \nu. \tag{13.76.3}$$

Now, let $f \in \Lambda$ and $g \in \Lambda$.

Proposition 2.2.10 shows that the family $\left(s_\lambda\right)_{\lambda\in\operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, f can be written in the form $f = \sum_{\lambda\in\operatorname{Par}} a_\lambda s_\lambda$ for some family $\left(a_\lambda\right)_{\lambda\in\operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ of elements of $\mathbf{k}$ such that all but finitely many $\lambda \in \operatorname{Par}$ satisfy $a_\lambda = 0$. Consider this family $\left(a_\lambda\right)_{\lambda\in\operatorname{Par}}$.

Proposition 2.2.10 shows that the family $\left(s_\lambda\right)_{\lambda\in\operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, g can be written in the form $g = \sum_{\lambda\in\operatorname{Par}} b_\lambda s_\lambda$ for some family $\left(b_\lambda\right)_{\lambda\in\operatorname{Par}} \in \mathbf{k}^{\operatorname{Par}}$ of elements of $\mathbf{k}$ such that all but finitely many $\lambda \in \operatorname{Par}$ satisfy $b_\lambda = 0$. Consider this family $\left(b_\lambda\right)_{\lambda\in\operatorname{Par}}$.

The map $\operatorname{Par} \to \operatorname{Par},\ \lambda \mapsto \lambda^t$ is a bijection. (Indeed, this map is inverse to itself, since each partition λ satisfies $\left(\lambda^t\right)^t = \lambda$).

Applying the map S to both sides of the equality $f = \sum_{\lambda\in\operatorname{Par}} a_\lambda s_\lambda$, we obtain

$$\begin{aligned} S(f) &= S\left(\sum_{\lambda\in\operatorname{Par}} a_\lambda s_\lambda\right) = \sum_{\lambda\in\operatorname{Par}} a_\lambda \underbrace{S\left(s_\lambda\right)}_{\substack{=(-1)^{|\lambda|} s_{\lambda^t} \\ \text{(by (13.76.2))}}} \qquad \text{(since the map } S \text{ is } \mathbf{k}\text{-linear)} \\ &= \sum_{\lambda\in\operatorname{Par}} a_\lambda (-1)^{|\lambda|} s_{\lambda^t} = \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t} \underbrace{(-1)^{\left|\lambda^t\right|}}_{\substack{=(-1)^{|\lambda|} \\ \text{(since } \left|\lambda^t\right| = |\lambda|)}} \underbrace{s_{\left(\lambda^t\right)^t}}_{\substack{=s_\lambda \\ \text{(since } \left(\lambda^t\right)^t = \lambda)}} \\ &\qquad \left(\begin{array}{c}\text{here, we have substituted } \lambda^t \text{ for } \lambda \text{ in the sum, since} \\ \text{the map } \operatorname{Par} \to \operatorname{Par},\ \lambda \mapsto \lambda^t \text{ is a bijection}\end{array}\right) \\ &= \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t} (-1)^{|\lambda|} s_\lambda. \end{aligned}$$

The same argument (applied to g and b_λ instead of f and a_λ) yields

$$\begin{aligned} S(g) &= \sum_{\lambda\in\operatorname{Par}} b_{\lambda^t} (-1)^{|\lambda|} s_\lambda \qquad \left(\text{since } g = \sum_{\lambda\in\operatorname{Par}} b_\lambda s_\lambda\right) \\ &= \sum_{\mu\in\operatorname{Par}} b_{\mu^t} (-1)^{|\mu|} s_\mu \end{aligned}$$

(here, we have renamed the summation index λ as μ in the sum). Also,

$$g = \sum_{\lambda\in\operatorname{Par}} b_\lambda s_\lambda = \sum_{\mu\in\operatorname{Par}} b_\mu s_\mu$$

(here, we have renamed the summation index λ as μ in the sum).

Now,

$$\begin{aligned}
&\left(\underbrace{S\left(f\right)}_{=\sum_{\lambda\in\operatorname{Par}} a_{\lambda^t}(-1)^{|\lambda|} s_\lambda} , \underbrace{S\left(g\right)}_{=\sum_{\mu\in\operatorname{Par}} b_{\mu^t}(-1)^{|\mu|} s_\mu} \right) \\
&= \left(\sum_{\lambda\in\operatorname{Par}} a_{\lambda^t}\left(-1\right)^{|\lambda|} s_\lambda, \sum_{\mu\in\operatorname{Par}} b_{\mu^t}\left(-1\right)^{|\mu|} s_\mu \right) \\
&= \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t}\left(-1\right)^{|\lambda|} \sum_{\mu\in\operatorname{Par}} b_{\mu^t}\left(-1\right)^{|\mu|} \underbrace{\left(s_\lambda, s_\mu\right)}_{\substack{=\delta_{\lambda,\mu} \\ \text{(by (13.76.3),} \\ \text{applied to } \nu=\mu)}} \\
&\qquad \left(\text{since the Hall inner product } \left(\cdot,\cdot\right) \text{ is } \mathbf{k}\text{-bilinear}\right) \\
&= \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t}\left(-1\right)^{|\lambda|} \underbrace{\sum_{\mu\in\operatorname{Par}} b_{\mu^t}\left(-1\right)^{|\mu|} \delta_{\lambda,\mu}}_{\substack{=b_{\lambda^t}(-1)^{|\lambda|}\delta_{\lambda,\lambda}+\sum_{\substack{\mu\in\operatorname{Par};\\ \mu\neq\lambda}} b_{\mu^t}(-1)^{|\mu|}\delta_{\lambda,\mu} \\ \text{(here, we have split off the addend for } \mu=\lambda \text{ from the sum)}}} \\
&= \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t}\left(-1\right)^{|\lambda|} \left(b_{\lambda^t}\left(-1\right)^{|\lambda|} \underbrace{\delta_{\lambda,\lambda}}_{=1} + \sum_{\substack{\mu\in\operatorname{Par};\\ \mu\neq\lambda}} b_{\mu^t}\left(-1\right)^{|\mu|} \underbrace{\delta_{\lambda,\mu}}_{\substack{=0 \\ \text{(since } \lambda\neq\mu \\ \text{(since } \mu\neq\lambda\text{))}}} \right) \\
&= \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t}\left(-1\right)^{|\lambda|} \left(b_{\lambda^t}\left(-1\right)^{|\lambda|} + \underbrace{\sum_{\substack{\mu\in\operatorname{Par};\\ \mu\neq\lambda}} b_{\mu^t}\left(-1\right)^{|\mu|} 0}_{=0} \right) \\
&= \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t} \underbrace{\left(-1\right)^{|\lambda|} b_{\lambda^t}}_{=b_{\lambda^t}(-1)^{|\lambda|}} \left(-1\right)^{|\lambda|} = \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t} b_{\lambda^t} \underbrace{\left(-1\right)^{|\lambda|}\left(-1\right)^{|\lambda|}}_{\substack{=(-1)^{|\lambda|+|\lambda|}=1 \\ \text{(since } |\lambda|+|\lambda|=2|\lambda| \text{ is even)}}} = \sum_{\lambda\in\operatorname{Par}} a_{\lambda^t} b_{\lambda^t} = \sum_{\lambda\in\operatorname{Par}} a_\lambda b_\lambda
\end{aligned}$$

(here, we have substituted λ^t for λ in the sum, since the map $\operatorname{Par} \to \operatorname{Par},\ \lambda \mapsto \lambda^t$ is a bijection). Comparing this with

$$\begin{aligned}
&\left(\underbrace{f}_{=\sum_{\lambda\in\operatorname{Par}} a_\lambda s_\lambda}, \underbrace{g}_{=\sum_{\mu\in\operatorname{Par}} b_\mu s_\mu}\right) \\
&= \left(\sum_{\lambda\in\operatorname{Par}} a_\lambda s_\lambda, \sum_{\mu\in\operatorname{Par}} b_\mu s_\mu\right) = \sum_{\lambda\in\operatorname{Par}} a_\lambda \sum_{\mu\in\operatorname{Par}} b_\mu \underbrace{(s_\lambda, s_\mu)}_{\substack{=\delta_{\lambda,\mu} \\ \text{(by (13.76.3),} \\ \text{applied to } \nu=\mu)}} \\
&\qquad \text{(since the Hall inner product } (\cdot,\cdot) \text{ is } \mathbf{k}\text{-bilinear)} \\
&= \sum_{\lambda\in\operatorname{Par}} a_\lambda \underbrace{\sum_{\mu\in\operatorname{Par}} b_\mu \delta_{\lambda,\mu}}_{\substack{=b_\lambda\delta_{\lambda,\lambda} + \sum_{\substack{\mu\in\operatorname{Par}; \\ \mu\neq\lambda}} b_\mu\delta_{\lambda,\mu} \\ \text{(here, we have split off the addend for } \mu=\lambda \text{ from the sum)}}} \\
&= \sum_{\lambda\in\operatorname{Par}} a_\lambda \left(b_\lambda \underbrace{\delta_{\lambda,\lambda}}_{=1} + \sum_{\substack{\mu\in\operatorname{Par}; \\ \mu\neq\lambda}} b_\mu \underbrace{\delta_{\lambda,\mu}}_{\substack{=0 \\ \text{(since } \lambda\neq\mu \\ \text{(since } \mu\neq\lambda\text{))}}}\right) = \sum_{\lambda\in\operatorname{Par}} a_\lambda \left(b_\lambda + \underbrace{\sum_{\substack{\mu\in\operatorname{Par}; \\ \mu\neq\lambda}} b_\mu 0}_{=0}\right) = \sum_{\lambda\in\operatorname{Par}} a_\lambda b_\lambda,
\end{aligned}$$

we obtain $(S(f), S(g)) = (f, g)$. This solves Exercise 2.7.14(a).

(b) Let $n \in \mathbb{N}$ and $f \in \Lambda_n$. We know that the Hopf algebra Λ is graded; thus, its antipode S is a graded $\mathbf{k}$-linear map. Hence, $S(\Lambda_n) \subset \Lambda_n$. Now, from $f \in \Lambda_n$, we obtain $S(f) \in S(\Lambda_n) \subset \Lambda_n$. Hence, Exercise 2.5.13(b) (applied to $S(f)$ instead of f) yields $(h_n, S(f)) = (S(f))(1)$.

But Proposition 2.4.1(ii) yields $S(e_n) = (-1)^n h_n$. Hence,

$$\begin{aligned}
&\left(\underbrace{S(e_n)}_{=(-1)^n h_n}, S(f)\right) \\
&= ((-1)^n h_n, S(f)) = (-1)^n \cdot \underbrace{(h_n, S(f))}_{=(S(f))(1)} \qquad \text{(since the Hall inner product } (\cdot,\cdot) \text{ is } \mathbf{k}\text{-bilinear)} \\
&= (-1)^n \cdot (S(f))(1).
\end{aligned}$$

But Exercise 2.7.14(a) (applied to e_n and f instead of f and g) yields $(S(e_n), S(f)) = (e_n, f)$. Comparing these two equalities, we obtain $(e_n, f) = (-1)^n \cdot (S(f))(1)$. This solves Exercise 2.7.14(b).

13.77. **Solution to Exercise 2.8.4.**

Solution to Exercise 2.8.4. Let us first prove two lemmas:

Lemma 13.77.1. *Let $f \in \Lambda$ and $g \in \Lambda$. Assume that*

$$(s_\lambda, f) = (s_\lambda, g) \qquad \text{for each } \lambda \in \operatorname{Par}. \tag{13.77.1}$$

Then, $f = g$.

Proof of Lemma 13.77.1. The basis $(s_\lambda)_{\lambda\in\operatorname{Par}}$ of Λ is orthonormal with respect to the Hall inner product $(\cdot,\cdot)$ (by Definition 2.5.12). In other words, the two (identical) bases $(s_\lambda)_{\lambda\in\operatorname{Par}}$ and $(s_\lambda)_{\lambda\in\operatorname{Par}}$ of Λ are dual to each other with respect to the Hall inner product $(\cdot,\cdot)$.

Recall the following fundamental fact from linear algebra: If $\mathbf{k}$ is a commutative ring, if A is a $\mathbf{k}$-module, if $(\cdot,\cdot) : A \times A \to \mathbf{k}$ is a symmetric $\mathbf{k}$-bilinear form on A, and if $(u_\lambda)_{\lambda\in L}$ and $(v_\lambda)_{\lambda\in L}$ are two $\mathbf{k}$-bases of A

which are dual to each other with respect to the form $(\cdot, \cdot)$ (where L is some indexing set), then every $a \in A$ satisfies

$$a = \sum_{\lambda \in L} (u_\lambda, a) \, v_\lambda . \tag{13.77.2}$$

We can apply this fact to $A = \Lambda$, $L = \operatorname{Par}$, $(u_\lambda)_{\lambda \in L} = (s_\lambda)_{\lambda \in \operatorname{Par}}$ and $(v_\lambda)_{\lambda \in L} = (s_\lambda)_{\lambda \in \operatorname{Par}}$ (since the bases $(s_\lambda)_{\lambda \in \operatorname{Par}}$ and $(s_\lambda)_{\lambda \in \operatorname{Par}}$ of Λ are dual to each other with respect to the Hall inner product $(\cdot, \cdot)$). We thus conclude that every $a \in \Lambda$ satisfies

$$a = \sum_{\lambda \in \operatorname{Par}} (s_\lambda, a) \, s_\lambda . \tag{13.77.3}$$

Applying this to $a = f$, we obtain

$$f = \sum_{\lambda \in \operatorname{Par}} \underbrace{(s_\lambda, f)}_{\substack{=(s_\lambda, g) \\ \text{(by (13.77.1))}}} s_\lambda = \sum_{\lambda \in \operatorname{Par}} (s_\lambda, g) \, s_\lambda .$$

Comparing this with

$$g = \sum_{\lambda \in \operatorname{Par}} (s_\lambda, g) \, s_\lambda \qquad \text{(by (13.77.3), applied to } a = g\text{)} ,$$

we obtain $f = g$. This proves Lemma 13.77.1. □

Lemma 13.77.2. *Let $\gamma \in \operatorname{Par}$ and $k \in \mathbb{N}$.*

(a) *We have*

$$h_k^\perp s_\gamma = \sum_{\substack{\nu \in \operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_\nu . \tag{13.77.4}$$

(b) *We have*

$$e_k^\perp s_\gamma = \sum_{\substack{\nu \in \operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu . \tag{13.77.5}$$

Proof of Lemma 13.77.2. We know that every $f \in \Lambda$, $g \in \Lambda$ and $a \in \Lambda$ satisfy

$$\left(g, f^\perp (a)\right) = (fg, a) . \tag{13.77.6}$$

Indeed, this follows from Proposition 2.8.2(i) (applied to $A = \Lambda$), after we make the standard identification of Λ^o with Λ via the Hall inner product.

Recall that the basis $(s_\lambda)_{\lambda \in \operatorname{Par}}$ of Λ is orthonormal with respect to the Hall inner product $(\cdot, \cdot)$ (by Definition 2.5.12). In other words,

$$(s_\alpha, s_\beta) = \delta_{\alpha, \beta} \qquad \text{for every } (\alpha, \beta) \in \operatorname{Par} \times \operatorname{Par} . \tag{13.77.7}$$

(b) We claim that

$$\left(s_\lambda, e_k^\perp s_\gamma\right) = \left(s_\lambda, \sum_{\substack{\nu \in \operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu \right) \tag{13.77.8}$$

for every $\lambda \in \operatorname{Par}$.

Proof of (13.77.8): Let $\lambda \in \operatorname{Par}$. We have

$$e_k s_\lambda = s_\lambda e_k = \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{vertical } k\text{-strip}}} s_{\lambda^+} \tag{13.77.9}$$

(by (2.7.2), applied to $n = k$). But (13.77.6) (applied to $f = e_k$, $a = s_\gamma$ and $g = s_\lambda$) yields

$$\begin{aligned}\left(s_\lambda, e_k^\perp s_\gamma\right) = \left(e_k s_\lambda, s_\gamma\right) &= \left(\sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{vertical } k\text{-strip}}} s_{\lambda^+}, s_\gamma\right) && \text{(by (13.77.9))} \\ &= \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{vertical } k\text{-strip}}} \underbrace{\left(s_{\lambda^+}, s_\gamma\right)}_{\substack{=\delta_{\lambda^+,\gamma} \\ \text{(by (13.77.7), applied} \\ \text{to } (\alpha,\beta)=(\lambda^+,\gamma))}} && \text{(since the Hall inner product is } \mathbf{k}\text{-bilinear)} \\ &= \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{vertical } k\text{-strip}}} \delta_{\lambda^+,\gamma} = \begin{cases} 1, & \text{if } \gamma/\lambda \text{ is a vertical } k\text{-strip;} \\ 0, & \text{otherwise} \end{cases} . \end{aligned} \tag{13.77.10}$$

On the other hand, the Hall inner product is **k**-bilinear. Thus,

$$\begin{aligned}\left(s_\lambda, \sum_{\substack{\nu \in \mathrm{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu\right) &= \sum_{\substack{\nu \in \mathrm{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} \underbrace{\left(s_\lambda, s_\nu\right)}_{\substack{=\delta_{\lambda,\nu} \\ \text{(by (13.77.7), applied} \\ \text{to } (\alpha,\beta)=(\lambda,\nu))}} \\ &= \sum_{\substack{\nu \in \mathrm{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} \delta_{\lambda,\nu} = \begin{cases} 1, & \text{if } \gamma/\lambda \text{ is a vertical } k\text{-strip;} \\ 0, & \text{otherwise} \end{cases} .\end{aligned}$$

Comparing this with (13.77.10), we obtain

$$\left(s_\lambda, e_k^\perp s_\gamma\right) = \left(s_\lambda, \sum_{\substack{\nu \in \mathrm{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu\right).$$

Thus, (13.77.8) is proven.

Now, we have proven (13.77.8) for all $\lambda \in \mathrm{Par}$. Hence, Lemma 13.77.1 (applied to $f = e_k^\perp s_\gamma$ and $g = \sum_{\substack{\nu \in \mathrm{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu$) yields $e_k^\perp s_\gamma = \sum_{\substack{\nu \in \mathrm{Par}; \\ \gamma/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu$. This proves Lemma 13.77.2(b).

(a) We claim that

$$\left(s_\lambda, h_k^\perp s_\gamma\right) = \left(s_\lambda, \sum_{\substack{\nu \in \mathrm{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_\nu\right) \tag{13.77.11}$$

for every $\lambda \in \mathrm{Par}$.

Proof of (13.77.11): Let $\lambda \in \mathrm{Par}$. Then,

$$h_k s_\lambda = s_\lambda h_k = \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_{\lambda^+} \tag{13.77.12}$$

(by (2.7.1), applied to $n = k$). But (13.77.6) (applied to $f = h_k$, $a = s_\gamma$ and $g = s_\lambda$) yields

$$\begin{aligned}
\left(s_\lambda, h_k^\perp s_\gamma\right) = \left(h_k s_\lambda, s_\gamma\right) &= \left(\sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_{\lambda^+}, s_\gamma \right) \qquad \text{(by (13.77.12))} \\
&= \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } k\text{-strip}}} \underbrace{\left(s_{\lambda^+}, s_\gamma\right)}_{\substack{=\delta_{\lambda^+,\gamma} \\ \text{(by (13.77.7), applied} \\ \text{to } (\alpha,\beta)=\left(\lambda^+,\gamma\right))}} \qquad \text{(since the Hall inner product is } \mathbf{k}\text{-bilinear)} \\
&= \sum_{\substack{\lambda^+ : \lambda^+/\lambda \text{ is a} \\ \text{horizontal } k\text{-strip}}} \delta_{\lambda^+,\gamma} = \begin{cases} 1, & \text{if } \gamma/\lambda \text{ is a horizontal } k\text{-strip;} \\ 0, & \text{otherwise} \end{cases} . \qquad (13.77.13)
\end{aligned}$$

On the other hand, the Hall inner product is **k**-bilinear. Thus,

$$\begin{aligned}
\left(s_\lambda, \sum_{\substack{\nu\in\operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_\nu \right) &= \sum_{\substack{\nu\in\operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} \underbrace{\left(s_\lambda, s_\nu\right)}_{\substack{=\delta_{\lambda,\nu} \\ \text{(by (13.77.7), applied} \\ \text{to } (\alpha,\beta)=(\lambda,\nu))}} \\
&= \sum_{\substack{\nu\in\operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} \delta_{\lambda,\nu} = \begin{cases} 1, & \text{if } \gamma/\lambda \text{ is a horizontal } k\text{-strip;} \\ 0, & \text{otherwise} \end{cases} .
\end{aligned}$$

Comparing this with (13.77.13), we obtain

$$\left(s_\lambda, h_k^\perp s_\gamma\right) = \left(s_\lambda, \sum_{\substack{\nu\in\operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_\nu \right).$$

Thus, (13.77.11) is proven.

Now, we have proven (13.77.11) for all $\lambda \in \operatorname{Par}$. Hence, Lemma 13.77.1 (applied to $f = h_k^\perp s_\gamma$ and $g = \sum_{\substack{\nu\in\operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_\nu$) yields $h_k^\perp (s_\gamma) = \sum_{\substack{\nu\in\operatorname{Par}; \\ \gamma/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}} s_\nu$. This proves Lemma 13.77.2(a). □

Now, proving Proposition 2.8.3 is just a matter of renaming symbols in Lemma 13.77.2:

Proof of Proposition 2.8.3. Let λ be a partition. Let $n \in \mathbb{N}$. Then, Lemma 13.77.2(a) (applied to $\gamma = \lambda$ and $k = n$) yields

$$h_n^\perp s_\lambda = \sum_{\substack{\nu\in\operatorname{Par}; \\ \lambda/\nu \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_\nu = \sum_{\substack{\lambda^-\in\operatorname{Par}; \\ \lambda/\lambda^- \text{ is a} \\ \text{horizontal } n\text{-strip}}} s_{\lambda^-}$$

(here, we have renamed the summation index ν as λ^-). This is precisely the equality (2.8.3). Thus, (2.8.3) is proven.

Lemma 13.77.2(b) (applied to $\gamma = \lambda$ and $k = n$) yields

$$e_n^\perp s_\lambda = \sum_{\substack{\nu\in\operatorname{Par}; \\ \lambda/\nu \text{ is a} \\ \text{vertical } n\text{-strip}}} s_\nu = \sum_{\substack{\lambda^-\in\operatorname{Par}; \\ \lambda/\lambda^- \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^-}$$

(here, we have renamed the summation index ν as λ^-). This is precisely the equality (2.8.4). Thus, (2.8.4) is proven. This completes the proof of Proposition 2.8.3. □

Thus, Exercise 2.8.4 is solved.

13.78. **Solution to Exercise 2.8.6.** *Solution to Exercise 2.8.6.*

Let $(\Lambda_{\mathbb{Q}})_n$ denote the n-th graded component of the $\mathbb{Q}$-vector space $\Lambda_{\mathbb{Q}}$. We are going to work in $\Lambda_{\mathbb{Q}}$ in this solution, making use of the fact that both $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ and $(p_\lambda)_{\lambda\in\operatorname{Par}_n}$ are bases of the $\mathbb{Q}$-vector space $(\Lambda_{\mathbb{Q}})_n$ (due to Proposition 2.2.10). Of course, notions such as comultiplication, the antipode, skewing etc. are defined in $\Lambda_{\mathbb{Q}}$ just in the same way as they have been defined in Λ, and their properties are proven analogously.

Our solutions for both parts of the exercise rely on the fact that the trace of an endomorphism of a finite-dimensional vector space can be computed using any basis of the vector space. Specifically, we will be applying this fact to certain endomorphisms of $(\Lambda_{\mathbb{Q}})_n$, and as bases we will use $(p_\lambda)_{\lambda\in\operatorname{Par}_n}$ and $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$.

(a) The antipode S of $\Lambda_{\mathbb{Q}}$ is a graded map, and thus it restricts to an endomorphism of the $\mathbb{Q}$-vector space $(\Lambda_{\mathbb{Q}})_n$. Denote this endomorphism by S_n. We want to compute $\operatorname{trace}(S_n)$. (This is well-defined since $(\Lambda_{\mathbb{Q}})_n$ is a finite-dimensional $\mathbb{Q}$-vector space.)

From (2.4.15), we see that $S\left(s_{\lambda/\mu}\right) = (-1)^{|\lambda/\mu|} s_{\lambda^t/\mu^t}$ for any partitions λ and μ satisfying $\mu \subseteq \lambda$. In particular, $S(s_\lambda) = (-1)^{|\lambda|} s_{\lambda^t}$ for any partition λ. For any partition $\lambda \in \operatorname{Par}_n$, we now have $S_n(s_\lambda) = S(s_\lambda) = (-1)^{|\lambda|} s_{\lambda^t} = (-1)^n s_{\lambda^t}$. Thus, the matrix which represents the endomorphism S_n of $(\Lambda_{\mathbb{Q}})_n$ with respect to the basis $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ of $(\Lambda_{\mathbb{Q}})_n$ is the matrix whose (λ,μ)-th entry (for any $\lambda\in\operatorname{Par}_n$ and $\mu\in\operatorname{Par}_n$) is $(-1)^n$ whenever $\mu=\lambda^t$, and otherwise 0. But the trace $\operatorname{trace}(S_n)$ of S_n (by its definition) is the sum of the diagonal entries of this matrix; hence, this trace equals

$$\operatorname{trace}(S_n) = \sum_{\substack{\lambda\in\operatorname{Par}_n;\\ \lambda=\lambda^t}} (-1)^n = (-1)^n \underbrace{\left(\text{number of all } \lambda\in\operatorname{Par}_n \text{ satisfying } \lambda=\lambda^t\right)}_{=c(n)} = (-1)^n c(n).$$

On the other hand, every partition λ satisfies $S(p_\lambda) = (-1)^{\ell(\lambda)} p_\lambda$ (this follows from Proposition 2.4.1(i), after recalling that S is an algebra morphism and that $p_{(\lambda_1,\lambda_2,\ldots,\lambda_\ell)} = p_{\lambda_1}p_{\lambda_2}\ldots p_{\lambda_\ell}$). Hence, the matrix which represents the endomorphism S_n of $(\Lambda_{\mathbb{Q}})_n$ with respect to the basis $(p_\lambda)_{\lambda\in\operatorname{Par}_n}$ of $(\Lambda_{\mathbb{Q}})_n$ is a diagonal matrix, whose λ-th diagonal entry (for any $\lambda\in\operatorname{Par}_n$) is $(-1)^{\ell(\lambda)}$. But the trace $\operatorname{trace}(S_n)$ of S_n (by its definition) is the sum of the diagonal entries of this matrix; hence, this trace equals

$$\operatorname{trace}(S_n) = \sum_{\lambda\in\operatorname{Par}_n} (-1)^{\ell(\lambda)} = \sum_{k=0}^{n} \underbrace{\sum_{\substack{\lambda\in\operatorname{Par}_n;\\ \ell(\lambda)=k}} (-1)^k}_{=(-1)^k(\text{number of all } \lambda\in\operatorname{Par}_n \text{ satisfying } \ell(\lambda)=k)}$$
$$\left(\text{since } \ell(\lambda)\in\{0,1,\ldots,n\} \text{ for every } \lambda\in\operatorname{Par}_n\right)$$
$$= \sum_{k=0}^{n} (-1)^k \underbrace{\left(\text{number of all } \lambda\in\operatorname{Par}_n \text{ satisfying } \ell(\lambda)=k\right)}_{=p(n,k)} = \sum_{k=0}^{n} (-1)^k p(n,k).$$

Compared with $\operatorname{trace}(S_n) = (-1)^n c(n)$, this yields $(-1)^n c(n) = \sum_{k=0}^{n} (-1)^k p(n,k)$. This solves part (a) of the exercise.

(b) Consider the map $s_1 s_1^\perp : \Lambda\to\Lambda$ which sends every $f\in\Lambda$ to $s_1 s_1^\perp f$. This map $s_1 s_1^\perp$ is graded (because the map $s_1^\perp : \Lambda\to\Lambda$ lowers the degree of any homogeneous element by 1, while the map s_1 raises it back by 1) and thus restricts to an endomorphism of the $\mathbb{Q}$-vector space $(\Lambda_{\mathbb{Q}})_n$. Denote this endomorphism by P_n. We want to compute $\operatorname{trace}(P_n)$. (This is well-defined since $(\Lambda_{\mathbb{Q}})_n$ is a finite-dimensional $\mathbb{Q}$-vector space.)

In the following, if $\mathcal{A}$ is any statement, then $[\mathcal{A}]$ will denote the truth value of $\mathcal{A}$ (that is, 1 if $\mathcal{A}$ holds, and 0 if it doesn't).

We know that the basis $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ of $(\Lambda_{\mathbb{Q}})_n$ is orthonormal with respect to the Hall inner product (restricted to $(\Lambda_{\mathbb{Q}})_n$). Hence, for any $\lambda\in\operatorname{Par}_n$, we have

$$\begin{aligned}
&\left(\text{the } s_\lambda\text{-coordinate of } P_n s_\lambda \text{ with respect to this basis}\right)\\
&=\left(\underbrace{P_n s_\lambda}_{=s_1 s_1^\perp s_\lambda}, s_\lambda\right) = \left(s_1 s_1^\perp s_\lambda, s_\lambda\right) = \left(s_1^\perp s_\lambda, s_1^\perp s_\lambda\right)\\
&=\sum_{\mu\in\operatorname{Par}_{n-1}} \left(\underbrace{\left(s_1^\perp s_\lambda, s_\mu\right)}_{=(s_\lambda, s_1 s_\mu)}\right)^2\\
&\qquad\left(\begin{array}{c}\text{since } s_1^\perp s_\lambda\in(\Lambda_{\mathbb{Q}})_{n-1}\text{, and since the basis } (s_\mu)_{\mu\in\operatorname{Par}_{n-1}}\\ \text{of } (\Lambda_{\mathbb{Q}})_{n-1} \text{ is orthonormal with respect to the Hall}\\ \text{inner product (restricted to } (\Lambda_{\mathbb{Q}})_{n-1}\text{)}\end{array}\right)\\
&=\sum_{\mu\in\operatorname{Par}_{n-1}} \left(s_\lambda, s_1 s_\mu\right)^2 . \qquad (13.78.1)
\end{aligned}$$

Now, every $\mu\in\operatorname{Par}_{n-1}$ satisfies

$$\underbrace{s_1}_{=h_1} s_\mu = h_1 s_\mu \overset{(2.7.1)}{=} \sum_{\substack{\mu^+ \,:\, \mu^+/\mu \text{ is a}\\ \text{horizontal 1-strip}}} s_{\mu^+} = \sum_{\mu^+ \,:\, |\mu^+/\mu|=1} s_{\mu^+} = \sum_{\substack{\mu^+\in\operatorname{Par}_n;\\ \mu\subseteq\mu^+}} s_{\mu^+}.$$

Hence, every $\lambda\in\operatorname{Par}_n$ and $\mu\in\operatorname{Par}_{n-1}$ satisfy

$$\begin{aligned}
\left(s_\lambda, s_1 s_\mu\right) &= \left(s_\lambda, \sum_{\substack{\mu^+\in\operatorname{Par}_n;\\ \mu\subseteq\mu^+}} s_{\mu^+}\right) = \sum_{\substack{\mu^+\in\operatorname{Par}_n;\\ \mu\subseteq\mu^+}} \underbrace{\left(s_\lambda, s_{\mu^+}\right)}_{\substack{=[\lambda=\mu^+]\\ \text{(since the Schur functions}\\ \text{are orthonormal with respect}\\ \text{to the Hall inner product)}}} = \sum_{\substack{\mu^+\in\operatorname{Par}_n;\\ \mu\subseteq\mu^+}} \left[\lambda=\mu^+\right]\\
&= [\mu\subseteq\lambda] .
\end{aligned}$$

Now, consider again the basis $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ of $(\Lambda_{\mathbb{Q}})_n$. For every $\lambda\in\operatorname{Par}_n$, we have

$$\begin{aligned}
&\left(\text{the } s_\lambda\text{-coordinate of } P_n s_\lambda \text{ with respect to this basis}\right)\\
&=\sum_{\mu\in\operatorname{Par}_{n-1}} \left(\underbrace{\left(s_\lambda, s_1 s_\mu\right)}_{=[\mu\subseteq\lambda]}\right)^2 \qquad \text{(by (13.78.1))}\\
&=\sum_{\mu\in\operatorname{Par}_{n-1}} \underbrace{[\mu\subseteq\lambda]^2}_{=[\mu\subseteq\lambda]} = \sum_{\mu\in\operatorname{Par}_{n-1}} [\mu\subseteq\lambda]\\
&=\left(\text{the number of all } \mu\in\operatorname{Par}_{n-1} \text{ such that } \mu\subseteq\lambda\right)\\
&=\left(\text{the number of all ways to remove a single cell from } \lambda \text{ to obtain a partition}\right)\\
&=\left(\text{the number of all corners of the Ferrers diagram of } \lambda\right)\\
&=C(\lambda) . \qquad (13.78.2)
\end{aligned}$$

Now, consider the matrix which represents the endomorphism P_n of $(\Lambda_{\mathbb{Q}})_n$ with respect to the basis $(s_\lambda)_{\lambda\in\operatorname{Par}_n}$ of $(\Lambda_{\mathbb{Q}})_n$. For any $\lambda\in\operatorname{Par}_n$ and $\mu\in\operatorname{Par}_n$, the (λ,μ)-th entry of this matrix is

$$\left(\text{the } s_\lambda\text{-coordinate of } P_n s_\mu \text{ with respect to this basis}\right).$$

The trace $\operatorname{trace}(P_n)$ of P_n (by its definition) is the sum of the diagonal entries of this matrix; hence, this trace equals

$$\operatorname{trace}(P_n) = \sum_{\lambda \in \operatorname{Par}_n} \underbrace{(\text{the } s_\lambda\text{-coordinate of } P_n s_\lambda \text{ with respect to this basis})}_{\substack{=C(\lambda) \\ (\text{by } (13.78.2))}} = \sum_{\lambda \in \operatorname{Par}_n} C(\lambda).$$

On the other hand, it is easy to see that

$$s_1^\perp (p_n) = [n = 1] \qquad \text{for every positive integer } n \tag{13.78.3}$$

(in fact, recall that p_n is primitive, so that $\Delta(p_n) = p_n \otimes 1 + 1 \otimes p_n$ and thus $s_1^\perp(p_n) = \underbrace{(s_1, p_n)}_{=[n=1]} 1 + \underbrace{(s_1, 1)}_{=0} p_n = [n = 1]$). But the map $s_1^\perp : \Lambda \to \Lambda$ is a derivation (by Proposition 2.8.2(iv), since s_1 is primitive). Hence, every partition $\lambda = (\lambda_1, \lambda_2, ..., \lambda_\ell)$ with $\ell = \ell(\lambda)$ satisfies

$$\begin{aligned} s_1^\perp (p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell}) &= \sum_{k=1}^{\ell} p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_{k-1}} \underbrace{s_1^\perp (p_{\lambda_k})}_{\substack{=[\lambda_k=1] \\ (\text{by } (13.78.3))}} p_{\lambda_{k+1}} p_{\lambda_{k+2}} ... p_{\lambda_\ell} \\ &= \sum_{k=1}^{\ell} p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_{k-1}} [\lambda_k = 1] p_{\lambda_{k+1}} p_{\lambda_{k+2}} ... p_{\lambda_\ell} \end{aligned} \tag{13.78.4}$$

and

$$\begin{aligned} P_n p_\lambda &= s_1 s_1^\perp \underbrace{p_\lambda}_{=p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell}} = \underbrace{s_1}_{=p_1} \underbrace{s_1^\perp (p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell})}_{\substack{=\sum_{k=1}^{\ell} p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_{k-1}} [\lambda_k=1] p_{\lambda_{k+1}} p_{\lambda_{k+2}} ... p_{\lambda_\ell} \\ (\text{by } (13.78.4))}} \\ &= p_1 \sum_{k=1}^{\ell} p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_{k-1}} [\lambda_k = 1] p_{\lambda_{k+1}} p_{\lambda_{k+2}} ... p_{\lambda_\ell} \\ &= \sum_{k=1}^{\ell} p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_{k-1}} \underbrace{[\lambda_k = 1] p_1}_{\substack{=[\lambda_k=1] p_{\lambda_k} \\ (\text{because if } \lambda_k \neq 1, \text{ then both sides} \\ \text{of this are 0, and otherwise they} \\ \text{are clearly equal})}} p_{\lambda_{k+1}} p_{\lambda_{k+2}} ... p_{\lambda_\ell} \\ &= \sum_{k=1}^{\ell} p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_{k-1}} [\lambda_k = 1] p_{\lambda_k} p_{\lambda_{k+1}} p_{\lambda_{k+2}} ... p_{\lambda_\ell} = \sum_{k=1}^{\ell} [\lambda_k = 1] p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell} \\ &= \underbrace{\left(\sum_{k=1}^{\ell} [\lambda_k = 1] \right)}_{\substack{=(\text{the number of } k \in \{1,2,...,\ell\} \text{ such that } \lambda_k=1) \\ =(\text{the number of parts of } \lambda \text{ equal to } 1) \\ =\mu_1(\lambda)}} \underbrace{p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell}}_{=p_\lambda} \\ &= \mu_1(\lambda) p_\lambda. \end{aligned}$$

Hence, the matrix which represents the endomorphism P_n of $(\Lambda_{\mathbb{Q}})_n$ with respect to the basis $(p_\lambda)_{\lambda \in \operatorname{Par}_n}$ of $(\Lambda_{\mathbb{Q}})_n$ is a diagonal matrix, whose λ-th diagonal entry (for any $\lambda \in \operatorname{Par}_n$) is $\mu_1(\lambda)$. But the trace $\operatorname{trace}(P_n)$ of P_n (by its definition) is the sum of the diagonal entries of this matrix; hence, this trace equals

$$\operatorname{trace}(P_n) = \sum_{\lambda \in \operatorname{Par}_n} \mu_1(\lambda).$$

Compared with $\operatorname{trace}(P_n) = \sum_{\lambda \in \operatorname{Par}_n} C(\lambda)$, this yields $\sum_{\lambda \in \operatorname{Par}_n} C(\lambda) = \sum_{\lambda \in \operatorname{Par}_n} \mu_1(\lambda)$. This solves part (b) of the exercise.

13.79. **Solution to Exercise 2.8.7.** *Solution to Exercise 2.8.7.* We assume WLOG that $\mathbf{k} = \mathbb{Z}$, since it is enough to prove what we want over $\mathbb{Z}$.

(a) This is exactly the equality (2.4.14), and has already been proved. Here is a slightly different way to prove it:

Use the primitivity of p_n and Proposition 1.4.17 to obtain $S(p_n) = -p_n$ for every $n \geq 1$.

But the antipode S of Λ is an algebra anti-endomorphism (by Proposition 1.4.10), therefore an algebra endomorphism (by Exercise 1.5.8(a), since Λ is commutative). Hence, from the fact that $S(p_n) = -p_n$ for every $n \geq 1$, we can deduce by multiplicativity that $S(p_\lambda) = (-1)^{\ell(\lambda)} p_\lambda$ for every partition λ. Now recall (2.4.11), and the claim of part (a) follows.

(b) For this part of the exercise, we shall work in $\Lambda_\mathbb{R}$ and prove that the endomorphism ω of $\Lambda_\mathbb{R}$ is an isometry. This will clearly yield the analogous statement over $\mathbb{Z}$.

Recall that $\left\{ \dfrac{p_\lambda}{\sqrt{z_\lambda}} \right\}$ is an orthonormal basis of $\Lambda_\mathbb{R}$ (by Corollary 2.5.17(c)). Hence, in order to prove that the endomorphism ω of $\Lambda_\mathbb{R}$ is an isometry, it is enough to show that

$$\left(\omega\left(\frac{p_\lambda}{\sqrt{z_\lambda}}\right), \omega\left(\frac{p_\mu}{\sqrt{z_\mu}}\right) \right) = \left(\frac{p_\lambda}{\sqrt{z_\lambda}}, \frac{p_\mu}{\sqrt{z_\mu}} \right)$$

for any two partitions λ and μ. But this follows from part (a) and the fact that the basis $\left\{ \dfrac{p_\lambda}{\sqrt{z_\lambda}} \right\}$ is orthonormal. Hence, we have shown that the endomorphism ω of $\Lambda_\mathbb{R}$ is an isometry. The same holds therefore for the endomorphism ω of Λ, and thus part (b) of the exercise is solved.

(c) Part (c) of the exercise is precisely the statement of Proposition 2.4.3(f), which was proved in the solution to Exercise 2.4.4. Thus, we need not prove it again.

(d) follows from (b) and (c): Indeed, ω is a coalgebra morphism (by part (c) of the exercise). Now, Definition 2.8.1 yields

$$(\omega(a))^\perp \omega(b) = \sum_{(\omega(b))} (\omega(a), (\omega(b))_1)(\omega(b))_2 = \sum_{(b)} (\omega(a), \omega(b_1))\,\omega(b_2)$$

(since ω is a coalgebra morphism and thus we have $\sum_{(\omega(b))} (\omega(b))_1 \otimes (\omega(b))_2 = \sum_{(b)} \omega(b_1) \otimes \omega(b_2)$). Since ω is an isometry, this further simplifies to

$$(\omega(a))^\perp \omega(b) = \sum_{(b)} (a, b_1)\,\omega(b_2) = \omega\left(\underbrace{\sum_{(b)} (a, b_1)\, b_2}_{=a^\perp b} \right) = \omega\left(a^\perp b\right),$$

whence part (d) of the exercise is solved.

(e) and (f) follow from the fact that $s_\mu^\perp(s_\lambda) = s_{\lambda/\mu}$ (applied, respectively, to $\mu = \left(1^\ell\right)$ and to $\mu = (\lambda_1)$), and the fact that a parallel translation of a skew Ferrers shape doesn't change the corresponding skew Schur function.

(g) It should be clear that $S\left(s_{\lambda/\mu}\right) = (-1)^{|\lambda/\mu|} s_{\lambda^t/\mu^t}$ follows from $\omega\left(s_{\lambda/\mu}\right) = s_{\lambda^t/\mu^t}$, and this, in turn, follows from (d) if one knows that $\omega(s_\lambda) = s_{\lambda^t}$ for every partition λ.

So it remains to prove that $\omega(s_\lambda) = s_{\lambda^t}$ for every partition λ. To do so, we use induction over $|\lambda|$, and fix λ. Part (b) yields that $(\omega(s_\lambda), \omega(s_\lambda)) = 1$. Since $\omega(s_\lambda) \in \Lambda$, this shows that $\omega(s_\lambda) = \pm s_\nu$ for some partition ν (since a length-1 integral vector cannot have more than one nonzero coordinate). Hence, $\omega(s_\nu) = \pm s_\lambda$ (since ω is an involution). Writing λ as $(\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ with all of λ_1, λ_2, $\ldots$, λ_ℓ being positive, and writing ν as $(\nu_1, \nu_2, \nu_3, \ldots)$, we easily see (using (d) and (f)) that $\omega\left(e_{\nu_1}^\perp s_\lambda\right) = \pm h_{\nu_1}^\perp(s_\nu) = \pm s_{(\nu_2,\nu_3,\nu_4,\ldots)} \neq 0$, so that $e_{\nu_1}^\perp s_\lambda \neq 0$, and therefore $\ell \geq \nu_1$. On the other hand, (d) and (e) yield $\omega\left(h_\ell^\perp s_\nu\right) = \pm e_\ell^\perp(s_\lambda) = \pm s_{(\lambda_1-1,\lambda_2-1,\ldots,\lambda_\ell-1)} \neq 0$, thus $h_\ell^\perp s_\nu \neq 0$, so that $\ell \leq \nu_1$. Combined with $\ell \geq \nu_1$, this yields $\ell = \nu_1$. Hence, $h_\ell^\perp s_\nu = h_{\nu_1}^\perp s_{\nu_1} = s_{(\nu_2,\nu_3,\nu_4,\ldots)}$ (by (f)), so that

$$\omega\left(h_\ell^\perp s_\nu\right) = \omega\left(s_{(\nu_2,\nu_3,\nu_4,\ldots)}\right) = s_{(\nu_2,\nu_3,\nu_4,\ldots)^t}$$

by the induction assumption. Compared with

$$\omega\left(h_\ell^\perp s_\nu\right) = \pm e_\ell^\perp\left(s_\lambda\right) = \pm s_{(\lambda_1-1,\lambda_2-1,\ldots,\lambda_\ell-1)}$$

(a consequence of (d) and (e)), this yields $s_{(\nu_2,\nu_3,\nu_4,\ldots)^t} = \pm s_{(\lambda_1-1,\lambda_2-1,\ldots,\lambda_\ell-1)}$, from which it directly follows that $\pm = +$ and $(\nu_2,\nu_3,\nu_4,\ldots)^t = (\lambda_1-1,\lambda_2-1,\ldots,\lambda_\ell-1)$. This quickly yields $\nu = \lambda^t$, so that $\omega(s_\lambda) = \pm s_\nu$ becomes $\omega(s_\lambda) = s_{\lambda^t}$ (the $\pm$ in $\omega(s_\lambda) = \pm s_\nu$ is the same as in $s_{(\nu_2,\nu_3,\nu_4,\ldots)^t} = \pm s_{(\lambda_1-1,\lambda_2-1,\ldots,\lambda_\ell-1)}$), so we are done.

13.80. **Solution to Exercise 2.8.8.** *Solution to Exercise 2.8.8.* Proposition 2.3.6(i) yields $\Delta p_n = 1 \otimes p_n + p_n \otimes 1$. Comparing this with $\Delta p_n = \sum_{(p_n)} (p_n)_1 \otimes (p_n)_2$ (here, we are using the Sweedler notation), we obtain

$$\sum_{(p_n)} (p_n)_1 \otimes (p_n)_2 = 1 \otimes p_n + p_n \otimes 1. \tag{13.80.1}$$

(a) Proposition 2.4.1(i) yields $S(p_n) = -p_n$.

But $p_n \in \Lambda_n$. Hence, Exercise 2.7.14(b) (applied to $f = p_n$) yields

$$\begin{aligned}(e_n, p_n) &= (-1)^n \cdot \underbrace{(S(p_n))}_{=-p_n}(1) = (-1)^n \cdot \underbrace{(-p_n)(1)}_{=-p_n(1)} \\ &= (-1)^n \cdot (-p_n(1)) = \underbrace{-(-1)^n}_{\substack{=(-1)^{n+1}=(-1)^{n-1} \\ (\text{since } n+1\equiv n-1 \bmod 2)}} \cdot \underbrace{p_n(1)}_{\substack{=1^n \\ (\text{by the definition of } p_n)}} \\ &= (-1)^{n-1} \cdot \underbrace{1^n}_{=1} = (-1)^{n-1}.\end{aligned}$$

This solves Exercise 2.8.8(a).

(b) Let $m \in \mathbb{N}$ satisfy $m \neq n$. Then, $e_m \in \Lambda_m$ and $p_n \in \Lambda_n$. But m and n are two distinct nonnegative integers (since $m \neq n$). Hence, Exercise 2.5.13(a) (applied to m, n, e_m and p_n instead of n, m, f and g) yields $(e_m, p_n) = 0$. This solves Exercise 2.8.8(b).

(c) We have $n \neq 0$ (since n is positive). Thus, n and 0 are two distinct nonnegative integers. Hence, Exercise 2.5.13(a) (applied to $m = 0$, $f = e_n$ and $g = 1$) yields $(e_n, 1) = 0$ (since $e_n \in \Lambda_n$ and $1 \in \Lambda_0$).

By the definition of $e_n^\perp p_n$, we have

$$\begin{aligned}e_n^\perp p_n &= \sum_{(p_n)} (e_n, (p_n)_1) \cdot (p_n)_2 = \underbrace{(e_n, 1)}_{=0} \cdot p_n + \underbrace{(e_n, p_n)}_{\substack{=(-1)^{n-1} \\ (\text{by Exercise 2.8.8(a)})}} \cdot 1 \\ &\qquad \left(\text{since } \sum_{(p_n)} (p_n)_1 \otimes (p_n)_2 = 1 \otimes p_n + p_n \otimes 1 \text{ (by (13.80.1))}\right) \\ &= \underbrace{0 \cdot p_n}_{=0} + (-1)^{n-1} = (-1)^{n-1}.\end{aligned}$$

This solves Exercise 2.8.8(c).

(d) Let m be a positive integer satisfying $m \neq n$. Then, Exercise 2.8.8(b) yields $(e_m, p_n) = 0$.

We have $m \neq 0$ (since m is positive). Thus, m and 0 are two distinct nonnegative integers. Hence, Exercise 2.5.13(a) (applied to m, 0, e_m and 1 instead of n, m, f and g) yields $(e_m, 1) = 0$ (since $e_m \in \Lambda_m$ and $1 \in \Lambda_0$).

By the definition of $e_m^\perp p_n$, we have

$$\begin{aligned} e_m^\perp p_n &= \sum_{(p_n)} \left(e_m, (p_n)_1\right) \cdot (p_n)_2 = \underbrace{(e_m, 1)}_{=0} \cdot p_n + \underbrace{(e_m, p_n)}_{=0} \cdot 1 \\ &\qquad \left(\text{since } \sum_{(p_n)} (p_n)_1 \otimes (p_n)_2 = 1 \otimes p_n + p_n \otimes 1 \text{ (by (13.80.1))}\right) \\ &= \underbrace{0 \cdot p_n}_{=0} + \underbrace{0 \cdot 1}_{=0} = 0. \end{aligned}$$

This solves Exercise 2.8.8(d).

13.81. **Solution to Exercise 2.9.1.** *Solution to Exercise 2.9.1.* (a) The claim that the sum $\sum_{i \in \mathbb{N}} (-1)^i h_{m+i} e_i^\perp f$ is convergent is very easy to see: Any given $f \in \Lambda = \bigoplus_{n \in \mathbb{N}} \Lambda_n$ lives in a finite direct sum $\bigoplus_{n=0}^m \Lambda_n \subset \Lambda$; if we take $i \in \mathbb{N}$ higher than m, then $e_i^\perp f = 0$ for degree reasons[642] and therefore $(-1)^i h_{m+i} e_i^\perp f = 0$.

The claim that the map $\mathbf{B}_m$ is $\mathbf{k}$-linear is obvious. Exercise 2.9.1(a) is solved.

(c) Exercise 2.9.1(c) makes three claims. Let us first prove the first of them: the identity (2.9.1).

Proof of (2.9.1): Let $\lambda = (\lambda_1, \lambda_2, \lambda_3, ...)$ be a partition having at most n parts. Then,

$$\begin{aligned} s_\lambda = s_{\lambda / \varnothing} &\overset{(2.4.16)}{=} \det\left(\left(h_{\lambda_i - \varnothing_j - i + j}\right)_{i,j=1,2,\ldots,n} \right) = \det\left(\left(h_{\lambda_i - i + j}\right)_{i,j=1,2,\ldots,n} \right) \qquad (\text{since } \varnothing_j = 0) \\ &= \overline{s}_{(\lambda_1, \lambda_2, \ldots, \lambda_n)} \qquad \left(\text{by the definition of } \overline{s}_{(\lambda_1, \lambda_2, \ldots, \lambda_n)}\right). \end{aligned}$$

This proves (2.9.1).

Next, we will show that for every n-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{Z}^n$, the symmetric function $\overline{s}_{(\alpha_1, \alpha_2, \ldots, \alpha_n)}$ either is 0 or equals $\pm s_\nu$ for some partition ν having at most n parts.

Proof. Let $(\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{Z}^n$ be any n-tuple. The definition of $\overline{s}_{(\alpha_1, \alpha_2, \ldots, \alpha_n)}$ yields

$$\overline{s}_{(\alpha_1, \alpha_2, \ldots, \alpha_n)} = \det\left(\left(h_{\alpha_i - i + j}\right)_{i,j=1,2,\ldots,n} \right).$$

If the n integers $\alpha_1 - 1$, $\alpha_2 - 2$, ..., $\alpha_n - n$ are not distinct, then the matrix $\left(h_{\alpha_i - i + j}\right)_{i,j=1,2,\ldots,n}$ has two equal rows and thus its determinant is 0, so that $\overline{s}_{(\alpha_1, \alpha_2, \ldots, \alpha_n)} = \det\left(\left(h_{\alpha_i - i + j}\right)_{i,j=1,2,\ldots,n} \right) = 0$ in this case. So the claim is proven in this case, and this is a case we do not need to address anymore. Thus, assume WLOG that the n integers $\alpha_1 - 1$, $\alpha_2 - 2$, ..., $\alpha_n - n$ are distinct. Hence, there exists a (unique) permutation $\tau \in \mathfrak{S}_n$ satisfying $\alpha_{\tau(1)} - \tau(1) > \alpha_{\tau(2)} - \tau(2) > ... > \alpha_{\tau(n)} - \tau(n)$. Consider this τ.

Define an n-tuple $(\gamma_1, \gamma_2, ..., \gamma_n) \in \mathbb{Z}^n$ by setting

$$\gamma_i = \alpha_{\tau(i)} - \tau(i) + i \qquad \text{for every } i \in \{1, 2, ..., n\}.$$

Then, it is easy to see that $\gamma_1 \geq \gamma_2 \geq ... \geq \gamma_n$. [643] Moreover, every $i \in \{1, 2, ..., n\}$ satisfies $\gamma_i - i = \alpha_{\tau(i)} - \tau(i)$ (by the definition of γ_i), and so the matrix $\left(h_{\gamma_i - i + j}\right)_{i,j=1,2,\ldots,n}$ is obtained from the matrix $\left(h_{\alpha_i - i + j}\right)_{i,j=1,2,\ldots,n}$ by permuting its rows according to the permutation τ. Since permuting the rows of a matrix multiplies the determinant of the matrix by the sign of the permutation, we thus see

$$\det\left(\left(h_{\gamma_i - i + j}\right)_{i,j=1,2,\ldots,n} \right) = (-1)^\tau \underbrace{\det\left(\left(h_{\alpha_i - i + j}\right)_{i,j=1,2,\ldots,n} \right)}_{= \overline{s}_{(\alpha_1, \alpha_2, \ldots, \alpha_n)}} = (-1)^\tau \overline{s}_{(\alpha_1, \alpha_2, \ldots, \alpha_n)},$$

so that

$$\overline{s}_{(\alpha_1, \alpha_2, \ldots, \alpha_n)} = (-1)^\tau \det\left(\left(h_{\gamma_i - i + j}\right)_{i,j=1,2,\ldots,n} \right). \tag{13.81.1}$$

If $\gamma_n < 0$, then the matrix $\left(h_{\gamma_i - i + j}\right)_{i,j=1,2,\ldots,n}$ on the right hand side of this equality has its n-th row consist of zeroes only, which implies that the determinant of this matrix is 0, and thus (13.81.1) becomes

[642] In fact, the map $e_i^\perp$ lowers degree by i, and thus annihilates $\bigoplus_{n=0}^m \Lambda_n$ when $i > m$.

[643] To prove this, it is enough to show that $\gamma_i \geq \gamma_{i+1}$ for every $i \in \{1, 2, ..., n-1\}$. But this simplifies to $\alpha_{\tau(i)} - \tau(i) \geq \alpha_{\tau(i+1)} - \tau(i+1) + 1$ (upon adding i), and this follows from $\alpha_{\tau(i)} - \tau(i) > \alpha_{\tau(i+1)} - \tau(i+1)$.

$\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = 0$. Hence, we are done in the case $\gamma_n < 0$. So assume WLOG that we don't have $\gamma_n < 0$. Thus, $\gamma_n \geq 0$. Combined with $\gamma_1 \geq \gamma_2 \geq \ldots \geq \gamma_n$, this yields that $(\gamma_1, \gamma_2, \ldots, \gamma_n)$ is a partition. This partition satisfies

$$s_{(\gamma_1,\gamma_2,\ldots,\gamma_n)} = s_{(\gamma_1,\gamma_2,\ldots,\gamma_n)/\varnothing} \overset{(2.4.16)}{=} \det\left(\left(h_{\gamma_i-\varnothing_j-i+j}\right)_{i,j=1,2,\ldots,n}\right) = \det\left(\left(h_{\gamma_i-i+j}\right)_{i,j=1,2,\ldots,n}\right)$$

(since $\varnothing_j = 0$ for all j). Thus, (13.81.1) becomes

$$\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = (-1)^{\tau} \underbrace{\det\left(\left(h_{\gamma_i-i+j}\right)_{i,j=1,2,\ldots,n}\right)}_{=s_{(\gamma_1,\gamma_2,\ldots,\gamma_n)}} = (-1)^{\tau} s_{(\gamma_1,\gamma_2,\ldots,\gamma_n)},$$

and therefore the symmetric function $\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$ equals $\pm s_\nu$ for some partition ν having at most n parts (namely, the partition ν is $(\gamma_1, \gamma_2, \ldots, \gamma_n)$, and the $\pm$ sign is $(-1)^\tau$).

We thus have shown that for every n-tuple $(\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{Z}^n$, the symmetric function $\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$ either is 0 or equals $\pm s_\nu$ for some partition ν having at most n parts.

In order to complete the solution of Exercise 2.9.1(c), it now remains to prove (2.9.2).

Proof of (2.9.2): Let $(\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{Z}^n$ and $(\beta_1, \beta_2, \ldots, \beta_n) \in \mathbb{N}^n$ be two n-tuples. We need to prove that (2.9.2) holds.

The definition of $\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$ yields

$$\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = \det\left(\left(h_{\alpha_i-i+j}\right)_{i,j=1,2,\ldots,n}\right).$$

If the n integers $\alpha_1 - 1$, $\alpha_2 - 2$, ..., $\alpha_n - n$ are not distinct, then (2.9.2) holds (because in this case, the matrices $\left(h_{\alpha_i-i+j}\right)_{i,j=1,2,\ldots,n}$ and $\left(h_{\alpha_i-\beta_j-i+j}\right)_{i,j=1,2,\ldots,n}$ have two equal rows each, so their determinants vanish, rendering both sides of (2.9.2) equal to zero[644]). Thus, we WLOG assume that the n integers $\alpha_1 - 1$, $\alpha_2 - 2$, ..., $\alpha_n - n$ are distinct. Thus, there exists a (unique) permutation $\tau \in \mathfrak{S}_n$ satisfying $\alpha_{\tau(1)} - \tau(1) > \alpha_{\tau(2)} - \tau(2) > \ldots > \alpha_{\tau(n)} - \tau(n)$. Consider this τ, and define an n-tuple $(\gamma_1, \gamma_2, \ldots, \gamma_n) \in \mathbb{Z}^n$ by setting

$$\gamma_i = \alpha_{\tau(i)} - \tau(i) + i \qquad \text{for every } i \in \{1, 2, \ldots, n\}.$$

Then, it is easy to see that $\gamma_1 \geq \gamma_2 \geq \ldots \geq \gamma_n$. Moreover, the matrix $\left(h_{\gamma_i-i+j}\right)_{i,j=1,2,\ldots,n}$ is obtained from the matrix $\left(h_{\alpha_i-i+j}\right)_{i,j=1,2,\ldots,n}$ by permuting its rows according to the permutation τ (because every $i \in \{1, 2, \ldots, n\}$ satisfies $\gamma_i - i = \alpha_{\tau(i)} - \tau(i)$). This leads to (13.81.1) again (as in the previous proof), so that

$$\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = (-1)^{\tau} \underbrace{\det\left(\left(h_{\gamma_i-i+j}\right)_{i,j=1,2,\ldots,n}\right)}_{=\overline{s}_{(\gamma_1,\gamma_2,\ldots,\gamma_n)}} = (-1)^{\tau} \overline{s}_{(\gamma_1,\gamma_2,\ldots,\gamma_n)}.$$

This equality, along with

$$\det\left(\left(h_{\alpha_i-\beta_j-i+j}\right)_{i,j=1,2,\ldots,n}\right) = (-1)^{\tau} \det\left(\left(h_{\gamma_i-\beta_j-i+j}\right)_{i,j=1,2,\ldots,n}\right)$$

(which, again, follows from the fact that the matrix on the right hand side is obtained from the matrix on the left hand side by permuting the rows according to τ), shows that in order to prove (2.9.2), it is enough to show that

$$\overline{s}^{\perp}_{(\beta_1,\beta_2,\ldots,\beta_n)} \overline{s}_{(\gamma_1,\gamma_2,\ldots,\gamma_n)} = \det\left(\left(h_{\gamma_i-\beta_j-i+j}\right)_{i,j=1,2,\ldots,n}\right).$$

But this is the same equality as (2.9.2), except with $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ replaced by $(\gamma_1, \gamma_2, \ldots, \gamma_n)$. The advantage of $(\gamma_1, \gamma_2, \ldots, \gamma_n)$ over $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ is that we know that $\gamma_1 \geq \gamma_2 \geq \ldots \geq \gamma_n$ (while the analogous chain of inequalities $\alpha_1 \geq \alpha_2 \geq \ldots \geq \alpha_n$ does not necessarily hold). So, we can **WLOG assume that** $\alpha_1 \geq \alpha_2 \geq \ldots \geq \alpha_n$ (because otherwise, we can replace $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ by $(\gamma_1, \gamma_2, \ldots, \gamma_n)$). Assume this.

If $\alpha_n < 0$, then both matrices $\left(h_{\alpha_i-i+j}\right)_{i,j=1,2,\ldots,n}$ and $\left(h_{\alpha_i-\beta_j-i+j}\right)_{i,j=1,2,\ldots,n}$ have their n-th row consisting of only zeroes, and so their determinants both vanish, which shows that both sides of the equality (2.9.2) are zero[645]. So this is a case in which (2.9.2) trivially holds. We thus assume WLOG that we are

[644] The left hand side is affected because of $\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = \det\left(\left(h_{\alpha_i-i+j}\right)_{i,j=1,2,\ldots,n}\right)$.

[645] For the left hand side, this is because of $\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = \det\left(\left(h_{\alpha_i-i+j}\right)_{i,j=1,2,\ldots,n}\right)$.

not in this case; hence, we don't have $\alpha_n < 0$, so we have $\alpha_n \geq 0$. Combined with $\alpha_1 \geq \alpha_2 \geq ... \geq \alpha_n$, this yields that $(\alpha_1, \alpha_2, ..., \alpha_n)$ is a partition.

We have

$$\overline{s}_{(\beta_1,\beta_2,...,\beta_n)} = \det\left(\left(h_{\beta_i-i+j}\right)_{i,j=1,2,...,n}\right).$$

If the n integers $\beta_1 - 1$, $\beta_2 - 2$, ..., $\beta_n - n$ are not distinct, then (2.9.2) holds (because in this case, the matrix $\left(h_{\beta_i-i+j}\right)_{i,j=1,2,...,n}$ has two equal rows while the matrix $\left(h_{\alpha_i-\beta_j-i+j}\right)_{i,j=1,2,...,n}$ has two equal columns; thus, both of these matrices have determinant 0, so that both sides of (2.9.2) equal to zero[646]). Thus, we WLOG assume that the n integers $\beta_1 - 1$, $\beta_2 - 2$, ..., $\beta_n - n$ are distinct. Thus, there exists a (unique) permutation $\zeta \in \mathfrak{S}_n$ satisfying $\beta_{\zeta(1)} - \zeta(1) > \beta_{\zeta(2)} - \zeta(2) > ... > \beta_{\zeta(n)} - \zeta(n)$. Consider this ζ.

Define an n-tuple $(\delta_1, \delta_2, ..., \delta_n) \in \mathbb{Z}^n$ by setting

$$\delta_j = \beta_{\zeta(j)} - \zeta(j) + j \qquad \text{for every } j \in \{1, 2, ..., n\}.$$

Then, it is easy to see that $\delta_1 \geq \delta_2 \geq ... \geq \delta_n \geq 0$ [647]. Thus, $(\delta_1, \delta_2, ..., \delta_n)$ is a partition.

The matrix $\left(h_{\delta_i-i+j}\right)_{i,j=1,2,...,n}$ is obtained from the matrix $\left(h_{\beta_i-i+j}\right)_{i,j=1,2,...,n}$ by permuting its rows according to the permutation ζ (since the definition of δ_i yields $\delta_i = \beta_{\zeta(i)} - \zeta(i) + i$, thus $\delta_i - i = \beta_{\zeta(i)} - \zeta(i)$ for every $i \in \{1, 2, ..., n\}$). This leads to $\det\left(\left(h_{\delta_i-i+j}\right)_{i,j=1,2,...,n}\right) = (-1)^\zeta \underbrace{\det\left(\left(h_{\beta_i-i+j}\right)_{i,j=1,2,...,n}\right)}_{=\overline{s}_{(\beta_1,\beta_2,...,\beta_n)}} = (-1)^\zeta \overline{s}_{(\beta_1,\beta_2,...,\beta_n)}$ and thus

$$\overline{s}_{(\beta_1,\beta_2,...,\beta_n)} = (-1)^\zeta \underbrace{\det\left(\left(h_{\delta_i-i+j}\right)_{i,j=1,2,...,n}\right)}_{=\overline{s}_{(\delta_1,\delta_2,...,\delta_n)}} = (-1)^\zeta \overline{s}_{(\delta_1,\delta_2,...,\delta_n)}.$$

This equality, and the equality

$$\det\left(\left(h_{\alpha_i-\beta_j-i+j}\right)_{i,j=1,2,...,n}\right) = (-1)^\zeta \det\left(\left(h_{\alpha_i-\delta_j-i+j}\right)_{i,j=1,2,...,n}\right)$$

(this time because the matrix on the right hand side is obtained from that on the left hand side by permuting its **columns** according to ζ) show that in order to prove (2.9.2), it is enough to show that

$$\overline{s}^\perp_{(\delta_1,\delta_2,...,\delta_n)} \overline{s}_{(\alpha_1,\alpha_2,...,\alpha_n)} = \det\left(\left(h_{\alpha_i-\delta_j-i+j}\right)_{i,j=1,2,...,n}\right).$$

This is, of course, the same equality as (2.9.2), except with $(\beta_1, \beta_2, \ldots, \beta_n)$ replaced by $(\delta_1, \delta_2, ..., \delta_n)$. The advantage of $(\delta_1, \delta_2, ..., \delta_n)$ over $(\beta_1, \beta_2, \ldots, \beta_n)$ is that we know that $(\delta_1, \delta_2, ..., \delta_n)$ is a partition. So, we can **WLOG assume that** $(\beta_1, \beta_2, ..., \beta_n)$ is a partition (because otherwise, we can replace $(\beta_1, \beta_2, \ldots, \beta_n)$ by $(\delta_1, \delta_2, ..., \delta_n)$). Assume this.

Through a series of WLOG assumptions, we have now ensured that both $(\alpha_1, \alpha_2, \ldots, \alpha_n)$ and $(\beta_1, \beta_2, \ldots, \beta_n)$ are partitions. Thus,

$$\begin{aligned} s_{(\alpha_1,\alpha_2,...,\alpha_n)} &= s_{(\alpha_1,\alpha_2,...,\alpha_n)/\varnothing} \overset{(2.4.16)}{=} \det\left(\left(h_{\alpha_i-\varnothing_j-i+j}\right)_{i,j=1,2,...,n}\right) \\ &= \det\left(\left(h_{\alpha_i-i+j}\right)_{i,j=1,2,...,n}\right) \qquad (\text{since } \varnothing_j = 0) \\ &= \overline{s}_{(\alpha_1,\alpha_2,...,\alpha_n)}, \end{aligned}$$

so that $\overline{s}_{(\alpha_1,\alpha_2,...,\alpha_n)} = s_{(\alpha_1,\alpha_2,...,\alpha_n)}$. Similarly $\overline{s}_{(\beta_1,\beta_2,...,\beta_n)} = s_{(\beta_1,\beta_2,...,\beta_n)}$. Hence,

$$\begin{aligned} \overline{s}^\perp_{(\beta_1,\beta_2,...,\beta_n)} \overline{s}_{(\alpha_1,\alpha_2,...,\alpha_n)} &= s^\perp_{(\beta_1,\beta_2,...,\beta_n)} s_{(\alpha_1,\alpha_2,...,\alpha_n)} = s_{(\alpha_1,\alpha_2,...,\alpha_n)/(\beta_1,\beta_2,...,\beta_n)} \\ &\overset{(2.4.16)}{=} \det\left(\left(h_{\alpha_i-\beta_j-i+j}\right)_{i,j=1,2,...,n}\right). \end{aligned}$$

[646] This time, the reason why this causes the left hand side to be zero is the identity $\overline{s}_{(\beta_1,\beta_2,...,\beta_n)} = \det\left(\left(h_{\beta_i-i+j}\right)_{i,j=1,2,...,n}\right)$.

[647] The $\delta_1 \geq \delta_2 \geq ... \geq \delta_n$ part here is proven like the similar inequalities $\gamma_1 \geq \gamma_2 \geq ... \geq \gamma_n$ shown above; but the $\delta_n \geq 0$ part might require explanation. It stems from the fact that $\delta_n = \beta_{\zeta(n)} - \underbrace{\zeta(n)}_{\leq n} + n \geq \beta_{\zeta(n)} - n + n = \beta_{\zeta(n)} \geq 0$ (because we have assumed $(\beta_1, \beta_2, ..., \beta_n) \in \mathbb{N}^n$).

This proves (2.9.2) and thus completes the proof of Exercise 2.9.1(c).

(d) In the following, we use the so-called *Iverson bracket notation*: For every assertion $\mathcal{A}$, we let $[\mathcal{A}]$ denote the integer $\begin{cases} 1, & \text{if } \mathcal{A} \text{ is true;} \\ 0, & \text{if } \mathcal{A} \text{ is false} \end{cases}$. (This integer is called the *truth value* of $\mathcal{A}$.)

Before we come to the solution of Exercise 2.9.1(d), let us recall a general fact about determinants:

- Every commutative ring A, every positive integer N and every matrix $(\beta_{i,j})_{i,j=1,2,\ldots,N} \in A^{N\times N}$ satisfy

$$\det\left((\beta_{i,j})_{i,j=1,2,\ldots,N}\right) = \sum_{k=1}^{N} (-1)^{k-1} \beta_{1,k} \det\left(\left(\beta_{i+1,j+[j\geq k]}\right)_{i,j=1,2,\ldots,N-1}\right). \tag{13.81.2}$$

(This is just one possible way to write the Laplace expansion formula for the expansion of the determinant of a matrix with respect to its first row.)

Let us now solve Exercise 2.9.1(d). Let $n \in \mathbb{N}$, let $m \in \mathbb{Z}$ and let $(\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{Z}^n$. We must prove (2.9.3).

Define an $(n+1)$-tuple $(\gamma_1, \gamma_2, ..., \gamma_{n+1}) \in \mathbb{Z}^{n+1}$ by $(\gamma_1, \gamma_2, ..., \gamma_{n+1}) = (m, \alpha_1, \alpha_2, ..., \alpha_n)$. Then, $\gamma_1 = m$, whereas every $i \in \{1, 2, ..., n\}$ satisfies $\gamma_{i+1} = \alpha_i$. Since $(m, \alpha_1, \alpha_2, ..., \alpha_n) = (\gamma_1, \gamma_2, ..., \gamma_{n+1})$, we have

$$\begin{aligned}
\overline{s}_{(m,\alpha_1,\alpha_2,...,\alpha_n)} &= \overline{s}_{(\gamma_1,\gamma_2,...,\gamma_{n+1})} = \det\left(\left(h_{\gamma_i - i + j}\right)_{i,j=1,2,...,n+1}\right) \qquad \left(\text{by the definition of } \overline{s}_{(\gamma_1,\gamma_2,...,\gamma_{n+1})}\right) \\
&= \sum_{k=1}^{n+1} (-1)^{k-1} h_{\gamma_1 - 1 + k} \det\left(\left(h_{\gamma_{i+1} - (i+1) + (j + [j\geq k])}\right)_{i,j=1,2,...,n}\right) \\
&\qquad \left(\text{by (13.81.2), applied to } A = \Lambda,\ N = n+1 \text{ and } \beta_{i,j} = h_{\gamma_i - i + j}\right) \\
&= \sum_{k=0}^{n} \underbrace{(-1)^{(k+1)-1}}_{=(-1)^k} \underbrace{h_{\gamma_1 - 1 + (k+1)}}_{\substack{=h_{m+k} \\ (\text{since } \gamma_1 - 1 + (k+1) = \gamma_1 + k = m + k \\ (\text{because } \gamma_1 = m))}} \det\left(\left(\underbrace{h_{\gamma_{i+1} - (i+1) + (j + [j\geq k+1])}}_{\substack{=h_{\alpha_i - (i+1) + (j + [j\geq k+1])} \\ (\text{since } \gamma_{i+1} = \alpha_i)}}\right)_{i,j=1,2,...,n}\right) \\
&\qquad (\text{here, we have substituted } k+1 \text{ for } k \text{ in the sum}) \\
&= \sum_{k=0}^{n} (-1)^k h_{m+k} \det\left(\left(h_{\alpha_i - (i+1) + (j + [j\geq k+1])}\right)_{i,j=1,2,...,n}\right). \qquad (13.81.3)
\end{aligned}$$

Now, let us check that

$$\det\left(\left(h_{\alpha_i - (i+1) + (j + [j\geq k+1])}\right)_{i,j=1,2,...,n}\right) = e_k^{\perp} \overline{s}_{(\alpha_1,\alpha_2,...,\alpha_n)} \qquad \text{for every } k \in \{0, 1, ..., n\}. \tag{13.81.4}$$

Proof of (13.81.4): Let $k \in \{0, 1, ..., n\}$. The partition (1^k) has length $k \leq n$, and thus can be identified with the n-tuple $\left(\underbrace{1, 1, ..., 1}_{k \text{ times}}, \underbrace{0, 0, ..., 0}_{n-k \text{ times}}\right) = (\beta_1, \beta_2, \ldots, \beta_n)$, where we set $\beta_j = \begin{cases} 1, & \text{if } j \leq k; \\ 0, & \text{if } j > k \end{cases} = [j \leq k] = 1 - [j \geq k+1]$ for every $j \in \{1, 2, ..., n\}$. Thus, $s_{(1^k)} = s_{(\beta_1,\beta_2,...,\beta_n)} = \overline{s}_{(\beta_1,\beta_2,...,\beta_n)}$ (by (2.9.1), applied to $\lambda = (\beta_1, \beta_2, \ldots, \beta_n)$). Hence, $e_k = s_{(1^k)} = \overline{s}_{(\beta_1,\beta_2,...,\beta_n)}$, so that

$$\begin{aligned}
e_k^{\perp} \overline{s}_{(\alpha_1,\alpha_2,...,\alpha_n)} &= \overline{s}^{\perp}_{(\beta_1,\beta_2,...,\beta_n)} \overline{s}_{(\alpha_1,\alpha_2,...,\alpha_n)} = \det\left(\left(h_{\alpha_i - \beta_j - i + j}\right)_{i,j=1,2,...,n}\right) \qquad (\text{by (2.9.2)}) \\
&= \det\left(\left(h_{\alpha_i - (1 - [j\geq k+1]) - i + j}\right)_{i,j=1,2,...,n}\right) \qquad \left(\text{since } \beta_j = 1 - [j \geq k+1] \text{ for every } j \in \{1, 2, ..., n\}\right) \\
&= \det\left(\left(h_{\alpha_i - (i+1) + (j + [j\geq k+1])}\right)_{i,j=1,2,...,n}\right)
\end{aligned}$$

(since $\alpha_i - (1 - [j \geq k+1]) - i + j = \alpha_i - (i+1) + (j + [j \geq k+1])$ for all $(i, j) \in \{1, 2, ..., n\}^2$). This proves (13.81.4).

Now, (13.81.3) becomes

$$\overline{s}_{(m,\alpha_1,\alpha_2,\ldots,\alpha_n)} = \sum_{k=0}^{n} (-1)^k h_{m+k} \underbrace{\det\left(\left(h_{\alpha_i-(i+1)+(j+[j\geq k+1])}\right)_{i,j=1,2,\ldots,n}\right)}_{\substack{=e_k^\perp \overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} \\ \text{(by (13.81.4))}}}$$

$$= \sum_{k=0}^{n} (-1)^k h_{m+k} e_k^\perp \overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = \sum_{i=0}^{n} (-1)^i h_{m+i} e_i^\perp \overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} \tag{13.81.5}$$

(here, we renamed the summation index k as i).

But in order to solve Exercise 2.9.1(d), we need to prove a very similar yet different formula:

$$\overline{s}_{(m,\alpha_1,\alpha_2,\ldots,\alpha_n)} = \sum_{i\in\mathbb{N}} (-1)^i h_{m+i} e_i^\perp \overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}. \tag{13.81.6}$$

These two formulas differ in a minor detail: The sum on the right hand side of (13.81.6) runs over all $i \in \mathbb{N}$, whereas the sum on the right hand side of (13.81.5) only runs over $i \in \{0, 1, ..., n\}$. If we can show that these two sums are equal, then it will follow that the equality (13.81.6) that we are proving and the equality (13.81.5) that we have proven are equivalent, and so the former equality must hold, and Exercise 2.9.1(d) will be solved.

So we need to prove that the sum on the right hand side of (13.81.6) and the sum on the right hand side of (13.81.5) are equal. To achieve this, it clearly suffices to show that all addends in which these sums differ are 0. But these addends are the $(-1)^i h_{m+i} e_i^\perp \overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$ for $i \in \mathbb{N}$ satisfying $i > n$. So we need to prove that $(-1)^i h_{m+i} e_i^\perp \overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = 0$ for all $i \in \mathbb{N}$ satisfying $i > n$. Let us do this now.

Let $i \in \mathbb{N}$ be such that $i > n$. We need to show that $(-1)^i h_{m+i} e_i^\perp \overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)} = 0$.

The second statement of Exercise 2.9.1(c) says that the symmetric function $\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$ either is 0 or equals $\pm s_\nu$ for some partition ν having at most n parts. If it is 0, then $(-1)^i h_{m+i} e_i^\perp \underbrace{\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}}_{=0} = 0$ is obvious, and so we are done. Thus, we can WLOG assume that we are in the other case, i.e., the function $\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}$ equals $\pm s_\nu$ for some partition ν having at most n parts. Assume that we are in this case, and consider this ν. Since ν has at most n parts, we have $\ell(\nu) \leq n$. Now, $\ell\left(\left(1^i\right)\right) = i > n \geq \ell(\nu)$, and therefore $\left(1^i\right) \not\subseteq \nu$. But $e_i = s_{(1^i)}$ and thus $e_i^\perp s_\nu = s_{(1^i)}^\perp s_\nu = s_{\nu/(1^i)} = 0$ (because $\left(1^i\right) \not\subseteq \nu$). Now,

$$(-1)^i h_{m+i} e_i^\perp \underbrace{\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_n)}}_{=\pm s_\nu} = \pm (-1)^i h_{m+i} \underbrace{e_i^\perp s_\nu}_{=0} = 0,$$

which concludes our proof. Exercise 2.9.1(d) is thus solved.

(b) Let $n = \ell(\lambda)$. Then, $\lambda = (\lambda_1, \lambda_2, ..., \lambda_n)$, and the equality (2.9.1) yields $s_\lambda = \overline{s}_{(\lambda_1,\lambda_2,\ldots,\lambda_n)}$.

Also, $\ell((m, \lambda_1, \lambda_2, \lambda_3, ...)) = n + 1$, and thus (2.9.1) (applied to $n + 1$ and $(m, \lambda_1, \lambda_2, \lambda_3, ...)$ instead of n and $\lambda = (\lambda_1, \lambda_2, \lambda_3, ...)$) yields

$$s_{(m,\lambda_1,\lambda_2,\lambda_3,\ldots)} = \overline{s}_{(m,\lambda_1,\lambda_2,\ldots,\lambda_n)}.$$

Compared with

$$\sum_{i\in\mathbb{N}} (-1)^i h_{m+i} e_i^\perp \underbrace{s_\lambda}_{=\overline{s}_{(\lambda_1,\lambda_2,\ldots,\lambda_n)}} = \sum_{i\in\mathbb{N}} (-1)^i h_{m+i} e_i^\perp \overline{s}_{(\lambda_1,\lambda_2,\ldots,\lambda_n)}$$
$$= \overline{s}_{(m,\lambda_1,\lambda_2,\ldots,\lambda_n)} \qquad \text{(by (2.9.3), applied to } \alpha_j = \lambda_j\text{)},$$

this yields $\sum_{i\in\mathbb{N}} (-1)^i h_{m+i} e_i^\perp s_\lambda = s_{(m,\lambda_1,\lambda_2,\lambda_3,\ldots)}$. This solves Exercise 2.9.1(b).

(e) This follows by induction over n from Exercise 2.9.1(d). The induction base (the $n = 0$ case) is trivial. For the induction step, we need to prove that

$$\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_{n+1})} = \left(\mathbf{B}_{\alpha_1} \circ \mathbf{B}_{\alpha_2} \circ \cdots \circ \mathbf{B}_{\alpha_{n+1}}\right)(1),$$

assuming that

$$\overline{s}_{(\alpha_2,\alpha_3,\ldots,\alpha_{n+1})} = \left(\mathbf{B}_{\alpha_2} \circ \mathbf{B}_{\alpha_3} \circ \cdots \circ \mathbf{B}_{\alpha_{n+1}}\right)(1). \tag{13.81.7}$$

But this is fairly straightforward: Applying the map $\mathbf{B}_{\alpha_1}$ to (13.81.7), we obtain

$$\mathbf{B}_{\alpha_1}\left(\overline{s}_{(\alpha_2,\alpha_3,\ldots,\alpha_{n+1})}\right)=\mathbf{B}_{\alpha_1}\left(\left(\mathbf{B}_{\alpha_2}\circ\mathbf{B}_{\alpha_3}\circ\cdots\circ\mathbf{B}_{\alpha_{n+1}}\right)(1)\right)=\left(\mathbf{B}_{\alpha_1}\circ\mathbf{B}_{\alpha_2}\circ\cdots\circ\mathbf{B}_{\alpha_{n+1}}\right)(1).$$

Compared with

$$\begin{aligned}\mathbf{B}_{\alpha_1}\left(\overline{s}_{(\alpha_2,\alpha_3,\ldots,\alpha_{n+1})}\right)&=\sum_{i\in\mathbb{N}}(-1)^i h_{\alpha_1+i}e_i^{\perp}\overline{s}_{(\alpha_2,\alpha_3,\ldots,\alpha_{n+1})} && \text{(by the definition of the map } \mathbf{B}_{\alpha_1}\text{)}\\ &=\overline{s}_{(\alpha_1,\alpha_2,\alpha_3,\ldots,\alpha_{n+1})} && \left(\begin{array}{c}\text{by Exercise 2.9.1(d), applied to } \alpha_1 \text{ and}\\ (\alpha_2,\alpha_3,\ldots,\alpha_{n+1}) \text{ instead of } m \text{ and } (\alpha_1,\alpha_2,\ldots,\alpha_n)\end{array}\right)\\ &=\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_{n+1})},\end{aligned}$$

this yields

$$\overline{s}_{(\alpha_1,\alpha_2,\ldots,\alpha_{n+1})}=\left(\mathbf{B}_{\alpha_1}\circ\mathbf{B}_{\alpha_2}\circ\cdots\circ\mathbf{B}_{\alpha_{n+1}}\right)(1),$$

which completes the induction step and thus the proof.

(f) Let $m\in\mathbb{Z}$. Let n be a positive integer. We have $e_0=1$ and thus $e_0^{\perp}=1^{\perp}=\operatorname{id}$ (by Proposition 2.8.2(iii), applied to $A=\Lambda$). Hence, $e_0^{\perp}p_n=\operatorname{id}(p_n)=p_n$.

If i is a positive integer satisfying $i\neq n$, then

$$e_i^{\perp}p_n=0 \tag{13.81.8}$$

(by Exercise 2.8.8(d), applied to $m=i$).

The definition of $\mathbf{B}_m$ yields

$$\begin{aligned}\mathbf{B}_m(p_n)&=\sum_{i\in\mathbb{N}}(-1)^i h_{m+i}e_i^{\perp}p_n\\ &=\underbrace{(-1)^0}_{=1}\underbrace{h_{m+0}}_{=h_m}\underbrace{e_0^{\perp}p_n}_{=p_n}+\sum_{i>0}(-1)^i h_{m+i}e_i^{\perp}p_n\\ &\qquad\text{(here, we have split off the addend for } i=0 \text{ from the sum)}\\ &=h_mp_n+\sum_{i>0}(-1)^i h_{m+i}e_i^{\perp}p_n.\end{aligned}$$

In view of

$$\begin{aligned}&\sum_{i>0}(-1)^i h_{m+i}e_i^{\perp}p_n\\ &=(-1)^n h_{m+n}\underbrace{e_n^{\perp}p_n}_{\substack{=(-1)^{n-1}\\ \text{(by Exercise 2.8.8(c))}}}+\sum_{\substack{i>0;\\ i\neq n}}(-1)^i h_{m+i}\underbrace{e_i^{\perp}p_n}_{\substack{=0\\ \text{(by (13.81.8))}}}\\ &\qquad\left(\begin{array}{c}\text{here, we have split off the addend for } i=n \text{ from the sum,}\\ \text{since } n \text{ is a positive integer}\end{array}\right)\\ &=(-1)^n h_{m+n}(-1)^{n-1}+\underbrace{\sum_{\substack{i>0;\\ i\neq n}}(-1)^i h_{m+i}0}_{=0}=(-1)^n h_{m+n}(-1)^{n-1}=\underbrace{(-1)^n(-1)^{n-1}}_{\substack{=(-1)^{n+(n-1)}=-1\\ \text{(since } n+(n-1)=2n-1\\ \text{is odd)}}}h_{m+n}=-h_{m+n},\end{aligned}$$

this becomes

$$\mathbf{B}_m(p_n)=h_mp_n+\underbrace{\sum_{i>0}(-1)^i h_{m+i}e_i^{\perp}p_n}_{=-h_{m+n}}=h_mp_n+(-h_{m+n})=h_mp_n-h_{m+n}.$$

This solves Exercise 2.9.1(f).

Remark: Our solution to Exercise 2.9.1(d) was modelled after the rough sketch of a solution to Exercise 2.9.1(b) given in [227, §4.20]; but it involved many technicalities which are not necessary if one is only interested in a solution to Exercise 2.9.1(b). (Specifically, if one only wants to solve Exercise 2.9.1(b), one can avoid the use of Exercise 2.9.1(c).)

We solved Exercise 2.9.1(e) using Exercise 2.9.1(d), but of course one can just as well turn this around and solve Exercise 2.9.1(d) using Exercise 2.9.1(e) if one has an independent solution to Exercise 2.9.1(e). Such an independent solution can be extracted from [17, Corollary 3.30] (using the realization that the immaculate creation operators $\mathbb{B}_m$ of [17] are lifts of our Bernstein operators $\mathbf{B}_m$ to NSym).

13.82. **Solution to Exercise 2.9.3.** *Solution to Exercise 2.9.3.* (a) We shall prove a more general result:

> *Claim 1:* Let A be **any** commutative ring. Let $f \in A[[t]]$ be a power series with constant term 1. Then, there is a unique family $(x_n)_{n\geq 1}$ of elements of A such that

$$f = \prod_{n=1}^{\infty} (1 - x_n t^n)^{-1}. \tag{13.82.1}$$

[*Proof of Claim 1:* This family is constructed recursively: If $x_1, x_2, \ldots, x_{k-1}$ have been determined (for some $k \geq 1$), then x_k is obtained by comparing coefficients before t^k in the equation (13.82.1) (the coefficient before t^k on the left hand side is a known constant, whereas the coefficient before t^k on the right hand side can be written in the form $x_k +$ (some polynomial in $x_1, x_2, ..., x_{k-1}$), and thus the equality of these coefficients gives a linear equation in x_k which can be uniquely solved for x_k). The family $(x_n)_{n\geq 1}$ thus constructed satisfies (13.82.1) (because the constant terms on both sides of (13.82.1) are 1, whereas for every $k \geq 1$, the coefficients before t^k on both sides of (13.82.1) are equal due to the construction of x_k). Moreover, it is the only family that satisfies (13.82.1) (since its construction was dictated by (13.82.1)). Thus, Claim 1 is proven.]

Exercise 2.9.3(a) follows by applying Claim 1 to $A = \Lambda$ and $f = H(t)$.

(b) Again, this generalizes: Let us say that a power series $f \in A[[t]]$ over a graded commutative ring A is *equigraded* if, for every $n \in \mathbb{N}$, the coefficient of f before t^n is homogeneous of degree n. Then, if $f \in A[[t]]$ is an equigraded power series with constant term 1, then the unique family $(x_n)_{n\geq 1}$ satisfying (13.82.1) has the property that x_n is homogeneous of degree n for every positive n. This is rather easy to see by induction.

(c) By the definition of the w_n, we have $H(t) = \prod_{n=1}^{\infty} (1 - w_n t^n)^{-1}$. Expanding and comparing coefficients yields precisely $\sum_{\lambda \in \mathrm{Par}_n} w_\lambda = h_n$. [648]

[648] Here are some more details of this argument. From (2.4.1), we have $H(t) = \sum_{n\geq 0} h_n(\mathbf{x}) t^n = \sum_{n\geq 0} h_n t^n$. Thus,

$$\begin{aligned}
\sum_{n\geq 0} h_n t^n = H(t) &= \prod_{n=1}^{\infty} \underbrace{(1 - w_n t^n)^{-1}}_{=\sum_{m\in\mathbb{N}} (w_n t^n)^m} = \prod_{n=1}^{\infty} \sum_{m\in\mathbb{N}} \underbrace{(w_n t^n)^m}_{=w_n^m t^{nm}} \\
&= \prod_{n=1}^{\infty} \sum_{m\in\mathbb{N}} w_n^m t^{nm} = \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \underbrace{\prod_{n=1}^{\infty} w_n^{m_n} t^{nm_n}}_{=\left(\prod_{n=1}^{\infty} w_n^{m_n}\right) t^{1m_1+2m_2+3m_3+\cdots}} \qquad \text{(by the product rule)} \\
&= \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \left(\prod_{n=1}^{\infty} w_n^{m_n} \right) t^{1m_1+2m_2+3m_3+\cdots}. \qquad (13.82.2)
\end{aligned}$$

But every partition λ can be uniquely written in the form $\lambda = (1^{m_1} 2^{m_2} 3^{m_3} \cdots)$ for some weak composition $(m_1, m_2, m_3, \ldots)$. Thus, we can substitute $(1^{m_1} 2^{m_2} 3^{m_3} \cdots)$ for λ in the sum $\sum_{\lambda\in\mathrm{Par}} w_\lambda t^{|\lambda|}$. As a result, we obtain

$$\begin{aligned}
\sum_{\lambda\in\mathrm{Par}} w_\lambda t^{|\lambda|} &= \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \underbrace{w_{(1^{m_1} 2^{m_2} 3^{m_3} \cdots)}}_{\substack{=w_1^{m_1} w_2^{m_2} w_3^{m_3} \cdots \\ \text{(by the definition of } w_{(1^{m_1} 2^{m_2} 3^{m_3} \cdots)})}} \underbrace{t^{|(1^{m_1} 2^{m_2} 3^{m_3} \cdots)|}}_{\substack{=t^{1m_1+2m_2+3m_3+\cdots} \\ \text{(since } |(1^{m_1} 2^{m_2} 3^{m_3} \cdots)| = 1m_1+2m_2+3m_3+\cdots)}} \\
&= \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \underbrace{\left(w_1^{m_1} w_2^{m_2} w_3^{m_3} \cdots\right)}_{=\prod_{n=1}^{\infty} w_n^{m_n}} t^{1m_1+2m_2+3m_3+\cdots} = \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \left(\prod_{n=1}^{\infty} w_n^{m_n} \right) t^{1m_1+2m_2+3m_3+\cdots}.
\end{aligned}$$

Compared with (13.82.2), this yields

$$\sum_{n\geq 0} h_n t^n = \sum_{\lambda\in\mathrm{Par}} w_\lambda t^{|\lambda|} = \sum_{n\geq 0} \underbrace{\sum_{\substack{\lambda\in\mathrm{Par}; \\ |\lambda|=n}}}_{=\sum_{\lambda\in\mathrm{Par}_n}} w_\lambda \underbrace{t^{|\lambda|}}_{\substack{=t^n \\ \text{(since } |\lambda|=n)}} = \sum_{n\geq 0} \sum_{\lambda\in\mathrm{Par}_n} w_\lambda t^n.$$

Comparing coefficients before t^n in this equality of power series, we conclude that $h_n = \sum_{\lambda\in\mathrm{Par}_n} w_\lambda$ for every $n \in \mathbb{N}$, qed.

(d) *First solution to Exercise 2.9.3(d) (sketched).* If $\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(\ell)}$ are finitely many partitions, then we let $\lambda^{(1)} \cup \lambda^{(2)} \cup \cdots \cup \lambda^{(\ell)}$ denote the partition obtained by sorting all the parts of $\lambda^{(1)}, \lambda^{(2)}, ..., \lambda^{(\ell)}$ in decreasing order. For instance, $(3,2,1) \cup (4,2) \cup (5,1) = (5,4,3,2,2,1,1)$. Clearly, if $\lambda^{(1)}, \lambda^{(2)}, ..., \lambda^{(\ell)}$ are finitely many partitions, then

$$w_{\lambda^{(1)}} w_{\lambda^{(2)}} \cdots w_{\lambda^{(\ell)}} = w_{\lambda^{(1)} \cup \lambda^{(2)} \cup \cdots \cup \lambda^{(\ell)}} \tag{13.82.3}$$

(due to the definition of w_λ for a partition λ).

From (c), we know that $h_n = \sum_{\lambda \in \operatorname{Par}_n} w_\lambda$ for every $n \in \mathbb{N}$. In other words,

$$h_n = \sum_{\lambda \vdash n} w_\lambda \qquad \text{for every } n \in \mathbb{N}, \tag{13.82.4}$$

where we are using the notation $\lambda \vdash n$ for $\lambda \in \operatorname{Par}_n$.

Every partition $\mu = (\mu_1, \mu_2, ..., \mu_\ell)$ with $\ell = \ell(\mu)$ satisfies

$$\begin{aligned} h_\mu = h_{\mu_1} h_{\mu_2} \cdots h_{\mu_\ell} &= \prod_{i=1}^{\ell} \underbrace{h_{\mu_i}}_{\substack{= \sum_{\lambda \vdash |\mu_i|} w_\lambda \\ \text{(by (13.82.4), applied to } n = \mu_i)}} \\ &= \prod_{i=1}^{\ell} \left(\sum_{\lambda \vdash |\mu_i|} w_\lambda \right) = \sum_{\substack{(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(\ell)}) \in \operatorname{Par}^\ell; \\ \lambda^{(i)} \vdash \mu_i \text{ for every } i}} \underbrace{w_{\lambda^{(1)}} w_{\lambda^{(2)}} \cdots w_{\lambda^{(\ell)}}}_{\substack{= w_{\lambda^{(1)} \cup \lambda^{(2)} \cup \cdots \cup \lambda^{(\ell)}} \\ \text{(by (13.82.3))}}} \\ &= \sum_{\substack{(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(\ell)}) \in \operatorname{Par}^\ell; \\ \lambda^{(i)} \vdash \mu_i \text{ for every } i}} w_{\lambda^{(1)} \cup \lambda^{(2)} \cup \cdots \cup \lambda^{(\ell)}}. \end{aligned} \tag{13.82.5}$$

Now, let us fix $n \in \mathbb{N}$. We shall prove that $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the $\mathbf{k}$-module Λ_n. First of all, we know that this family $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a family of elements of Λ_n (since for each $\lambda \in \operatorname{Par}_n$, the symmetric function w_λ is homogeneous of degree $|\lambda| = n$).

Now, we define a binary relation $\underset{\text{ref}}{\leq}$ on the set Par_n as follows: If $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$, then we let $\lambda \underset{\text{ref}}{\leq} \mu$ if and only if there exists a tuple $(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(\ell)}) \in \operatorname{Par}^\ell$ satisfying $\ell = \ell(\mu)$, $(\lambda^{(i)} \vdash \mu_i \text{ for every } i)$ and $\lambda^{(1)} \cup \lambda^{(2)} \cup \cdots \cup \lambda^{(\ell)} = \lambda$. The intuitive meaning behind this is the following: We have $\lambda \underset{\text{ref}}{\leq} \mu$ if we can obtain the partition λ by splitting each part μ_i of μ into several smaller parts[649] (which are positive integers summing up to μ_i) and sorting the resulting list into decreasing order. For instance, $(5,3,2,2,2,1) \underset{\text{ref}}{\leq} (6,5,4)$ (because the tuple $(\lambda^{(1)}, \lambda^{(2)}, \lambda^{(3)}) = ((3,2,1), (5), (2,2))$ satisfies $(3,2,1) \vdash 6$, $(5) \vdash 5$ and $(2,2) \vdash 4$ and $(3,2,1) \cup (5) \cup (2,2) = (5,3,2,2,2,1)$).

It is easy to see that the relation $\underset{\text{ref}}{\leq}$ is transitive, antisymmetric and reflexive[650]. Hence, $\underset{\text{ref}}{\leq}$ is the smaller-or-equal relation of a partial order on the set Par_n. Consider Par_n as a poset, equipped with this partial order. (This partial order is called the *refinement order* on partitions[651].)

Now, for any two partitions λ and μ, let $b_{\mu,\lambda}$ denote the number of tuples $(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(\ell)}) \in \operatorname{Par}^\ell$ satisfying $\ell = \ell(\mu)$, $(\lambda^{(i)} \vdash \mu_i \text{ for every } i)$ and $\lambda^{(1)} \cup \lambda^{(2)} \cup \cdots \cup \lambda^{(\ell)} = \lambda$. Then, the formula (13.82.5) rewrites as

$$h_\mu = \sum_{\lambda \in \operatorname{Par}} b_{\mu,\lambda} w_\lambda.$$

[649] We allow the "several smaller parts" to be one single part (namely, μ_i).

[650] In proving these properties (specifically, antisymmetry), it helps to observe the following fact: If $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$ satisfy $\lambda \underset{\text{ref}}{\leq} \mu$, then either $\lambda = \mu$ or $\ell(\lambda) > \ell(\mu)$.

[651] Caution: This order is **not** a restriction of the refinement order on compositions.

Thus, for every $\mu \in \operatorname{Par}_n$, we have

$$h_\mu = \sum_{\lambda \in \operatorname{Par}} b_{\mu,\lambda} w_\lambda = \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| = n}}}_{= \sum_{\lambda \in \operatorname{Par}_n}} b_{\mu,\lambda} w_\lambda + \sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| \neq n}} \underbrace{b_{\mu,\lambda}}_{\substack{=0 \\ \text{(this easily follows} \\ \text{from } |\lambda| \neq n = |\mu|)}} w_\lambda$$
$$= \sum_{\lambda \in \operatorname{Par}_n} b_{\mu,\lambda} w_\lambda + \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}; \\ |\lambda| \neq n}} 0 w_\lambda}_{=0} = \sum_{\lambda \in \operatorname{Par}_n} b_{\mu,\lambda} w_\lambda .$$

Hence, the family $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ expands[652] in the family $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$ through the matrix $(b_{\mu,\lambda})_{(\mu,\lambda) \in \operatorname{Par}_n \times \operatorname{Par}_n}$. But this matrix $(b_{\mu,\lambda})_{(\mu,\lambda) \in \operatorname{Par}_n \times \operatorname{Par}_n}$ is easily seen to be unitriangular (indeed, $b_{\mu,\lambda} = 0$ for any $(\mu, \lambda) \in \operatorname{Par}_n$ which do not satisfy $\lambda \underset{\text{ref}}{\leq} \mu$, and furthermore, every $\lambda \in \operatorname{Par}_n$ satisfies $b_{\lambda,\lambda} = 1$) and therefore invertibly triangular. Hence, the family $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ expands invertibly triangularly in the family $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$. Corollary 11.1.19(e) (applied to Λ_n, Par_n, $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ and $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$) thus shows that the family $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the **k**-module Λ_n if and only if the family $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the **k**-module Λ_n. Hence, the family $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the **k**-module Λ_n (since we know that the family $(h_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the **k**-module Λ_n).

Now, forget that we fixed n. We thus have shown that, for every $n \in \mathbb{N}$, the family $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$ is a basis of the **k**-module Λ_n. Hence, the disjoint union of the families $(w_\lambda)_{\lambda \in \operatorname{Par}_n}$ over all $n \in \mathbb{N}$ is a basis of the direct sum $\bigoplus_{n \in \mathbb{N}} \Lambda_n$. Since the former disjoint union is the family $(w_\lambda)_{\lambda \in \operatorname{Par}}$, whereas the latter direct sum is $\bigoplus_{n \in \mathbb{N}} \Lambda_n = \Lambda$, this result rewrites as follows: The family $(w_\lambda)_{\lambda \in \operatorname{Par}}$ is a basis of the **k**-module Λ. This solves Exercise 2.9.3(d).

[*Remark:* We could have slightly simplified this argument by using a coarser partial order instead of $\underset{\text{ref}}{\leq}$. Namely, we can define a binary relation $\underset{\text{len}}{\leq}$ on the set Par_n as follows: If $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$, then we let $\lambda \underset{\text{len}}{\leq} \mu$ if and only if either $\ell(\lambda) > \ell(\mu)$ or $\lambda = \mu$. Then, clearly, $\underset{\text{len}}{\leq}$ is the smaller-or-equal relation of a partial order on the set Par_n. If we consider Par_n as a poset equipped with this partial order, then the matrix $(b_{\mu,\lambda})_{(\mu,\lambda) \in \operatorname{Par}_n \times \operatorname{Par}_n}$ is still unitriangular, and thus our argument above still works, but we save ourselves the trouble of proving that $\underset{\text{ref}}{\leq}$ is a partial order.]

Second solution to Exercise 2.9.3(d) (sketched). From part (c), we see that h_n can be written as a polynomial in the $w_1, w_2, w_3, \ldots$ for each $n \in \mathbb{N}$. Therefore, $w_1, w_2, w_3, \ldots$ generate Λ as a **k**-algebra (because $h_1, h_2, h_3, \ldots$ generate Λ as a **k**-algebra). In other words, the family $(w_\lambda)_{\lambda \in \operatorname{Par}}$ spans the **k**-module Λ [653]. Recall that $w_\lambda \in \Lambda_{|\lambda|}$ for each $\lambda \in \operatorname{Par}$. In other words, w_λ is an element of $\Lambda_{|\lambda|}$ for each partition λ. Hence, Exercise 2.5.19 (applied to $v_\lambda = w_\lambda$) yields that the family $(w_\lambda)_{\lambda \in \operatorname{Par}}$ is a graded basis of the graded **k**-module Λ. Thus, in particular, this family $(w_\lambda)_{\lambda \in \operatorname{Par}}$ is a basis of the **k**-module Λ. This solves Exercise 2.9.3(d) again.

[652] Here, we are using the terminology of Section 11.1.

[653] We have used Exercise 2.2.14(b) (applied to w_m and w_λ instead of v_m and v_λ) here. Alternatively, this can also be seen using (13.82.5).

(e) By the definition of the w_n, we have $H(t) = \prod_{n=1}^{\infty} (1 - w_n t^n)^{-1}$. Hence,[654]

$$\frac{d}{dt}(\log H(t)) = \frac{d}{dt}\left(\log \prod_{n=1}^{\infty} (1 - w_n t^n)^{-1}\right) = \frac{d}{dt}\sum_{n=1}^{\infty} \log\left((1 - w_n t^n)^{-1}\right)$$
$$= \sum_{n=1}^{\infty} \underbrace{\frac{d}{dt}\log\left((1 - w_n t^n)^{-1}\right)}_{=\dfrac{n w_n t^{n-1}}{1 - w_n t^n}} = \sum_{n=1}^{\infty} \frac{n w_n t^{n-1}}{1 - w_n t^n}.$$

Compared with

$$\frac{d}{dt}(\log H(t)) = \frac{H'(t)}{H(t)} = \sum_{m \geq 0} p_{m+1} t^m \qquad \text{(by Exercise 2.5.21)},$$

this yields

$$\sum_{m \geq 0} p_{m+1} t^m = \sum_{n=1}^{\infty} \frac{n w_n t^{n-1}}{1 - w_n t^n}.$$

Multiplying this by t, we obtain

$$\sum_{m \geq 0} p_{m+1} t^{m+1} = \sum_{n=1}^{\infty} \underbrace{\frac{n w_n t^n}{1 - w_n t^n}}_{= n \sum_{k=1}^{\infty} w_n^k t^{nk}} = \sum_{n=1}^{\infty} \sum_{k=1}^{\infty} n w_n^k t^{nk}$$
$$= \sum_{m=1}^{\infty} \sum_{d \mid m} d w_d^{m/d} t^m = \sum_{n=1}^{\infty} \sum_{d \mid n} d w_d^{n/d} t^n,$$

so that $\sum_{n=1}^{\infty} \sum_{d \mid n} d w_d^{n/d} t^n = \sum_{m \geq 0} p_{m+1} t^{m+1} = \sum_{n \geq 1} p_n t^n$. Comparing coefficients yields the claim of part (e).

[654] We will be using logarithms here, so prima facie our argument only works when the base ring $\mathbf{k}$ is a $\mathbb{Q}$-algebra. However, it is easy to see that our argument can easily be adapted to work in the general case as well. For example, one can argue that even if the power series $\log t$ is not defined if $\mathbf{k}$ is not a $\mathbb{Q}$-algebra, the notion of the logarithmic derivative $\frac{d}{dt}(\log Q)$ is well-defined for every $\mathbf{k}$ whenever $Q \in \mathbf{k}[[t]]$ is a power series with constant term 1 (for example, one could use the formula $\frac{d}{dt}(\log Q) = \frac{Q'(t)}{Q(t)}$ as the *definition* of the logarithmic derivative) and still has the familiar property of turning products into sums in this generality. See the solution to Exercise 2.5.21 for details about this.

(f) This is done in [55]. For the sake of completeness: First, let $n \geq k \geq 2$. Then, every $i \in \{2, 3, ..., k-1\}$ satisfies $f_{i,i} = \sum_{\substack{\lambda \in \operatorname{Par}_i, \\ \min \lambda \geq i}} w_\lambda = w_{(i)} = w_i$. Thus,

$$\begin{aligned}
\sum_{i=2}^{k-1} \underbrace{f_{i,i}}_{=w_i} \underbrace{f_{n-i,i}}_{=\sum_{\substack{\lambda \in \operatorname{Par}_{n-i}, \\ \min \lambda \geq i}} w_\lambda} &= \sum_{i=2}^{k-1} \underbrace{w_i \sum_{\substack{\lambda \in \operatorname{Par}_{n-i}, \\ \min \lambda \geq i}} w_\lambda}_{= \sum_{\substack{\lambda \in \operatorname{Par}_{n-i}, \\ \min \lambda \geq i}} w_\lambda w_i = \sum_{\substack{\lambda \in \operatorname{Par}_{n}, \\ \min \lambda = i}} w_\lambda} = \sum_{i=2}^{k-1} \sum_{\substack{\lambda \in \operatorname{Par}_{n}, \\ \min \lambda = i}} w_\lambda \\
&= \sum_{\substack{\lambda \in \operatorname{Par}_{n}, \\ 2 \leq \min \lambda < k}} w_\lambda = \underbrace{\sum_{\lambda \in \operatorname{Par}_n} w_\lambda}_{\substack{=h_n \\ \text{(by part (c))}}} - \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}_{n}, \\ \min \lambda = 1}} w_\lambda}_{=w_1 \sum_{\lambda \in \operatorname{Par}_{n-1}} w_\lambda} - \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}_{n}, \\ \min \lambda \geq k}} w_\lambda}_{=f_{n,k}} \\
&= h_n - \underbrace{w_1}_{=h_1} \underbrace{\sum_{\lambda \in \operatorname{Par}_{n-1}} w_\lambda}_{\substack{=h_{n-1} \\ \text{(by part (c))}}} - f_{n,k} \\
&= \underbrace{h_n}_{=s_{(n)}} - h_1 \underbrace{h_{n-1}}_{=s_{(n-1)}} - f_{n,k} \\
&= s_{(n)} - \underbrace{h_1 s_{(n-1)}}_{\substack{=s_{(n)} + s_{(n-1,1)} \\ \text{(by the Pieri rule)}}} - f_{n,k} \\
&= -s_{(n-1,1)} - f_{n,k};
\end{aligned}$$

in other words,

$$-f_{n,k} = s_{(n-1,1)} + \sum_{i=2}^{k-1} f_{i,i} f_{n-i,i}.$$

From this, we can conclude inductively that $-f_{n,k}$ is a sum of Schur functions for every $n \in \mathbb{N}$ and $k \geq 2$ (in fact, the trivial cases with $n < 2$ have to be taken as induction base). Since $f_{n,n} = \sum_{\substack{\lambda \in \operatorname{Par}_n, \\ \min \lambda \geq n}} w_\lambda = w_{(n)} = w_n$, this yields that $-w_n$ is a sum of Schur functions for every $n \geq 2$.

(g) Every partition λ can be uniquely written in the form $\lambda = (1^{m_1} 2^{m_2} 3^{m_3} \cdots)$ for some weak composition $(m_1, m_2, m_3, \ldots)$. Thus,

$$\begin{aligned}
\sum_{\lambda \in \operatorname{Par}} w_\lambda(\mathbf{x}) r_\lambda(\mathbf{y}) &= \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \underbrace{w_{(1^{m_1}2^{m_2}3^{m_3}\cdots)}(\mathbf{x})}_{\substack{=\prod_{i\geq 1}(w_i(\mathbf{x}))^{m_i} \\ \text{(by the definition of } w_\lambda\text{)}}} \underbrace{r_{(1^{m_1}2^{m_2}3^{m_3}\cdots)}(\mathbf{y})}_{\substack{=\prod_{i\geq 1} h_{m_i}\left(y_1^i, y_2^i, y_3^i, \ldots\right) \\ \text{(by the definition of } r_\lambda\text{)}}} \\
&= \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \left(\prod_{i \geq 1} (w_i(\mathbf{x}))^{m_i} \right) \left(\prod_{i \geq 1} h_{m_i}\left(y_1^i, y_2^i, y_3^i, \ldots\right) \right) \\
&= \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \prod_{i \geq 1} (w_i(\mathbf{x}))^{m_i} h_{m_i}\left(y_1^i, y_2^i, y_3^i, \ldots\right) \\
&= \sum_{\substack{(m_1,m_2,m_3,\ldots) \\ \text{weak composition}}} \prod_{i \geq 1} h_{m_i}\left(y_1^i, y_2^i, y_3^i, \ldots\right) (w_i(\mathbf{x}))^{m_i} \\
&= \prod_{i \geq 1} \underbrace{\sum_{m \in \mathbb{N}} h_m\left(y_1^i, y_2^i, y_3^i, \ldots\right) (w_i(\mathbf{x}))^m}_{\substack{=\prod_{j\geq 1}\left(1 - y_j^i w_i(\mathbf{x})\right)^{-1} \\ \text{(by (2.2.18), upon substitution of } (y_1,y_2,y_3,\ldots) \text{ and } w_i(\mathbf{x}) \text{ for } \mathbf{x} \text{ and } t\text{)}}} \\
&= \prod_{i \geq 1} \prod_{j \geq 1} \left(1 - y_j^i w_i(\mathbf{x})\right)^{-1} = \prod_{j \geq 1} \underbrace{\prod_{i \geq 1} \left(1 - y_j^i w_i(\mathbf{x})\right)^{-1}}_{\substack{=\prod_{n\geq 1}\left(1 - y_j^n w_n(\mathbf{x})\right)^{-1} \\ =\prod_{n=1}^{\infty}\left(1 - w_n(\mathbf{x}) y_j^n\right)^{-1} \\ =H(y_j) \\ \text{(since } \prod_{n=1}^{\infty}(1-w_n t^n)^{-1} = H(t)\text{)}}} \\
&= \prod_{j \geq 1} \underbrace{H(y_j)}_{=\prod_{i=1}^{\infty}(1 - x_i y_j)^{-1}} = \prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1}.
\end{aligned}$$

This proves (g).

(h) For every partition λ, both symmetric functions w_λ and r_λ are homogeneous of degree $|\lambda|$. (In fact, for w_λ this follows from Exercise 2.9.3(c), whereas for r_λ this is easily derived from the definition.)

From Exercise 2.9.3(g), we obtain $\sum_{\lambda \in \operatorname{Par}} w_\lambda(\mathbf{x}) r_\lambda(\mathbf{y}) = \prod_{i,j=1}^{\infty} (1 - x_i y_j)^{-1} = \sum_{\lambda \in \operatorname{Par}} s_\lambda(\mathbf{x}) s_\lambda(\mathbf{y})$ (by (2.5.1)). Thus, we can apply Exercise 2.5.20(a) to $u_\lambda = w_\lambda$ and $v_\lambda = r_\lambda$. As a result, we obtain that $(w_\lambda)_{\lambda \in \operatorname{Par}}$ and $(r_\lambda)_{\lambda \in \operatorname{Par}}$ are $\mathbf{k}$-bases of Λ, and actually are dual bases with respect to the Hall inner product on Λ. Thus we have solved Exercise 2.9.3(h), but also given another proof of Exercise 2.9.3(d) in the process (because we have shown once again that $(w_\lambda)_{\lambda \in \operatorname{Par}}$ is a $\mathbf{k}$-basis of Λ).

13.83. **Solution to Exercise 2.9.4.** *Solution to Exercise 2.9.4.* (a) Let $f \in \Lambda$.

Recall the following fundamental fact from linear algebra: If $\mathbf{k}$ is a commutative ring, if A is a $\mathbf{k}$-module, if $(\cdot, \cdot) : A \times A \to \mathbf{k}$ is a symmetric $\mathbf{k}$-bilinear form on A, and if $(u_\lambda)_{\lambda \in L}$ and $(v_\lambda)_{\lambda \in L}$ are two $\mathbf{k}$-bases of A which are dual to each other with respect to the form $(\cdot, \cdot)$ (where L is some indexing set), then every $a \in A$ satisfies

$$a = \sum_{\lambda \in L} (u_\lambda, a) v_\lambda. \tag{13.83.1}$$

We can apply this fact to $\mathbf{k} = \mathbb{Q}$, $A = \Lambda_{\mathbb{Q}}$, $L = \operatorname{Par}$, $(u_\lambda)_{\lambda \in L} = (p_\lambda)_{\lambda \in \operatorname{Par}}$, $(v_\lambda)_{\lambda \in L} = \left(z_\lambda^{-1} p_\lambda\right)_{\lambda \in \operatorname{Par}}$ and $a = f$ (because the bases $(p_\lambda)_{\lambda \in \operatorname{Par}}$ and $\left(z_\lambda^{-1} p_\lambda\right)_{\lambda \in \operatorname{Par}}$ of $\Lambda_{\mathbb{Q}}$ are dual to each other with respect to the Hall inner product $(\cdot,\cdot)$, as Corollary 2.5.17(b) shows). As a result, we obtain

$$f = \sum_{\lambda\in\operatorname{Par}} (p_\lambda, f)\, z_\lambda^{-1} p_\lambda .$$

Hence,

$$\begin{aligned} Z(f) &= Z\left(\sum_{\lambda\in\operatorname{Par}} (p_\lambda, f)\, z_\lambda^{-1} p_\lambda\right) = \sum_{\lambda\in\operatorname{Par}} (p_\lambda, f)\, z_\lambda^{-1} \underbrace{Z(p_\lambda)}_{=z_\lambda p_\lambda} = \sum_{\lambda\in\operatorname{Par}} (p_\lambda, f)\, z_\lambda^{-1} z_\lambda p_\lambda \\ &= \sum_{\lambda\in\operatorname{Par}} \underbrace{(p_\lambda, f)}_{\substack{\in\mathbb{Z} \\ (\text{since } f\in\Lambda \text{ and } p_\lambda\in\Lambda)}} p_\lambda \in \sum_{\lambda\in\operatorname{Par}} \mathbb{Z} p_\lambda \subset \Lambda . \end{aligned}$$

Since we have proven this for every $f \in \Lambda$, we thus have shown that $Z(\Lambda) \subset \Lambda$. This solves Exercise 2.9.4(a).

(b) *First solution of Exercise 2.9.4(b):* Consider two variable sets $\mathbf{x} = (x_1, x_2, x_3, ...)$ and $\mathbf{y} = (y_1, y_2, y_3, ...)$. Let $\mathbf{xy}$ denote the variable set

$$\begin{aligned} (x_i y_j)_{(i,j)\in\{1,2,3,...\}^2} = (&x_1y_1, x_1y_2, x_1y_3, ..., \\ &x_2y_1, x_2y_2, x_2y_3, ..., \\ &x_3y_1, x_3y_2, x_3y_3, ..., \\ &...) . \end{aligned}$$

Now, we claim that for every $f \in \Lambda_{\mathbb{Q}}$,

$$\text{there is a well-defined element } f(\mathbf{xy}) := f\left((x_iy_j)_{(i,j)\in\{1,2,3,...\}^2}\right) \text{ of } \mathbb{Q}[[\mathbf{x},\mathbf{y}]] . \tag{13.83.2}$$

This claim (13.83.2) is not obvious! For example, there is generally no well-defined element $f\left((x_i+y_j)_{(i,j)\in\{1,2,3,...\}^2}\right)$, because e.g. in the case of $f = e_1$ we would have $e_1\left((x_i+y_j)_{(i,j)\in\{1,2,3,...\}^2}\right) = \sum_{(i,j)\in\{1,2,3,...\}^2} (x_i+y_j)$, which is a sum containing infinitely many x_1's. So there is some subtlety which allows us to make sense of $f\left((x_iy_j)_{(i,j)\in\{1,2,3,...\}^2}\right)$ but not of $f\left((x_i+y_j)_{(i,j)\in\{1,2,3,...\}^2}\right)$.

Here is a sketch of a *proof of (13.83.2):* Consider a new variable set $\mathbf{s} := (s_{i,j})_{(i,j)\in\{1,2,3,...\}^2}$ whose variables are indexed by **pairs** of positive integers. This variable set $\mathbf{s}$ is still countably infinite, and so there is an isomorphism $\Lambda_{\mathbb{Q}} = \Lambda_{\mathbb{Q}}(\mathbf{x}) \to \Lambda_{\mathbb{Q}}(\mathbf{s})$. On the other hand, we can consider the ring $\mathbb{Q}[[\mathbf{s}]]$ of formal power series in the variables from the set $\mathbf{s}$, and then we have $\Lambda_{\mathbb{Q}}(\mathbf{s}) \subset \mathbb{Q}[[\mathbf{s}]]$. It is easy to see that $g\left((x_iy_j)_{(i,j)\in\{1,2,3,...\}^2}\right)$ is a well-defined element of $\mathbb{Q}[[\mathbf{x},\mathbf{y}]]$ for every $g \in \mathbb{Q}[[\mathbf{s}]]$ [655]. Hence, for every $f \in \Lambda_{\mathbb{Q}}$, there is a well-defined element $f(\mathbf{xy}) := f\left((x_iy_j)_{(i,j)\in\{1,2,3,...\}^2}\right)$ of $\mathbb{Q}[[\mathbf{x},\mathbf{y}]]$ (because we can regard f as an element of $\Lambda_{\mathbb{Q}}(\mathbf{s}) \subset \mathbb{Q}[[\mathbf{s}]]$ by means of the isomorphism $\Lambda_{\mathbb{Q}} = \Lambda_{\mathbb{Q}}(\mathbf{x}) \to \Lambda_{\mathbb{Q}}(\mathbf{s})$). This proves (13.83.2).

[655] *Proof.* Let $g \in \mathbb{Q}[[\mathbf{s}]]$. When $(x_iy_j)_{(i,j)\in\{1,2,3,...\}^2}$ is substituted for $(s_{i,j})_{(i,j)\in\{1,2,3,...\}^2}$ in the power series $g \in \mathbb{Q}[[\mathbf{s}]]$, every monomial in the variables $\mathbf{s}$ turns into a monomial in the variables $(\mathbf{x},\mathbf{y})$, and **any given monomial in $(\mathbf{x},\mathbf{y})$ can only be obtained (this way) from finitely many monomials in $\mathbf{s}$** (indeed, a given monomial $\mathbf{x}^\alpha\mathbf{y}^\beta$ in $(\mathbf{x},\mathbf{y})$ can only be obtained from monomials $\prod_{i,j=1,2,3,...} s_{i,j}^{\gamma_{i,j}}$ whose exponents $\gamma_{i,j}$ satisfy the equations

$$\begin{aligned} \sum_{i=1}^{\infty} \gamma_{i,j} &= \beta_j && \text{for all } j \in \{1,2,3,...\} ; \\ \sum_{j=1}^{\infty} \gamma_{i,j} &= \alpha_i && \text{for all } i \in \{1,2,3,...\} ; \end{aligned}$$

but it is easy to see that these equations leave only finitely many possibilities for the monomial $\prod_{i,j=1,2,3,...} s_{i,j}^{\gamma_{i,j}}$). Hence, the substitution yields an infinite sum of monomials in which every monomial occurs **only finitely often**; therefore, this sum converges. This shows that $g\left((x_iy_j)_{(i,j)\in\{1,2,3,...\}^2}\right)$ is a well-defined element of $\mathbb{Q}[[\mathbf{x},\mathbf{y}]]$.

Due to (13.83.2), we can define a map

$$\begin{aligned}\widetilde{\Delta}_\times : \Lambda_{\mathbb{Q}} &\to \mathbb{Q}[[\mathbf{x},\mathbf{y}]],\\ f &\mapsto f(\mathbf{xy}) = f\left((x_i y_j)_{(i,j)\in\{1,2,3,\ldots\}^2}\right).\end{aligned}$$

This map $\widetilde{\Delta}_\times$ is an evaluation map (in an appropriate sense), and thus a $\mathbb{Q}$-algebra homomorphism. It is also clear that $\widetilde{\Delta}_\times(\Lambda) \subset \mathbb{Z}[[\mathbf{x},\mathbf{y}]]$ (where $\mathbb{Z}[[\mathbf{x},\mathbf{y}]]$ is regarded as a subring of $\mathbb{Q}[[\mathbf{x},\mathbf{y}]]$ in the obvious way).

Now, recall the $\mathbb{Q}$-algebra isomorphism $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to R_{\mathbb{Q}}(\mathbf{x},\mathbf{y})^{\mathfrak{S}_{(\infty)}\times\mathfrak{S}_{(\infty)}}$ constructed in (2.1.3) (applied to $\mathbf{k} = \mathbb{Q}$). This entails a $\mathbb{Q}$-algebra injection $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to \mathbb{Q}[[\mathbf{x},\mathbf{y}]]$ (since $R_{\mathbb{Q}}(\mathbf{x},\mathbf{y})^{\mathfrak{S}_{(\infty)}\times\mathfrak{S}_{(\infty)}} \subset R_{\mathbb{Q}}(\mathbf{x},\mathbf{y}) \subset \mathbb{Q}[[\mathbf{x},\mathbf{y}]]$). Denote this injection by ι.

We shall now show that

$$\iota \circ \Delta_\times = \widetilde{\Delta}_\times. \tag{13.83.3}$$

Proof of (13.83.3): Indeed, (13.83.3) is an equality between $\mathbb{Q}$-algebra homomorphisms (since $\widetilde{\Delta}_\times$, ι and $\Delta_\times$ are $\mathbb{Q}$-algebra homomorphisms), and thus, in order to prove it, we only need to check that it holds on a generating set of the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$. We do this on the generating set $(p_n)_{n\geq 1}$, by noticing that every $n \geq 1$ satisfies

$$\begin{aligned}(\iota \circ \Delta_\times)(p_n) &= \iota\Bigg(\underbrace{\Delta_\times(p_n)}_{=p_n\otimes p_n}\Bigg) = \iota(p_n \otimes p_n) = \underbrace{p_n(\mathbf{x})}_{=\sum_{i\geq 1} x_i^n} \underbrace{p_n(\mathbf{y})}_{=\sum_{j\geq 1} y_j^n} \qquad \text{(by the definition of } \iota)\\ &= \left(\sum_{i\geq 1} x_i^n\right)\left(\sum_{j\geq 1} y_j^n\right) = \underbrace{\sum_{i\geq 1}\sum_{j\geq 1}}_{=\sum_{(i,j)\in\{1,2,3,\ldots\}^2}} \underbrace{x_i^n y_j^n}_{=(x_i y_j)^n} = \sum_{(i,j)\in\{1,2,3,\ldots\}^2} (x_i y_j)^n\\ &= p_n\Bigg(\underbrace{(x_i y_j)_{(i,j)\in\{1,2,3,\ldots\}^2}}_{=\mathbf{xy}}\Bigg) = p_n(\mathbf{xy}) = \widetilde{\Delta}_\times(p_n)\\ &\qquad \left(\text{since } \widetilde{\Delta}_\times(p_n) = p_n(\mathbf{xy}) \text{ (by the definition of } \widetilde{\Delta}_\times(p_n))\right).\end{aligned}$$

So (13.83.3) is proven.

From (13.83.3), we obtain $\underbrace{(\iota \circ \Delta_\times)}_{=\widetilde{\Delta}_\times}(\Lambda) = \widetilde{\Delta}_\times(\Lambda) \subset \mathbb{Z}[[\mathbf{x},\mathbf{y}]]$, so that $\iota(\Delta_\times(\Lambda)) = (\iota \circ \Delta_\times)(\Lambda) \subset \mathbb{Z}[[\mathbf{x},\mathbf{y}]]$ and thus $\Delta_\times(\Lambda) \subset \iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]])$.

But it so happens that $\iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]]) = \Lambda \otimes_{\mathbb{Z}} \Lambda$ [656]. Hence, $\Delta_\times(\Lambda) \subset \iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]]) = \Lambda \otimes_{\mathbb{Z}} \Lambda$. This solves Exercise 2.9.4(b).

[656] *Proof.* It is clear that $\iota(\Lambda \otimes_{\mathbb{Z}} \Lambda) \subset \mathbb{Z}[[\mathbf{x},\mathbf{y}]]$, so that $\Lambda \otimes_{\mathbb{Z}} \Lambda \subset \iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]])$. We are now going to prove the reverse inclusion $\iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]]) \subset \Lambda \otimes_{\mathbb{Z}} \Lambda$.

Indeed, let $p \in \iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]])$. Then, p is an element of $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ satisfying $\iota(p) \in \mathbb{Z}[[\mathbf{x},\mathbf{y}]]$. All coefficients of the power series $\iota(p)$ are integers (since $\iota(p) \in \mathbb{Z}[[\mathbf{x},\mathbf{y}]]$).

We can write p in the form $p = \sum_{(\lambda,\mu)\in\operatorname{Par}\times\operatorname{Par}} \rho_{\lambda,\mu} m_\lambda \otimes m_\mu$ with $\rho_{\lambda,\mu}$ being elements of $\mathbb{Q}$ (because $(m_\lambda \otimes m_\mu)_{(\lambda,\mu)\in\operatorname{Par}\times\operatorname{Par}}$ is a $\mathbb{Q}$-basis of $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ (since $(m_\lambda)_{\lambda\in\operatorname{Par}}$ is a $\mathbb{Q}$-basis of $\Lambda_{\mathbb{Q}}$)). Consider these elements $\rho_{\lambda,\mu}$. Since $p = \sum_{(\lambda,\mu)\in\operatorname{Par}\times\operatorname{Par}} \rho_{\lambda,\mu} m_\lambda \otimes m_\mu$, we have $\iota(p) = \sum_{(\lambda,\mu)\in\operatorname{Par}\times\operatorname{Par}} \rho_{\lambda,\mu} m_\lambda(\mathbf{x}) m_\mu(\mathbf{y})$ (by the definition of ι). Therefore, for every $(\alpha,\beta) \in \operatorname{Par}\times\operatorname{Par}$, the rational number $\rho_{\alpha,\beta}$ is the coefficient of the power series $\iota(p)$ before the monomial $\mathbf{x}^\alpha \mathbf{y}^\beta$ (since there is clearly only one term in the sum $\sum_{(\lambda,\mu)\in\operatorname{Par}\times\operatorname{Par}} \rho_{\lambda,\mu} m_\lambda(\mathbf{x}) m_\mu(\mathbf{y})$ contributing to this coefficient, namely the term for $(\lambda,\mu) = (\alpha,\beta)$, and this term contributes $\rho_{\alpha,\beta}$). In particular, this number $\rho_{\alpha,\beta}$ must be an integer (since all coefficients of the power series $\iota(p)$ are integers). So we have shown that $\rho_{\alpha,\beta}$ is an integer for every $(\alpha,\beta) \in \operatorname{Par}\times\operatorname{Par}$. In other words, $\rho_{\lambda,\mu}$ is an integer for every $(\lambda,\mu) \in \operatorname{Par}\times\operatorname{Par}$. Now, $p = \sum_{(\lambda,\mu)\in\operatorname{Par}\times\operatorname{Par}} \underbrace{\rho_{\lambda,\mu}}_{\text{an integer}} m_\lambda \otimes m_\mu \in \Lambda \otimes_{\mathbb{Z}} \Lambda$.

Forget now that we fixed p. We thus have shown that $p \in \Lambda \otimes_{\mathbb{Z}} \Lambda$ for every $p \in \iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]])$. In other words, $\iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]]) \subset \Lambda \otimes_{\mathbb{Z}} \Lambda$. Combined with $\Lambda \otimes_{\mathbb{Z}} \Lambda \subset \iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]])$, this yields $\iota^{-1}(\mathbb{Z}[[\mathbf{x},\mathbf{y}]]) = \Lambda \otimes_{\mathbb{Z}} \Lambda$, qed.

Second solution of Exercise 2.9.4(b): The following solution of Exercise 2.9.4(b) is a variation on the First one given above. It avoids the use of (13.83.2) in favor of working with finite variable sets. (This has the advantage that we no longer need to bother about technicalities; but more importantly, this approach will be very useful in solving Exercise 2.9.4(f) later on.)

Let $N \in \mathbb{N}$ be arbitrary. We define a $\mathbb{Q}$-linear map

$$\begin{aligned} \mathcal{E}_N : \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} &\to \mathbb{Q}\left[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N\right], \\ f \otimes g &\mapsto f\left(x_1, x_2, ..., x_N\right) g\left(y_1, y_2, ..., y_N\right). \end{aligned}$$

This is well-defined because $f\left(x_1, x_2, ..., x_N\right) \in \mathbb{Q}\left[x_1, x_2, ..., x_N\right]$ and $g\left(y_1, y_2, ..., y_N\right) \in \mathbb{Q}\left[y_1, y_2, ..., y_N\right]$ are well-defined polynomials for every $f \in \Lambda_{\mathbb{Q}}$ and $g \in \Lambda_{\mathbb{Q}}$ (by Exercise 2.1.2) and depend linearly on f and g, respectively. It is easy to see that the map $\mathcal{E}_N$ is a $\mathbb{Q}$-algebra homomorphism.

Next, we define a map

$$\begin{aligned} \mathcal{K}_N : \Lambda_{\mathbb{Q}} &\to \mathbb{Q}\left[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N\right], \\ f &\mapsto f\left(\left(x_i y_j\right)_{(i,j)\in\{1,2,...,N\}^2}\right). \end{aligned}$$

Here, $f\left(\left(x_i y_j\right)_{(i,j)\in\{1,2,...,N\}^2}\right)$ is defined as follows: Let $\left(u_1, u_2, ..., u_{N^2}\right)$ be a list of all N^2 elements of the family $\left(x_i y_j\right)_{(i,j)\in\{1,2,...,N\}^2}$ in any arbitrary order, and set $f\left(\left(x_i y_j\right)_{(i,j)\in\{1,2,...,N\}^2}\right) = f\left(u_1, u_2, ..., u_{N^2}\right)$. (The result does not depend on the order chosen, because f is symmetric.)

Again, $\mathcal{K}_N$ is a $\mathbb{Q}$-algebra homomorphism (since $\mathcal{K}_N$ is an evaluation map in an appropriate sense).

We now claim that

$$\mathcal{E}_N \circ \Delta_\times = \mathcal{K}_N. \tag{13.83.4}$$

Proof of (13.83.4): The equality (13.83.4) is an equality between $\mathbb{Q}$-algebra homomorphisms (since $\mathcal{K}_N$, $\mathcal{E}_N$ and $\Delta_\times$ are $\mathbb{Q}$-algebra homomorphisms), and thus, in order to prove it, we only need to check that it holds on a generating set of the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$. We do this on the generating set $\left(p_n\right)_{n\geq 1}$, by noticing that every $n \geq 1$ satisfies

$$\begin{aligned} \left(\mathcal{E}_N \circ \Delta_\times\right)\left(p_n\right) &= \mathcal{E}_N\left(\underbrace{\Delta_\times\left(p_n\right)}_{=p_n\otimes p_n}\right) = \mathcal{E}_N\left(p_n \otimes p_n\right) \\ &= \underbrace{p_n\left(x_1, x_2, ..., x_N\right)}_{=\sum_{i=1}^N x_i^n} \underbrace{p_n\left(y_1, y_2, ..., y_N\right)}_{=\sum_{j=1}^N y_j^n} \qquad \text{(by the definition of } \mathcal{E}_N\text{)} \\ &= \left(\sum_{i=1}^N x_i^n\right)\left(\sum_{j=1}^N y_j^n\right) = \underbrace{\sum_{i=1}^N \sum_{j=1}^N}_{=\sum_{(i,j)\in\{1,2,...,N\}^2}} \underbrace{x_i^n y_j^n}_{=(x_i y_j)^n} = \sum_{(i,j)\in\{1,2,...,N\}^2} \left(x_i y_j\right)^n \\ &= p_n\left(\left(x_i y_j\right)_{(i,j)\in\{1,2,...,N\}^2}\right) = \mathcal{K}_N\left(p_n\right) \\ &\qquad \left(\text{since } \mathcal{K}_N\left(p_n\right) = p_n\left(\left(x_i y_j\right)_{(i,j)\in\{1,2,...,N\}^2}\right) \text{ (by the definition of } \mathcal{K}_N\left(p_n\right)\text{)}\right). \end{aligned}$$

This proves (13.83.4).

Now,

$$\mathcal{E}_N\left(\Delta_\times\left(\Lambda\right)\right) = \left(\underbrace{\mathcal{E}_N \circ \Delta_\times}_{\substack{=\mathcal{K}_N \\ \text{(by (13.83.4))}}}\right)\left(\Lambda\right) = \mathcal{K}_N\left(\Lambda\right) \subset \mathbb{Z}\left[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N\right]$$

(the latter inclusion is evident from the definition of $\mathcal{K}_N$). Hence, every $p \in \Delta_\times\left(\Lambda\right)$ satisfies

$$\mathcal{E}_N\left(p\right) \in \mathcal{E}_N\left(\Delta_\times\left(\Lambda\right)\right) = \mathbb{Z}\left[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N\right]. \tag{13.83.5}$$

Now, forget that we fixed N. We thus have defined a $\mathbb{Q}$-algebra homomorphism $\mathcal{E}_N : \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to \mathbb{Q}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N]$ for every $N \in \mathbb{N}$, and we have shown that every $p \in \Delta_\times(\Lambda)$ satisfies (13.83.5) for every $N \in \mathbb{N}$.

Now, we are going to show that

$$\left(\begin{array}{c}\text{if some } p \in \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \text{ satisfies} \\ \left(\mathcal{E}_N(p) \in \mathbb{Z}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N] \text{ for every } N \in \mathbb{N}\right), \\ \text{then } p \in \Lambda \otimes_{\mathbb{Z}} \Lambda\end{array}\right) \tag{13.83.6}$$

Proof of (13.83.6): Let $p \in \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ be such that

$$\left(\mathcal{E}_N(p) \in \mathbb{Z}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N] \text{ for every } N \in \mathbb{N}\right). \tag{13.83.7}$$

We can write p in the form $p = \sum_{(\lambda,\mu)\in\mathrm{Par}\times\mathrm{Par}} \rho_{\lambda,\mu} m_\lambda \otimes m_\mu$ with $\rho_{\lambda,\mu}$ being elements of $\mathbb{Q}$ (because $(m_\lambda \otimes m_\mu)_{(\lambda,\mu)\in\mathrm{Par}\times\mathrm{Par}}$ is a $\mathbb{Q}$-basis of $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ (since $(m_\lambda)_{\lambda\in\mathrm{Par}}$ is a $\mathbb{Q}$-basis of $\Lambda_{\mathbb{Q}}$)). Consider these elements $\rho_{\lambda,\mu}$.

Now, let $(\alpha, \beta) \in \mathrm{Par} \times \mathrm{Par}$ be arbitrary. Choose some $N \in \mathbb{N}$ satisfying $N \geq \ell(\alpha)$ and $N \geq \ell(\beta)$ (such an N clearly exists). Then, $\alpha = (\alpha_1, \alpha_2, ..., \alpha_N)$ and $\beta = (\beta_1, \beta_2, ..., \beta_N)$. Since $p = \sum_{(\lambda,\mu)\in\mathrm{Par}\times\mathrm{Par}} \rho_{\lambda,\mu} m_\lambda \otimes m_\mu$, we have

$$\mathcal{E}_N(p) = \sum_{(\lambda,\mu)\in\mathrm{Par}\times\mathrm{Par}} \rho_{\lambda,\mu} m_\lambda(x_1, x_2, ..., x_N) m_\mu(y_1, y_2, ..., y_N). \tag{13.83.8}$$

The only addend on the right hand side of this equality which has a nonzero coefficient before $x_1^{\alpha_1} x_2^{\alpha_2} ... x_N^{\alpha_N} y_1^{\beta_1} y_2^{\beta_2} ... y_N^{\beta_N}$ is the addend for $(\lambda, \mu) = (\alpha, \beta)$ (since α and β are partitions, so the only partition λ such that the monomial $x_1^{\alpha_1} x_2^{\alpha_2} ... x_N^{\alpha_N}$ appears in $m_\lambda(x_1, x_2, ..., x_N)$ is α, and the only partition μ such that the monomial $y_1^{\beta_1} y_2^{\beta_2} ... y_N^{\beta_N}$ appears in $m_\mu(y_1, y_2, ..., y_N)$ is β). This coefficient is $\rho_{\alpha,\beta}$. Hence, (13.83.8) shows that the coefficient before $x_1^{\alpha_1} x_2^{\alpha_2} ... x_N^{\alpha_N} y_1^{\beta_1} y_2^{\beta_2} ... y_N^{\beta_N}$ in the power series $\mathcal{E}_N(p)$ is $\rho_{\alpha,\beta}$. But this coefficient must be an integer (in fact, (13.83.7) shows that every coefficient of the power series $\mathcal{E}_N(p)$ is an integer). Thus, $\rho_{\alpha,\beta}$ is an integer.

So we have shown that $\rho_{\alpha,\beta}$ is an integer for every $(\alpha, \beta) \in \mathrm{Par} \times \mathrm{Par}$. In other words, $\rho_{\lambda,\mu}$ is an integer for every $(\lambda, \mu) \in \mathrm{Par} \times \mathrm{Par}$. Now, $p = \sum_{(\lambda,\mu)\in\mathrm{Par}\times\mathrm{Par}} \underbrace{\rho_{\lambda,\mu}}_{\text{an integer}} m_\lambda \otimes m_\mu \in \Lambda \otimes_{\mathbb{Z}} \Lambda$. This proves (13.83.6).

Now, we are almost done. Let $p \in \Delta_\times(\Lambda)$. We know that $\mathcal{E}_N(p) \in \mathbb{Z}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N]$ for every $N \in \mathbb{N}$ (according to (13.83.5)). Hence, (13.83.6) yields that $p \in \Lambda \otimes_{\mathbb{Z}} \Lambda$. Since we have proven this for every $p \in \Delta_\times(\Lambda)$, we thus obtain $\Delta_\times(\Lambda) \subset \Lambda \otimes_{\mathbb{Z}} \Lambda$. This solves Exercise 2.9.4(b).

Third solution of Exercise 2.9.4(b): Here is another solution of Exercise 2.9.4(b), which entirely gets by without using substitutions. We are going to prove that

$$\Delta_\times(h_n) = \sum_{\lambda\vdash n} s_\lambda \otimes s_\lambda \qquad \text{for every } n \in \mathbb{N}. \tag{13.83.9}$$

[657] Once this is proven, it will follow that $\Delta_\times(h_n) \in \Lambda \otimes_{\mathbb{Z}} \Lambda$ for every $n \in \mathbb{N}$, and therefore

$$\begin{aligned}\Delta_\times\left(\underbrace{h_\lambda}_{=h_{\lambda_1}h_{\lambda_2}h_{\lambda_3}...}\right) &= \Delta_\times(h_{\lambda_1}h_{\lambda_2}h_{\lambda_3}...) \\ &= \underbrace{\Delta_\times(h_{\lambda_1})}_{\in\Lambda\otimes_{\mathbb{Z}}\Lambda} \cdot \underbrace{\Delta_\times(h_{\lambda_2})}_{\in\Lambda\otimes_{\mathbb{Z}}\Lambda} \cdot \underbrace{\Delta_\times(h_{\lambda_3})}_{\in\Lambda\otimes_{\mathbb{Z}}\Lambda} \cdot ... \qquad (\text{since } \Delta_\times \text{ is a } \mathbb{Q}\text{-algebra homomorphism}) \\ &\in (\Lambda \otimes_{\mathbb{Z}} \Lambda) \cdot (\Lambda \otimes_{\mathbb{Z}} \Lambda) \cdot (\Lambda \otimes_{\mathbb{Z}} \Lambda) \cdot ... \\ &\subset \Lambda \otimes_{\mathbb{Z}} \Lambda\end{aligned}$$

for every partition λ; and this will immediately yield that $\Delta_\times(\Lambda) \subset \Lambda \otimes_{\mathbb{Z}} \Lambda$ (because $\Delta_\times$ is $\mathbb{Z}$-linear, and because $(h_\lambda)_{\lambda\in\mathrm{Par}}$ is a basis of the $\mathbb{Z}$-module Λ), which will solve Exercise 2.9.4(b). Hence, in order to solve Exercise 2.9.4(b), it is enough to prove (13.83.9).

[657] The notation "$\lambda \vdash n$" here is a synonym for "$\lambda \in \mathrm{Par}_n$".

We need to prove (13.83.9). In order to do so, it is clearly enough to show that

$$\sum_{n\geq 0} \Delta_\times (h_n) t^n = \sum_{n\geq 0} \left(\sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda \right) t^n \qquad \text{in } (\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}) [[t]] \tag{13.83.10}$$

(because comparing coefficients in (13.83.10) immediately yields (13.83.9)).

Recall that for any two $\mathbb{Q}$-algebras $\mathcal{A}$ and $\mathcal{B}$, every $\mathbb{Q}$-algebra homomorphism $\varphi : \mathcal{A} \to \mathcal{B}$ induces a continuous[658] $\mathbb{Q}[[t]]$-algebra homomorphism $\varphi[[t]] : \mathcal{A}[[t]] \to \mathcal{B}[[t]]$ which is given by

$$(\varphi[[t]]) \left(\sum_{k\geq 0} a_k t^k \right) = \sum_{k\geq 0} \varphi(a_k) t^k \qquad \text{for every } (a_k)_{k\geq 0} \in \mathcal{A}^{\mathbb{N}}.$$

In particular, the $\mathbb{Q}$-algebra homomorphism $\Delta_\times : \Lambda_{\mathbb{Q}} \to \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ induces a $\mathbb{Q}[[t]]$-algebra homomorphism $\Delta_\times[[t]] : \Lambda_{\mathbb{Q}}[[t]] \to (\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}})[[t]]$. Recall the power series $H(t) \in \Lambda[[t]]$ defined in (2.4.1); it satisfies $H(t) = \sum_{n\geq 0} h_n t^n$. Applying the map $\Delta_\times[[t]]$ to both sides of this equality, we obtain

$$(\Delta_\times[[t]])(H(t)) = (\Delta_\times[[t]]) \left(\sum_{n\geq 0} h_n t^n \right) = \sum_{n\geq 0} \Delta_\times (h_n) t^n \tag{13.83.11}$$

(by the definition of $\Delta_\times[[t]]$).

On the other hand, recall the $\mathbb{Q}$-algebra isomorphism $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to R_{\mathbb{Q}}(\mathbf{x},\mathbf{y})^{\mathfrak{S}_{(\infty)} \times \mathfrak{S}_{(\infty)}}$ constructed in (2.1.3) (applied to $\mathbf{k} = \mathbb{Q}$). This entails a $\mathbb{Q}$-algebra injection $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to \mathbb{Q}[[\mathbf{x},\mathbf{y}]]$ (since $R_{\mathbb{Q}}(\mathbf{x},\mathbf{y})^{\mathfrak{S}_{(\infty)} \times \mathfrak{S}_{(\infty)}} \subset R_{\mathbb{Q}}(\mathbf{x},\mathbf{y}) \subset \mathbb{Q}[[\mathbf{x},\mathbf{y}]]$). Denote this injection by ι. Then, the $\mathbb{Q}$-algebra homomorphism $\iota : \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to \mathbb{Q}[[\mathbf{x},\mathbf{y}]]$ induces a $\mathbb{Q}[[t]]$-algebra homomorphism $\iota[[t]] : (\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}})[[t]] \to \mathbb{Q}[[\mathbf{x},\mathbf{y}]][[t]]$. This homomorphism $\iota[[t]]$ is injective (since ι is injective).

We need to prove (13.83.10). For this, it is enough to prove

$$(\iota[[t]]) \left(\sum_{n\geq 0} \Delta_\times (h_n) t^n \right) = (\iota[[t]]) \left(\sum_{n\geq 0} \left(\sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda \right) t^n \right) \tag{13.83.12}$$

(because the injectivity of $\iota[[t]]$ ensures that (13.83.12) implies (13.83.10)).

In $\mathbb{Q}[[\mathbf{x},\mathbf{y}]][[t]]$, we have

$$\begin{aligned}
(\iota[[t]]) \left(\sum_{n\geq 0} \left(\sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda \right) t^n \right) &= \sum_{n\geq 0} \underbrace{\iota \left(\sum_{\lambda \vdash n} s_\lambda \otimes s_\lambda \right)}_{\substack{= \sum_{\lambda \vdash n} s_\lambda(\mathbf{x}) s_\lambda(\mathbf{y}) \\ \text{(by the definition of } \iota\text{)}}} t^n \\
&= \sum_{n\geq 0} \sum_{\lambda \vdash n} s_\lambda(\mathbf{x}) s_\lambda(\mathbf{y}) t^n = \sum_{\lambda \in \mathrm{Par}} s_\lambda(\mathbf{x}) \underbrace{s_\lambda(\mathbf{y}) t^{|\lambda|}}_{\substack{= s_\lambda(ty_1, ty_2, ty_3, \ldots) \\ \text{(since } s_\lambda \text{ is homogeneous of degree } |\lambda|\text{)}}} \\
&= \sum_{\lambda \in \mathrm{Par}} s_\lambda(\mathbf{x}) s_\lambda(ty_1, ty_2, ty_3, \ldots) = \prod_{i,j=1}^{\infty} (1 - x_i \cdot ty_j)^{-1} \qquad (13.83.13) \\
&\left(\begin{array}{c} \text{since (2.5.1) (applied to } (ty_1, ty_2, ty_3, \ldots) \text{ instead of } \mathbf{y}) \\ \text{yields } \prod_{i,j=1}^{\infty} (1 - x_i \cdot ty_j)^{-1} = \sum_{\lambda \in \mathrm{Par}} s_\lambda(\mathbf{x}) s_\lambda(ty_1, ty_2, ty_3, \ldots) \end{array} \right).
\end{aligned}$$

Meanwhile, exponentiating both sides of the equality (2.5.12) yields

$$H(t) = \exp \left(\sum_{m=1}^{\infty} \frac{1}{m} p_m(\mathbf{x}) t^m \right),$$

[658] The word "continuous" refers to the usual topologies on the power series rings $\mathcal{A}[[t]]$ and $\mathcal{B}[[t]]$.

so that

$$
\begin{aligned}
\left(\Delta_{\times}[[t]]\right)(H(t)) &= \left(\Delta_{\times}[[t]]\right)\left(\exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m(\mathbf{x})\,t^m\right)\right) = \exp\left(\underbrace{\left(\Delta_{\times}[[t]]\right)\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m(\mathbf{x})\,t^m\right)}_{=\sum_{m=1}^{\infty}\Delta_{\times}\left(\frac{1}{m}p_m(\mathbf{x})\right)t^m}\right)\\
&\qquad\left(\begin{array}{c}\text{since } \Delta_{\times}[[t]] \text{ is a continuous } \mathbb{Q}\text{-algebra homomorphism,}\\ \text{and thus commutes with } \exp\end{array}\right)\\
&= \exp\left(\sum_{m=1}^{\infty}\underbrace{\Delta_{\times}\left(\frac{1}{m}p_m(\mathbf{x})\right)}_{=\dfrac{1}{m}\Delta_{\times}(p_m(\mathbf{x}))}t^m\right) = \exp\left(\sum_{m=1}^{\infty}\frac{1}{m}\underbrace{\Delta_{\times}(p_m(\mathbf{x}))}_{\substack{=\Delta_{\times}(p_m)=p_m\otimes p_m\\ \text{(by the definition of }\Delta_{\times}\text{)}}}t^m\right)\\
&= \exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m\otimes p_m t^m\right).
\end{aligned}
$$

Compared with (13.83.11), this yields

$$
\sum_{n\geq 0}\Delta_{\times}(h_n)\,t^n = \exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m\otimes p_m t^m\right).
$$

Applying the map $\iota[[t]]$ to both sides of this equality, we obtain

$$
\begin{aligned}
\left(\iota[[t]]\right)\left(\sum_{n\geq 0}\Delta_{\times}(h_n)\,t^n\right) &= \left(\iota[[t]]\right)\left(\exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m\otimes p_m t^m\right)\right) = \exp\left(\underbrace{\left(\iota[[t]]\right)\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m\otimes p_m t^m\right)}_{=\sum_{m=1}^{\infty}\iota\left(\frac{1}{m}p_m\otimes p_m\right)t^m}\right)\\
&\qquad\left(\begin{array}{c}\text{since } \iota[[t]] \text{ is a continuous } \mathbb{Q}\text{-algebra homomorphism,}\\ \text{and thus commutes with } \exp\end{array}\right)\\
&= \exp\left(\sum_{m=1}^{\infty}\underbrace{\iota\left(\frac{1}{m}p_m\otimes p_m\right)}_{\substack{=\dfrac{1}{m}p_m(\mathbf{x})p_m(\mathbf{y})\\ \text{(by the definition of }\iota\text{)}}}t^m\right) = \exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m(\mathbf{x})\underbrace{p_m(\mathbf{y})\,t^m}_{\substack{=p_m(ty_1,ty_2,ty_3,\ldots)\\ \text{(since } p_m \text{ is homogeneous of}\\ \text{degree } m\text{)}}}\right)\\
&= \exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m(\mathbf{x})\,p_m(ty_1,ty_2,ty_3,\ldots)\right). \qquad (13.83.14)
\end{aligned}
$$

But exponentiating both sides of the equality (2.5.14) yields

$$
\prod_{i,j=1}^{\infty}\left(1-x_iy_j\right)^{-1} = \exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m(\mathbf{x})\,p_m(\mathbf{y})\right).
$$

Substituting $(ty_1,ty_2,ty_3,\ldots)$ for $\mathbf{y}$ in this equality, we obtain

$$
\prod_{i,j=1}^{\infty}\left(1-x_i\cdot ty_j\right)^{-1} = \exp\left(\sum_{m=1}^{\infty}\frac{1}{m}p_m(\mathbf{x})\,p_m(ty_1,ty_2,ty_3,\ldots)\right).
$$

Compared with (13.83.14), this yields

$$(\iota\left[\left[t\right]\right])\left(\sum_{n\geq 0}\Delta_{\times}\left(h_n\right)t^n\right)=\prod_{i,j=1}^{\infty}\left(1-x_i\cdot ty_j\right)^{-1}.$$

Compared with (13.83.13), this yields

$$(\iota\left[\left[t\right]\right])\left(\sum_{n\geq 0}\Delta_{\times}\left(h_n\right)t^n\right)=(\iota\left[\left[t\right]\right])\left(\sum_{n\geq 0}\left(\sum_{\lambda\vdash n}s_\lambda\otimes s_\lambda\right)t^n\right).$$

This proves (13.83.12). Thus, Exercise 2.9.4(b) is solved.

Remark: The three solutions we gave for Exercise 2.9.4(b) are not that different. The Second solution is a variation on the First solution which trades the use of a substitution of infinitely many variables (with the technical troubles that come along with it) for the inconvenience of having to consider a "sufficiently high $N\in\mathbb{N}$". The Third solution looks like a different beast, but its main idea – the equality (13.83.9) – is really just an afterthought of the First solution. Indeed, knowing the equality (13.83.3) in the First solution, we can easily prove (13.83.9) as follows: Using the notations of the First solution, we have

$$\begin{aligned}\sum_{n\geq 0}h_n\left(\left(x_iy_j\right)_{(i,j)\in\{1,2,3,\ldots\}^2}\right)t^n&=\prod_{i,j=1}^{\infty}\left(1-tx_iy_j\right)^{-1}&&\text{(by (2.2.18), evaluated on the variable set }\mathbf{xy}\text{)}\\&=\sum_{\lambda\in\operatorname{Par}}t^{|\lambda|}s_\lambda\left(\mathbf{x}\right)s_\lambda\left(\mathbf{y}\right)&&\text{(by (2.5.2))}\\&=\sum_{n\in\mathbb{N}}\left(\sum_{\lambda\vdash n}s_\lambda\left(\mathbf{x}\right)s_\lambda\left(\mathbf{y}\right)\right)t^n\end{aligned}$$

in $\mathbb{Q}\left[\left[\mathbf{x},\mathbf{y}\right]\right]\left[\left[t\right]\right]$. Comparing coefficients before t^n in this equality, we obtain

$$h_n\left(\left(x_iy_j\right)_{(i,j)\in\{1,2,3,\ldots\}^2}\right)=\sum_{\lambda\vdash n}s_\lambda\left(\mathbf{x}\right)s_\lambda\left(\mathbf{y}\right)\qquad\text{for every }n\in\mathbb{N}.$$

Thus, for every $n\in\mathbb{N}$, we have

$$\begin{aligned}\iota\left(\Delta_{\times}\left(h_n\right)\right)&=\underbrace{\left(\iota\circ\Delta_{\times}\right)}_{\substack{=\widetilde{\Delta}_{\times}\\\text{(by (13.83.3))}}}\left(h_n\right)=\widetilde{\Delta}_{\times}\left(h_n\right)=h_n\left(\left(x_iy_j\right)_{(i,j)\in\{1,2,3,\ldots\}^2}\right)=\sum_{\lambda\vdash n}s_\lambda\left(\mathbf{x}\right)s_\lambda\left(\mathbf{y}\right)\\&=\iota\left(\sum_{\lambda\vdash n}s_\lambda\otimes s_\lambda\right),\end{aligned}$$

which (by the injectivity of ι) yields $\Delta_{\times}\left(h_n\right)=\sum_{\lambda\vdash n}s_\lambda\otimes s_\lambda$. Thus, (13.83.9) is proven again.

In a similar vein, one can show that

$$\Delta_{\times}\left(e_n\right)=\sum_{\lambda\vdash n}s_\lambda\otimes s_{\lambda^t}\qquad\text{for every }n\in\mathbb{N}.$$

(One would need to use the dual Cauchy identity, i.e., Exercise 2.7.12(a), instead of (2.5.2) this time.)

(c) We are going to show that

$$\epsilon_r\left(h_n\right)=\left(-1\right)^n\binom{-r}{n}\qquad\text{for every }n\in\mathbb{N}.\tag{13.83.15}$$

This will yield the statement of Exercise 2.9.4(c) in the same way as (13.83.9) yielded the statement of Exercise 2.9.4(b) in the Third solution of Exercise 2.9.4(b) above. Hence, we only need to prove (13.83.15) in order to be done with Exercise 2.9.4(c).

Recall that for any two $\mathbb{Q}$-algebras $\mathcal{A}$ and $\mathcal{B}$, every $\mathbb{Q}$-algebra homomorphism $\varphi : \mathcal{A} \to \mathcal{B}$ induces a continuous[659] $\mathbb{Q}[[t]]$-algebra homomorphism $\varphi[[t]] : \mathcal{A}[[t]] \to \mathcal{B}[[t]]$ which is given by

$$(\varphi[[t]])\left(\sum_{k\geq 0} a_k t^k\right) = \sum_{k\geq 0} \varphi(a_k) t^k \qquad \text{for every } (a_k)_{k\geq 0} \in \mathcal{A}^{\mathbb{N}}.$$

Hence, the $\mathbb{Q}$-algebra homomorphism $\epsilon_r : \Lambda_{\mathbb{Q}} \to \mathbb{Q}$ induces a continuous $\mathbb{Q}[[t]]$-algebra homomorphism $\epsilon_r[[t]] : \Lambda_{\mathbb{Q}}[[t]] \to \mathbb{Q}[[t]]$.

Recall the power series $H(t) \in \Lambda[[t]]$ defined in (2.4.1); it satisfies $H(t) = \sum_{n\geq 0} h_n t^n$. Applying the homomorphism $\epsilon_r[[t]]$ to both sides of this equality, we obtain

$$(\epsilon_r[[t]])(H(t)) = (\epsilon_r[[t]])\left(\sum_{n\geq 0} h_n t^n\right) = \sum_{n\geq 0} \epsilon_r(h_n) t^n. \tag{13.83.16}$$

On the other hand, exponentiating both sides of the equality (2.5.12) yields

$$H(t) = \exp\left(\sum_{m=1}^{\infty} \frac{1}{m} p_m(\mathbf{x}) t^m\right).$$

Applying the map $\epsilon_r[[t]]$ to both sides of this equality, we obtain

$$\begin{aligned}
(\epsilon_r[[t]])(H(t)) &= (\epsilon_r[[t]])\left(\exp\left(\sum_{m=1}^{\infty} \frac{1}{m} p_m(\mathbf{x}) t^m\right)\right) = \exp\left(\underbrace{(\epsilon_r[[t]])\left(\sum_{m=1}^{\infty} \frac{1}{m} p_m(\mathbf{x}) t^m\right)}_{=\sum_{m=1}^{\infty} \epsilon_r\left(\frac{1}{m} p_m(\mathbf{x})\right) t^m}\right) \\
&\qquad \left(\begin{array}{c}\text{since } \epsilon_r[[t]] \text{ is a continuous } \mathbb{Q}\text{-algebra homomorphism,} \\ \text{and thus commutes with } \exp\end{array}\right) \\
&= \exp\left(\sum_{m=1}^{\infty} \underbrace{\epsilon_r\left(\frac{1}{m} p_m(\mathbf{x})\right)}_{=\epsilon_r\left(\frac{1}{m} p_m\right) = \frac{1}{m}\epsilon_r(p_m)} t^m\right) = \exp\left(\sum_{m=1}^{\infty} \frac{1}{m} \underbrace{\epsilon_r(p_m)}_{\substack{=r \\ \text{(by the definition of } \epsilon_r)}} t^m\right) \\
&= \exp\left(\sum_{m=1}^{\infty} \frac{1}{m} r t^m\right) = \exp\left(r \cdot \underbrace{\sum_{m=1}^{\infty} \frac{1}{m} t^m}_{=-\log(1-t)}\right) = \exp(r \cdot (-\log(1-t))) \\
&= \left(\underbrace{\exp(-\log(1-t))}_{=(1-t)^{-1}}\right)^r = \left((1-t)^{-1}\right)^r = (1-t)^{-r} = \sum_{n\geq 0} (-1)^n \binom{-r}{n} t^n
\end{aligned}$$

(by Newton's binomial formula). Comparing this with (13.83.16), we obtain

$$\sum_{n\geq 0} \epsilon_r(h_n) t^n = \sum_{n\geq 0} (-1)^n \binom{-r}{n} t^n.$$

Comparing coefficients in this equality of power series, we see that $\epsilon_r(h_n) = (-1)^n \binom{-r}{n}$ for every $n \in \mathbb{N}$. Thus, (13.83.15) is proven, and so Exercise 2.9.4(c) is solved.

[659] The word "continuous" refers to the usual topologies on the power series rings $\mathcal{A}[[t]]$ and $\mathcal{B}[[t]]$.

(d) Consider the $\mathbb{Q}$-algebra homomorphism ϵ_r defined in Exercise 2.9.4(c), and the $\mathbb{Q}$-algebra homomorphism $\Delta_\times$ defined in Exercise 2.9.4(b). We know that both of these maps ϵ_r and $\Delta_\times$ are $\mathbb{Q}$-algebra homomorphisms. In particular, $\operatorname{id} : \Lambda_{\mathbb{Q}} \to \Lambda_{\mathbb{Q}}$ and $\epsilon_r : \Lambda_{\mathbb{Q}} \to \mathbb{Q}$ are $\mathbb{Q}$-algebra homomorphisms. Thus, $\operatorname{id} \otimes \epsilon_r : \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \mathbb{Q}$ is a $\mathbb{Q}$-algebra homomorphism (by Exercise 1.3.6(a)). Also, let $\operatorname{can} : \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \mathbb{Q} \to \Lambda_{\mathbb{Q}}$ be the canonical $\mathbb{Q}$-vector space isomorphism sending every $f \otimes \alpha \in \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \mathbb{Q}$ to $\alpha f \in \Lambda_{\mathbb{Q}}$.

Now, we claim that

$$\operatorname{can} \circ (\operatorname{id} \otimes \epsilon_r) \circ \Delta_\times = \mathbf{i}_r. \tag{13.83.17}$$

Proof of (13.83.17): The equality (13.83.17) is an equality between $\mathbb{Q}$-algebra homomorphisms (since can, $\operatorname{id} \otimes \epsilon_r$, $\Delta_\times$ and $\mathbf{i}_r$ are $\mathbb{Q}$-algebra homomorphisms). Consequently, in order to prove it, we only need to check that it holds on a generating set of the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$. We do this on the generating set $(p_n)_{n \geq 1}$, by noticing that every $n \geq 1$ satisfies

$$\begin{aligned}\left(\operatorname{can} \circ (\operatorname{id} \otimes \epsilon_r) \circ \Delta_\times\right)(p_n) &= \operatorname{can}\left((\operatorname{id} \otimes \epsilon_r)\left(\underbrace{\Delta_\times(p_n)}_{= p_n \otimes p_n}\right)\right) = \operatorname{can}\left(\underbrace{(\operatorname{id} \otimes \epsilon_r)(p_n \otimes p_n)}_{= p_n \otimes \epsilon_r(p_n)}\right) \\ &= \operatorname{can}(p_n \otimes \epsilon_r(p_n)) = \underbrace{\epsilon_r(p_n)}_{= r} p_n = r p_n = \mathbf{i}_r(p_n).\end{aligned}$$

This proves (13.83.17).

Now, $\underbrace{\left(\operatorname{can} \circ (\operatorname{id} \otimes \epsilon_r) \circ \Delta_\times\right)}_{= \mathbf{i}_r}(\Lambda) = \mathbf{i}_r(\Lambda)$, so that

$$\begin{aligned}\mathbf{i}_r(\Lambda) &= \left(\operatorname{can} \circ (\operatorname{id} \otimes \epsilon_r) \circ \Delta_\times\right)(\Lambda) = \operatorname{can}\left((\operatorname{id} \otimes \epsilon_r) \quad \underbrace{(\Delta_\times(\Lambda))}_{\substack{\subset \Lambda \otimes_{\mathbb{Z}} \Lambda \\ \text{(by Exercise 2.9.4(b))}}}\right) \subset \operatorname{can}\left(\underbrace{(\operatorname{id} \otimes \epsilon_r)(\Lambda \otimes_{\mathbb{Z}} \Lambda)}_{= \Lambda \otimes_{\mathbb{Z}} \epsilon_r(\Lambda)}\right) \\ &= \operatorname{can}\left(\Lambda \otimes_{\mathbb{Z}} \quad \underbrace{\epsilon_r(\Lambda)}_{\substack{\subset \mathbb{Z} \\ \text{(by Exercise 2.9.4(c))}}}\right) \subset \operatorname{can}(\Lambda \otimes \mathbb{Z}) = \mathbb{Z} \cdot \Lambda \qquad \text{(by the definition of can)} \\ &= \Lambda.\end{aligned}$$

This solves Exercise 2.9.4(d).

(e) Consider the $\mathbb{Q}$-algebra homomorphism $\Delta_\times$ defined in Exercise 2.9.4(b). We have $\Delta_\times(p_n) = p_n \otimes p_n$ for every positive integer n. Now, it is easy to see that

$$\Delta_\times(p_\lambda) = p_\lambda \otimes p_\lambda \qquad \text{for every partition } \lambda. \tag{13.83.18}$$

[660]

Now, consider the multiplication map $m_{\Lambda_{\mathbb{Q}}} : \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to \Lambda_{\mathbb{Q}}$ of the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$. We claim that

$$\operatorname{Sq} = m_{\Lambda_{\mathbb{Q}}} \circ \Delta_\times.$$

[660] *Proof of (13.83.18):* Let λ be a partition. Write λ in the form $\lambda = (\lambda_1, \lambda_2, ..., \lambda_\ell)$ with $\ell = \ell(\lambda)$. Then, the definition of p_λ yields $p_\lambda = p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell}$. Applying the map $\Delta_\times$ to both sides of this equality, we obtain

$$\begin{aligned}\Delta_\times(p_\lambda) &= \Delta_\times(p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell}) = \Delta_\times(p_{\lambda_1}) \cdot \Delta_\times(p_{\lambda_2}) \cdot ... \cdot \Delta_\times(p_{\lambda_\ell}) && \text{(since } \Delta_\times \text{ is a } \mathbb{Q}\text{-algebra homomorphism)} \\ &= (p_{\lambda_1} \otimes p_{\lambda_1}) \cdot (p_{\lambda_2} \otimes p_{\lambda_2}) \cdot ... \cdot (p_{\lambda_\ell} \otimes p_{\lambda_\ell}) && \text{(since } \Delta_\times(p_n) = p_n \otimes p_n \text{ for every positive integer } n\text{)} \\ &= \underbrace{(p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell})}_{= p_\lambda} \otimes \underbrace{(p_{\lambda_1} p_{\lambda_2} ... p_{\lambda_\ell})}_{= p_\lambda} = p_\lambda \otimes p_\lambda,\end{aligned}$$

which proves (13.83.18).

Indeed, every partition λ satisfies

$$\operatorname{Sq}(p_\lambda) = p_\lambda^2 = p_\lambda p_\lambda = m_{\Lambda_{\mathbb{Q}}}\left(\underbrace{p_\lambda \otimes p_\lambda}_{\substack{=\Delta_\times(p_\lambda) \\ (\text{by } (13.83.18))}}\right) = m_{\Lambda_{\mathbb{Q}}}\left(\Delta_\times(p_\lambda)\right) = \left(m_{\Lambda_{\mathbb{Q}}} \circ \Delta_\times\right)(p_\lambda).$$

Since $(p_\lambda)_{\lambda\in\operatorname{Par}}$ is a $\mathbb{Q}$-basis of $\Lambda_{\mathbb{Q}}$ (and since Sq and $m_{\Lambda_{\mathbb{Q}}} \circ \Delta_\times$ are $\mathbb{Q}$-linear maps), this shows that $\operatorname{Sq} = m_{\Lambda_{\mathbb{Q}}} \circ \Delta_\times$. Hence,

$$\begin{aligned}\operatorname{Sq}(\Lambda) = \left(m_{\Lambda_{\mathbb{Q}}} \circ \Delta_\times\right)(\Lambda) = m_{\Lambda_{\mathbb{Q}}} &\underbrace{\left(\Delta_\times(\Lambda)\right)}_{\substack{\subset \Lambda\otimes_{\mathbb{Z}}\Lambda \\ (\text{by Exercise 2.9.4(b)})}} \subset m_{\Lambda_{\mathbb{Q}}}\left(\Lambda \otimes_{\mathbb{Z}} \Lambda\right) \\ &= \Lambda \cdot \Lambda \qquad \left(\text{by the definition of } m_{\Lambda_{\mathbb{Q}}}\right) \\ &= \Lambda.\end{aligned}$$

This solves Exercise 2.9.4(e).

(f) For every $N \in \mathbb{N}$, we define a $\mathbb{Q}$-algebra homomorphism $\mathcal{E}_N : \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}} \to \mathbb{Q}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N]$ as it was done in our Second solution of Exercise 2.9.4(b).

Recall the definition of the maps $\mathbf{i}_r$ in Exercise 2.9.4(d). We are first going to show that every $a \in \mathbb{Z}$ and $b \in \mathbb{Z}$ satisfy

$$\Delta_a = \Delta_b \star \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right) \qquad \text{in } \operatorname{Hom}\left(\Lambda_{\mathbb{Q}}, \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}\right) \tag{13.83.19}$$

(where $\Delta_{\Lambda_{\mathbb{Q}}} : \Lambda_{\mathbb{Q}} \to \Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ is the usual comultiplication of $\Lambda_{\mathbb{Q}}$).

Proof of (13.83.19): Let $a \in \mathbb{Z}$ and $b \in \mathbb{Z}$. We know that Δ_a and Δ_b are $\mathbb{Q}$-algebra homomorphisms. Also, $\Delta_{\Lambda_{\mathbb{Q}}}$ is a $\mathbb{Q}$-algebra homomorphism (by the axioms of a bialgebra, which we know are satisfied for $\Lambda_{\mathbb{Q}}$), and $\mathbf{i}_{a-b}$ is a $\mathbb{Q}$-algebra homomorphism. Hence, the composition $\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}$ is a $\mathbb{Q}$-algebra homomorphism. Thus, the convolution $\Delta_b \star \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)$ is a $\mathbb{Q}$-algebra homomorphism (by Exercise 1.5.11(a), applied to $\mathbb{Q}$, $\Lambda_{\mathbb{Q}}$, $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$, Δ_b and $\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}$ instead of $\mathbf{k}$, H, A, f and g). Hence, (13.83.19) is an equality between $\mathbb{Q}$-algebra homomorphisms. Therefore, in order to prove it, we only need to check that it holds on a generating set of the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$. We do this on the generating set $(p_n)_{n\geq 1}$, by noticing that every $n \geq 1$ satisfies

$$\begin{aligned}
&\underbrace{\left(\Delta_b \star \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)\right)}_{\substack{= m_{\Lambda_{\mathbb{Q}}} \circ \left(\Delta_b \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)\right) \circ \Delta_{\Lambda_{\mathbb{Q}}} \\ \text{(by the definition of convolution)}}} (p_n) \\
&= \left(m_{\Lambda_{\mathbb{Q}}} \circ \left(\Delta_b \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)\right) \circ \Delta_{\Lambda_{\mathbb{Q}}}\right) (p_n) \\
&= m_{\Lambda_{\mathbb{Q}}} \left(\left(\Delta_b \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)\right) \left(\underbrace{\Delta_{\Lambda_{\mathbb{Q}}} (p_n)}_{\substack{= 1 \otimes p_n + p_n \otimes 1 \\ \text{(since } p_n \text{ is primitive)}}} \right) \right) \\
&= m_{\Lambda_{\mathbb{Q}}} \left(\underbrace{\left(\Delta_b \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)\right) (1 \otimes p_n + p_n \otimes 1)}_{= \Delta_b(1) \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)(p_n) + \Delta_b(p_n) \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right)(1)} \right) \\
&= m_{\Lambda_{\mathbb{Q}}} \left(\Delta_b (1) \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right) (p_n) + \Delta_b (p_n) \otimes \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right) (1) \right) \\
&= \underbrace{\Delta_b (1)}_{= 1 \otimes 1} \cdot \underbrace{\left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right) (p_n)}_{= \Delta_{\Lambda_{\mathbb{Q}}} (\mathbf{i}_{a-b}(p_n))} + \Delta_b (p_n) \cdot \underbrace{\left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b}\right) (1)}_{\substack{= 1 \otimes 1 \\ \text{(since } \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{a-b} \text{ is a } \mathbb{Q}\text{-algebra} \\ \text{homomorphism)}}} \\
&= (1 \otimes 1) \cdot \left(\Delta_{\Lambda_{\mathbb{Q}}} \left(\mathbf{i}_{a-b} (p_n)\right)\right) + \Delta_b (p_n) \cdot (1 \otimes 1) = \Delta_{\Lambda_{\mathbb{Q}}} \left(\underbrace{\mathbf{i}_{a-b} (p_n)}_{\substack{= (a-b) p_n \\ \text{(by the definition of } \mathbf{i}_{a-b})}} \right) + \underbrace{\Delta_b (p_n)}_{\substack{= \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + b \otimes p_n + p_n \otimes b \\ \text{(by the definition of } \Delta_b)}} \\
&= \Delta_{\Lambda_{\mathbb{Q}}} \left((a-b) p_n\right) + \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + b \otimes p_n + p_n \otimes b \\
&= (a-b) \underbrace{\Delta_{\Lambda_{\mathbb{Q}}} (p_n)}_{\substack{= 1 \otimes p_n + p_n \otimes 1 \\ \text{(since } p_n \text{ is primitive)}}} + \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + b \otimes p_n + p_n \otimes b \\
&= (a-b) (1 \otimes p_n + p_n \otimes 1) + \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + b \otimes p_n + p_n \otimes b \\
&= \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + \underbrace{b \otimes p_n + p_n \otimes b + (a-b) (1 \otimes p_n + p_n \otimes 1)}_{= a \otimes p_n + p_n \otimes a} \\
&= \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + a \otimes p_n + p_n \otimes a = \Delta_a (p_n) \\
&\qquad \left(\text{since the definition of } \Delta_a \text{ yields } \Delta_a (p_n) = \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + a \otimes p_n + p_n \otimes a \right).
\end{aligned}$$

This proves (13.83.19).

Before we move on, let us record a simple fact about convolution of maps. Namely, if $\mathbf{k}$ is a commutative ring, and C is a $\mathbf{k}$-coalgebra, and A and A' are two $\mathbf{k}$-algebras, and f and g are two $\mathbf{k}$-linear maps $C \to A$, and $\alpha : A \to A'$ is a $\mathbf{k}$-algebra homomorphism, then

$$\alpha \circ (f \star g) = (\alpha \circ f) \star (\alpha \circ g) . \tag{13.83.20}$$

This is merely the particular case of (1.4.2) when $C' = C$ and $\gamma = \operatorname{id}$, and so requires no proof anymore.

Now, let $N \in \mathbb{N}$. Our next goal is to show that

$$(\mathcal{E}_N \circ \Delta_N)(\Lambda) \subset \mathbb{Z}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N]. \tag{13.83.21}$$

Proof of (13.83.21): Let us define a map

$$\begin{aligned}\mathcal{L}_N : \Lambda_{\mathbb{Q}} &\to \mathbb{Q}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N], \\ f &\mapsto f\left((x_i + y_j)_{(i,j)\in\{1,2,...,N\}^2}\right).\end{aligned}$$

Here, $f\left((x_i + y_j)_{(i,j)\in\{1,2,...,N\}^2}\right)$ is defined as follows: Let $(u_1, u_2, ..., u_{N^2})$ be a list of all N^2 elements of the family $(x_i + y_j)_{(i,j)\in\{1,2,...,N\}^2}$ in any arbitrary order, and set $f\left((x_i + y_j)_{(i,j)\in\{1,2,...,N\}^2}\right) = f(u_1, u_2, ..., u_{N^2})$. (The result does not depend on the order chosen, because f is symmetric.)

The map $\mathcal{L}_N$ is a $\mathbb{Q}$-algebra homomorphism (since $\mathcal{L}_N$ is an evaluation map in an appropriate sense).

For every positive integer n, we have

$$\begin{aligned}\Delta_N(p_n) &= \sum_{i=1}^{n-1} \binom{n}{i} p_i \otimes p_{n-i} + N \otimes p_n + p_n \otimes N \qquad \text{(by the definition of } \Delta_N(p_n)\text{)} \\ &= \sum_{k=1}^{n-1} \binom{n}{k} p_k \otimes p_{n-k} + N \otimes p_n + p_n \otimes N\end{aligned}$$

and thus

$$\begin{aligned}&(\mathcal{E}_N \circ \Delta_N)(p_n) \\ &= \mathcal{E}_N\left(\underbrace{\Delta_N(p_n)}_{=\sum_{k=1}^{n-1}\binom{n}{k} p_k \otimes p_{n-k} + N \otimes p_n + p_n \otimes N}\right) = \mathcal{E}_N\left(\sum_{k=1}^{n-1} \binom{n}{k} p_k \otimes p_{n-k} + N \otimes p_n + p_n \otimes N\right) \\ &= \sum_{k=1}^{n-1} \binom{n}{k} \underbrace{p_k(x_1, x_2, ..., x_N)}_{=\sum_{i=1}^N x_i^k} \underbrace{p_{n-k}(y_1, y_2, ..., y_N)}_{=\sum_{j=1}^N y_j^{n-k}} + N \underbrace{p_n(y_1, y_2, ..., y_N)}_{=\sum_{j=1}^N y_j^n} + \underbrace{p_n(x_1, x_2, ..., x_N)}_{=\sum_{i=1}^N x_i^n} N \\ &\qquad \text{(by the definition of } \mathcal{E}_N\text{)} \\ &= \sum_{k=1}^{n-1} \binom{n}{k} \left(\sum_{i=1}^N x_i^k\right)\left(\sum_{j=1}^N y_j^{n-k}\right) + N\left(\sum_{j=1}^N y_j^n\right) + \left(\sum_{i=1}^N x_i^n\right) N, \qquad (13.83.22)\end{aligned}$$

while at the same time

$$\begin{aligned}
\mathcal{L}_N(p_n) &= p_n\left((x_i+y_j)_{(i,j)\in\{1,2,\ldots,N\}^2}\right) \qquad \text{(by the definition of } \mathcal{L}_N(p_n)\text{)} \\
&= \sum_{(i,j)\in\{1,2,\ldots,N\}^2} \underbrace{(x_i+y_j)^n}_{=\sum_{k=0}^n \binom{n}{k} x_i^k y_j^{n-k}} = \sum_{(i,j)\in\{1,2,\ldots,N\}^2} \sum_{k=0}^n \binom{n}{k} x_i^k y_j^{n-k} \\
&= \sum_{k=0}^n \binom{n}{k} \underbrace{\sum_{(i,j)\in\{1,2,\ldots,N\}^2} x_i^k y_j^{n-k}}_{=\left(\sum_{i=1}^N x_i^k\right)\left(\sum_{j=1}^N y_j^{n-k}\right)} = \sum_{k=0}^n \binom{n}{k} \left(\sum_{i=1}^N x_i^k\right)\left(\sum_{j=1}^N y_j^{n-k}\right) \\
&= \sum_{k=1}^{n-1} \binom{n}{k} \left(\sum_{i=1}^N x_i^k\right)\left(\sum_{j=1}^N y_j^{n-k}\right) + \underbrace{\binom{n}{0}}_{=1} \underbrace{\left(\sum_{i=1}^N x_i^0\right)}_{=N} \left(\sum_{j=1}^N y_j^n\right) + \underbrace{\binom{n}{n}}_{=1} \left(\sum_{i=1}^N x_i^n\right) \underbrace{\left(\sum_{j=1}^N y_j^0\right)}_{=N} \\
&= \sum_{k=1}^{n-1} \binom{n}{k} \left(\sum_{i=1}^N x_i^k\right)\left(\sum_{j=1}^N y_j^{n-k}\right) + N\left(\sum_{j=1}^N y_j^n\right) + \left(\sum_{i=1}^N x_i^n\right) N. \qquad (13.83.23)
\end{aligned}$$

Comparing (13.83.22) with (13.83.23) reveals that $(\mathcal{E}_N \circ \Delta_N)(p_n) = \mathcal{L}_N(p_n)$ for every positive integer n. In other words, the two maps $\mathcal{E}_N \circ \Delta_N$ and $\mathcal{L}_N$ are equal to each other on the generating set $(p_n)_{n\geq 1}$ of the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$. Since these two maps $\mathcal{E}_N \circ \Delta_N$ and $\mathcal{L}_N$ are $\mathbb{Q}$-algebra homomorphisms (since $\mathcal{E}_N$, Δ_N and $\mathcal{L}_N$ are $\mathbb{Q}$-algebra homomorphisms), this yields that these two maps must be identical, i.e., we have $\mathcal{E}_N \circ \Delta_N = \mathcal{L}_N$. Hence,

$$\underbrace{(\mathcal{E}_N \circ \Delta_N)}_{=\mathcal{L}_N}(\Lambda) = \mathcal{L}_N(\Lambda) \subset \mathbb{Z}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]$$

(because the definition of $\mathcal{L}_N$ immediately shows that $\mathcal{L}_N(f) \in \mathbb{Z}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]$ for every $f \in \Lambda$). This proves (13.83.21).

Next, we are going to show that

$$(\mathcal{E}_N \circ \Delta_r)(\Lambda) \subset \mathbb{Z}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]. \qquad (13.83.24)$$

Proof of (13.83.24): Applying (13.83.19) to $a = r$ and $b = N$, we obtain

$$\Delta_r = \Delta_N \star \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right).$$

Thus,

$$\mathcal{E}_N \circ \underbrace{\Delta_r}_{=\Delta_N \star \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)} = \mathcal{E}_N \circ \left(\Delta_N \star \left(\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)\right) = (\mathcal{E}_N \circ \Delta_N) \star \left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)$$

(by (13.83.20), applied to $\mathbb{Q}$, $\Lambda_{\mathbb{Q}}$, $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$, $\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]$, Δ_N, $\Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}$ and $\mathcal{E}_N$ instead of $\mathbf{k}$, C, A, A', f, g and α). Thus,

$$\mathcal{E}_N \circ \Delta_r = (\mathcal{E}_N \circ \Delta_N) \star \left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right) = m_{\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]} \circ \left((\mathcal{E}_N \circ \Delta_N) \otimes \left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)\right) \circ \Delta_{\Lambda_{\mathbb{Q}}}$$

(by the definition of convolution), so that

$$\begin{aligned}
&\underbrace{\left(\mathcal{E}_N \circ \Delta_r\right)}_{=m_{\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]}\circ\left(\left(\mathcal{E}_N\circ\Delta_N\right)\otimes\left(\mathcal{E}_N\circ\Delta_{\Lambda_{\mathbb{Q}}}\circ\mathbf{i}_{r-N}\right)\right)\circ\Delta_{\Lambda_{\mathbb{Q}}}} (\Lambda) \\
&= \left(m_{\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]} \circ \left(\left(\mathcal{E}_N \circ \Delta_N\right) \otimes \left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)\right) \circ \Delta_{\Lambda_{\mathbb{Q}}}\right)(\Lambda) \\
&= m_{\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]}\left(\left(\left(\mathcal{E}_N \circ \Delta_N\right) \otimes \left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)\right) \underbrace{\left(\Delta_{\Lambda_{\mathbb{Q}}}(\Lambda)\right)}_{=\Delta_\Lambda(\Lambda)\subset\Lambda\otimes_{\mathbb{Z}}\Lambda}\right) \\
&\subset m_{\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]}\left(\underbrace{\left(\left(\mathcal{E}_N \circ \Delta_N\right) \otimes \left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)\right)\left(\Lambda\otimes_{\mathbb{Z}}\Lambda\right)}_{=\left(\mathcal{E}_N\circ\Delta_N\right)(\Lambda)\otimes_{\mathbb{Z}}\left(\mathcal{E}_N\circ\Delta_{\Lambda_{\mathbb{Q}}}\circ\mathbf{i}_{r-N}\right)(\Lambda)}\right) \\
&= m_{\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]}\left(\left(\mathcal{E}_N \circ \Delta_N\right)(\Lambda) \otimes_{\mathbb{Z}} \left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)(\Lambda)\right) \\
&= \left(\mathcal{E}_N \circ \Delta_N\right)(\Lambda) \cdot \underbrace{\left(\mathcal{E}_N \circ \Delta_{\Lambda_{\mathbb{Q}}} \circ \mathbf{i}_{r-N}\right)(\Lambda)}_{=\mathcal{E}_N\left(\Delta_{\Lambda_{\mathbb{Q}}}\left(\mathbf{i}_{r-N}(\Lambda)\right)\right)} \qquad \left(\text{since } m_{\mathbb{Q}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N]} \text{ is the multiplication map}\right) \\
&= \left(\mathcal{E}_N \circ \Delta_N\right)(\Lambda) \cdot \mathcal{E}_N\left(\Delta_{\Lambda_{\mathbb{Q}}}\left(\underbrace{\mathbf{i}_{r-N}(\Lambda)}_{\substack{\subset\Lambda \\ \text{(by Exercise 2.9.4(d),} \\ \text{applied to } r-N \text{ instead of } r)}}\right)\right) \\
&\subset \underbrace{\left(\mathcal{E}_N \circ \Delta_N\right)(\Lambda)}_{\substack{\subset\mathbb{Z}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N] \\ \text{(by (13.83.21))}}} \cdot \mathcal{E}_N \underbrace{\left(\Delta_{\Lambda_{\mathbb{Q}}}(\Lambda)\right)}_{=\Delta_\Lambda(\Lambda)\subset\Lambda\otimes_{\mathbb{Z}}\Lambda} \\
&\subset \mathbb{Z}\left[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N\right] \cdot \underbrace{\mathcal{E}_N\left(\Lambda\otimes_{\mathbb{Z}}\Lambda\right)}_{\substack{\subset\mathbb{Z}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N] \\ \text{(because the definition of } \mathcal{E}_N \text{ immediately yields} \\ \mathcal{E}_N(f\otimes g)\in\mathbb{Z}[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N] \text{ for any } f\in\Lambda \text{ and } g\in\Lambda)}} \\
&\subset \mathbb{Z}\left[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N\right] \cdot \mathbb{Z}\left[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N\right] = \mathbb{Z}\left[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N\right].
\end{aligned}$$

This proves (13.83.24).

Now, forget that we fixed N. We thus have proven (13.83.24) to hold for every $N \in \mathbb{N}$.

Now, let $p \in \Delta_r(\Lambda)$. Then,

$$\mathcal{E}_N\left(\underbrace{p}_{\in\Delta_r(\Lambda)}\right) \in \mathcal{E}_N\left(\Delta_r(\Lambda)\right) = \left(\mathcal{E}_N \circ \Delta_r\right)(\Lambda) \in \mathbb{Z}\left[x_1,x_2,\ldots,x_N,y_1,y_2,\ldots,y_N\right] \qquad \text{(by (13.83.24))}$$

for every $N \in \mathbb{N}$. Hence, (13.83.6) yields that $p \in \Lambda \otimes_{\mathbb{Z}} \Lambda$. Since we have shown this for every $p \in \Delta_r(\Lambda)$, we thus conclude that $\Delta_r(\Lambda) \subset \Lambda \otimes_{\mathbb{Z}} \Lambda$. This solves Exercise 2.9.4(f).

Remark. Here is a rough sketch of an alternative way to conclude this solution of Exercise 2.9.4(f) after proving (13.83.21). This is closer to Richard Stanley's suggested solution than the above.

The family $(m_\lambda \otimes m_\mu)_{(\lambda,\mu)\in\operatorname{Par}\times\operatorname{Par}}$ is a $\mathbb{Q}$-basis of $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ (since $(m_\lambda)_{\lambda\in\operatorname{Par}}$ is a $\mathbb{Q}$-basis of $\Lambda_{\mathbb{Q}}$). Let us refer to this basis as the *monomial basis* of $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$. Then, $\Lambda \otimes_{\mathbb{Z}} \Lambda$ is the subset of $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ consisting of all elements whose coordinates with respect to the monomial basis all are integers.

We want to prove that $\Delta_r(\Lambda) \subset \Lambda \otimes_{\mathbb{Z}} \Lambda$ for every $r \in \mathbb{Z}$. In other words, we want to prove that $\Delta_r(f) \in \Lambda \otimes_{\mathbb{Z}} \Lambda$ for every $r \in \mathbb{Z}$ and $f \in \Lambda$. Let us fix $f \in \Lambda$, but not fix r. We need to show that $\Delta_r(f) \in \Lambda \otimes_{\mathbb{Z}} \Lambda$ for every $r \in \mathbb{Z}$; in other words, we need to show that for every $(\alpha, \beta) \in \operatorname{Par}$, the $m_\alpha \otimes m_\beta$-coordinate of $\Delta_r(f)$ with respect to the monomial basis is an integer for every $r \in \mathbb{Z}$.

So let us fix $(\alpha, \beta) \in \operatorname{Par}$. It is not hard to see that the $m_\alpha \otimes m_\beta$-coordinate of $\Delta_r(f)$ with respect to the monomial basis is a polynomial in r with rational coefficients.[661] We want to prove that this polynomial is integer-valued (i.e., all its values at integer inputs are integers[662]). To do so, it suffices to show that its values are integers **at all sufficiently high** $r \in \mathbb{Z}$ (because for a polynomial with rational coefficients, the non-integer values appear periodically[663], and therefore if no non-integer values appear from a given integer onwards, then the polynomial is integer-valued). In other words, it suffices to show that the $m_\alpha \otimes m_\beta$-coordinate of $\Delta_r(f)$ with respect to the monomial basis is an integer for all **sufficiently high** $r \in \mathbb{Z}$.

Let us prove this now. Our interpretation of "sufficiently high" will be that $r \geq \ell(\alpha)$ and $r \geq \ell(\beta)$. So what we need to prove is that the $m_\alpha \otimes m_\beta$-coordinate of $\Delta_r(f)$ with respect to the monomial basis is an integer whenever r is an integer satisfying $r \geq \ell(\alpha)$ and $r \geq \ell(\beta)$.

Consider such an r. Set $N = r$ and $p = \Delta_r(f)$. Then, $N = r \geq \ell(\alpha)$ and $N = r \geq \ell(\beta)$ and $\Delta_N(f) = \Delta_r(f) = p$. Then,

$$\mathcal{E}_N\left(\underbrace{p}_{=\Delta_N(f)}\right) = \mathcal{E}_N(\Delta_N(f)) = (\mathcal{E}_N \circ \Delta_N)\left(\underbrace{f}_{\in\Lambda}\right) \in (\mathcal{E}_N \circ \Delta_N)(\Lambda) \subset \mathbb{Z}[x_1, x_2, ..., x_N, y_1, y_2, ..., y_N]$$

(by (13.83.21)). Therefore, arguing precisely as in the proof of (13.83.6) (but using our specific α and β rather than arbitrary α and β as in that proof), we can show that $\rho_{\alpha,\beta}$ is an integer, where p is written in the form $p = \sum_{(\lambda,\mu)\in \operatorname{Par}\times\operatorname{Par}} \rho_{\lambda,\mu} m_\lambda \otimes m_\mu$ with $\rho_{\lambda,\mu}$ being elements of $\mathbb{Q}$. But $\rho_{\alpha,\beta}$ is precisely the $m_\alpha \otimes m_\beta$-coordinate of $\Delta_r(f)$ with respect to the monomial basis. Thus, we have shown that the $m_\alpha \otimes m_\beta$-coordinate of $\Delta_r(f)$ with respect to the monomial basis is an integer (for $r \in \mathbb{Z}$ satisfying $r \geq \ell(\alpha)$ and $r \geq \ell(\beta)$). As we know, this completes our solution of Exercise 2.9.4(f) again.

(g) Let us first show that the $\mathbb{Q}$-module $\Lambda_\mathbb{Q}$, endowed with the comultiplication $\Delta_\times$ and the counit ϵ_1, becomes a $\mathbb{Q}$-coalgebra. In order to do so, we must verifying that the diagrams (1.2.1) and (1.2.2), with C, Δ and ϵ replaced by $\Lambda_\mathbb{Q}$, $\Delta_\times$ and ϵ_1, commute. We will only do this for the diagram (1.2.1), while leaving the diagram (1.2.2) to the reader.

So we must check that the diagram (1.2.1), with C, Δ and ϵ replaced by $\Lambda_\mathbb{Q}$, $\Delta_\times$ and ϵ_1, commutes. In other words, we must prove the identity

$$(\Delta_\times \otimes \operatorname{id}) \circ \Delta_\times = (\operatorname{id} \otimes \Delta_\times) \circ \Delta_\times . \tag{13.83.25}$$

Proof of (13.83.17): The equality (13.83.25) is an equality between $\mathbb{Q}$-algebra homomorphisms (since $\Delta_\times$, $\operatorname{id} \otimes \Delta_\times$ and $\Delta_\times \otimes \operatorname{id}$ are $\mathbb{Q}$-algebra homomorphisms[664]). Consequently, in order to prove it, we only need to check that it holds on a generating set of the $\mathbb{Q}$-algebra $\Lambda_\mathbb{Q}$. But every $n \geq 1$ satisfies

$$((\Delta_\times \otimes \operatorname{id}) \circ \Delta_\times)(p_n) = (\Delta_\times \otimes \operatorname{id})\left(\underbrace{\Delta_\times(p_n)}_{=p_n \otimes p_n}\right) = (\Delta_\times \otimes \operatorname{id})(p_n \otimes p_n) = \underbrace{\Delta_\times(p_n)}_{=p_n \otimes p_n} \otimes p_n = p_n \otimes p_n \otimes p_n$$

and similarly $((\operatorname{id} \otimes \Delta_\times) \circ \Delta_\times)(p_n) = p_n \otimes p_n \otimes p_n$. Hence, every $n \geq 1$ satisfies $((\Delta_\times \otimes \operatorname{id}) \circ \Delta_\times)(p_n) = p_n \otimes p_n \otimes p_n = ((\operatorname{id} \otimes \Delta_\times) \circ \Delta_\times)(p_n)$. Thus, we have checked that the equality (13.83.25) holds on a generating set of the $\mathbb{Q}$-algebra $\Lambda_\mathbb{Q}$ (namely, on the generating set $(p_n)_{n\geq 1}$). As a consequence, the proof of (13.83.25) is complete.

We have thus shown that the $\mathbb{Q}$-module $\Lambda_\mathbb{Q}$, endowed with the comultiplication $\Delta_\times$ and the counit ϵ_1, becomes a $\mathbb{Q}$-coalgebra. This $\mathbb{Q}$-coalgebra becomes a $\mathbb{Q}$-bialgebra when combined with the existing $\mathbb{Q}$-algebra structure on $\Lambda_\mathbb{Q}$ (this is because $\Delta_\times$ and ϵ_1 are $\mathbb{Q}$-algebra homomorphisms), and this $\mathbb{Q}$-bialgebra is cocommutative (this follows from the equality $T \circ \Delta_\times = \Delta_\times$, where $T : \Lambda_\mathbb{Q} \otimes_\mathbb{Q} \Lambda_\mathbb{Q} \to \Lambda_\mathbb{Q} \otimes_\mathbb{Q} \Lambda_\mathbb{Q}$ is the twist map; and this equality can be proven in the same way as we have showed (13.83.25)). This solves Exercise 2.9.4(g).

[661] This can be proven by noticing that it holds whenever $f = p_n$ for some $n \geq 1$ (by inspection of the definition of Δ_r), and if it holds for two given values of f then it holds for any of their $\mathbb{Q}$-linear combinations and also for their product.

[662] This is a weaker statement than saying that it has integer coefficients. (Actually, it does not in general have integer coefficients.)

[663] To see this, just work modulo the common denominator of the coefficients of the polynomial.

[664] Here, we are using Exercise 1.3.6(a) to see that $\operatorname{id} \otimes \Delta_\times$ and $\Delta_\times \otimes \operatorname{id}$ are $\mathbb{Q}$-algebra homomorphisms.

(h) Corollary 2.5.17(b) yields that $(p_\lambda)_{\lambda\in\operatorname{Par}}$ and $\left(z_\lambda^{-1}p_\lambda\right)_{\lambda\in\operatorname{Par}}$ are dual bases with respect to the Hall inner product on Λ. In other words,

$$\left(p_\lambda, z_\mu^{-1}p_\mu\right) = \delta_{\lambda,\mu} \qquad \text{for any partitions } \lambda \text{ and } \mu.$$

Hence,

$$\left(p_\lambda, \underbrace{p_\mu}_{=z_\mu z_\mu^{-1}p_\mu}\right) = \left(p_\lambda, z_\mu z_\mu^{-1}p_\mu\right) = z_\mu \underbrace{\left(p_\lambda, z_\mu^{-1}p_\mu\right)}_{=\delta_{\lambda,\mu}} = z_\mu\delta_{\lambda,\mu} \tag{13.83.26}$$

for any partitions λ and μ.

The Hall inner product $(\cdot,\cdot) : \Lambda_{\mathbb{Q}} \times \Lambda_{\mathbb{Q}} \to \mathbb{Q}$ is a bilinear form on $\Lambda_{\mathbb{Q}}$. Hence, according to Definition 3.1.1(b) (below), this inner product induces a $\mathbb{Q}$-bilinear form $(\cdot,\cdot)_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}} : (\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}})\times(\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}) \to \mathbb{Q}$. Similarly, the Hall inner product $(\cdot,\cdot) : \Lambda\times\Lambda \to \mathbb{Z}$ induces a $\mathbb{Z}$-bilinear form $(\cdot,\cdot)_{\Lambda\otimes_{\mathbb{Z}}\Lambda} : (\Lambda\otimes_{\mathbb{Z}}\Lambda)\times(\Lambda\otimes_{\mathbb{Z}}\Lambda)\to\mathbb{Z}$, and this latter $\mathbb{Z}$-bilinear form is clearly the restriction of the $\mathbb{Q}$-bilinear form $(\cdot,\cdot)_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}}$ to $\Lambda\otimes_{\mathbb{Z}}\Lambda$.

We shall now show that

$$(a * b, c) = (a\otimes b, \Delta_\times(c))_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}} \qquad \text{for all } a\in\Lambda_{\mathbb{Q}},\ b\in\Lambda_{\mathbb{Q}} \text{ and } c\in\Lambda_{\mathbb{Q}}. \tag{13.83.27}$$

Proof of (13.83.27): Let $a\in\Lambda_{\mathbb{Q}}$, $b\in\Lambda_{\mathbb{Q}}$ and $c\in\Lambda_{\mathbb{Q}}$. The equality (13.83.27) is clearly $\mathbb{Q}$-linear in each of a, b and c. Hence, in proving this equality, we can WLOG assume that a, b and c are elements of the basis $(p_\lambda)_{\lambda\in\operatorname{Par}}$ of the $\mathbb{Q}$-module $\Lambda_{\mathbb{Q}}$. Assume this. Thus, $a = p_\lambda$, $b = p_\mu$ and $c = p_\nu$ for some partitions λ, μ and ν; consider these partitions.

We have $\delta_{\lambda,\mu}z_\lambda = \delta_{\lambda,\mu}z_\mu$ (in fact, the two sides of this equality are equal when $\lambda=\mu$, and both vanish otherwise). Hence, $\underbrace{a}_{=p_\lambda} * \underbrace{b}_{=p_\mu} = p_\lambda * p_\mu = \underbrace{\delta_{\lambda,\mu}z_\lambda}_{=\delta_{\lambda,\mu}z_\mu} p_\lambda = \delta_{\lambda,\mu}z_\mu p_\lambda$, so that

$$\left(\underbrace{a*b}_{=\delta_{\lambda,\mu}z_\mu p_\lambda}, \underbrace{c}_{=p_\nu}\right) = \left(\delta_{\lambda,\mu}z_\mu p_\lambda, p_\nu\right) = \delta_{\lambda,\mu}z_\lambda \underbrace{(p_\lambda, p_\nu)}_{\substack{=z_\nu\delta_{\lambda,\nu} \\ \text{(by (13.83.26), applied} \\ \text{to } \nu \text{ instead of } \mu)}} = \delta_{\lambda,\mu}z_\lambda z_\nu\delta_{\lambda,\nu}.$$

On the other hand, $c = p_\nu$, so that

$$\Delta_\times(c) = \Delta_\times(p_\nu) = p_\nu\otimes p_\nu \qquad \text{(by (13.83.18), applied to } \nu \text{ instead of } \lambda\text{)},$$

and thus

$$\begin{aligned}\left(\underbrace{a}_{=p_\lambda}\otimes\underbrace{b}_{=p_\mu}, \underbrace{\Delta_\times(c)}_{=p_\nu\otimes p_\nu}\right)_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}} &= (p_\lambda\otimes p_\mu, p_\nu\otimes p_\nu)_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}} = \underbrace{(p_\lambda, p_\nu)}_{\substack{=z_\nu\delta_{\lambda,\nu} \\ \text{(by (13.83.26), applied} \\ \text{to } \nu \text{ instead of } \mu)}} \underbrace{(p_\mu, p_\nu)}_{\substack{=z_\nu\delta_{\mu,\nu} \\ \text{(by (13.83.26), applied} \\ \text{to } \mu \text{ and } \nu \text{ instead of } \lambda \text{ and } \mu)}} \\ &\qquad \left(\text{by the definition of the bilinear form } (\cdot,\cdot)_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}}\right) \\ &= z_\nu\delta_{\lambda,\nu}z_\nu\delta_{\mu,\nu}.\end{aligned}$$

The equality in question, (13.83.27), thus rewrites as $\delta_{\lambda,\mu}z_\lambda z_\nu\delta_{\lambda,\nu} = z_\nu\delta_{\lambda,\nu}z_\nu\delta_{\mu,\nu}$ (because $(a*b,c) = \delta_{\lambda,\mu}z_\lambda z_\nu\delta_{\lambda,\nu}$ and $(a\otimes b, \Delta_\times(c))_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}} = z_\nu\delta_{\lambda,\nu}z_\nu\delta_{\mu,\nu}$). But the latter equality is obvious (because both of its sides are z_ν^2 if $\lambda=\mu=\nu$, and vanish otherwise). Hence, (13.83.27) must hold as well.

Now that (13.83.27) is proven, let $f\in\Lambda$ and $g\in\Lambda$ be arbitrary. We can apply (13.83.1) to $\mathbf{k}=\mathbb{Q}$, $A=\Lambda_{\mathbb{Q}}$, $L=\operatorname{Par}$, $(u_\lambda)_{\lambda\in L} = (s_\lambda)_{\lambda\in\operatorname{Par}}$, $(v_\lambda)_{\lambda\in L} = (s_\lambda)_{\lambda\in\operatorname{Par}}$ and $a = f*g$ (because the basis $(s_\lambda)_{\lambda\in\operatorname{Par}}$ of $\Lambda_{\mathbb{Q}}$ is orthonormal with respect to the Hall inner product $(\cdot,\cdot)$, and thus dual to itself with respect to this product). As a result, we obtain

$$f*g=\sum_{\lambda\in\operatorname{Par}}\underbrace{(s_\lambda,f*g)}_{\substack{=(f*g,s_\lambda)\\ \text{(since the Hall inner product}\\ \text{is symmetric)}}}s_\lambda=\sum_{\lambda\in\operatorname{Par}}\underbrace{(f*g,s_\lambda)}_{\substack{=(f\otimes g,\Delta_\times(s_\lambda))_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}}\\ \text{(by (13.83.27))}}}s_\lambda=\sum_{\lambda\in\operatorname{Par}}(f\otimes g,\Delta_\times(s_\lambda))_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}}s_\lambda.$$

But every $\lambda\in\operatorname{Par}$ satisfies $\Delta_\times\left(\underbrace{s_\lambda}_{\in\Lambda}\right)\in\Delta_\times(\Lambda)\subset\Lambda\otimes_{\mathbb{Z}}\Lambda$ (by Exercise 2.9.4(b)) and thus

$$(f\otimes g,\Delta_\times(s_\lambda))_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}}=(f\otimes g,\Delta_\times(s_\lambda))_{\Lambda\otimes_{\mathbb{Z}}\Lambda}\in\mathbb{Z}.$$

Hence,

$$f*g=\sum_{\lambda\in\operatorname{Par}}\underbrace{(f\otimes g,\Delta_\times(s_\lambda))_{\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}}}_{\in\mathbb{Z}}s_\lambda\in\sum_{\lambda\in\operatorname{Par}}\mathbb{Z}s_\lambda\subset\Lambda.$$

This solves Exercise 2.9.4(h).

(i) Define a map $U:\Lambda_{\mathbb{Q}}\to\mathbb{Q}$ by

$$U(f)=f(1)\qquad\text{for all }f\in\Lambda_{\mathbb{Q}}.$$

Notice that $U(f)=f(1)$ is the result of substituting $1,0,0,0,\ldots$ for $x_1,x_2,x_3,\ldots$ in f. Hence, U is a $\mathbb{Q}$-algebra homomorphism.

We shall now show that $\epsilon_1=U$.

For every integer $n\geq1$, we have

$$\begin{aligned}U(p_n)&=p_n(1)\qquad\text{(by the definition of }U)\\&=(\text{the result of substituting }1,0,0,0,\ldots\text{ for }x_1,x_2,x_3,\ldots\text{ in }p_n)\\&\qquad\text{(by the definition of }p_n(1))\\&=(\text{the result of substituting }1,0,0,0,\ldots\text{ for }x_1,x_2,x_3,\ldots\text{ in }x_1^n+x_2^n+x_3^n+x_4^n+\cdots)\\&\qquad(\text{since }p_n=x_1^n+x_2^n+x_3^n+x_4^n+\cdots)\\&=1^n+0^n+0^n+0^n+\cdots=1+0+0+0+\cdots=1\\&=\epsilon_1(p_n)\qquad(\text{since }\epsilon_1(p_n)=1\text{ (by the definition of }\epsilon_1)).\end{aligned}$$

In other words, the two $\mathbb{Q}$-algebra homomorphisms U and ϵ_1 are equal to each other on each element of the family $(p_n)_{n\geq1}$. But since this family $(p_n)_{n\geq1}$ is a generating set of the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$, this yields that the two $\mathbb{Q}$-algebra homomorphisms U and ϵ_1 must be identical (because if two $\mathbb{Q}$-algebra homomorphisms are equal to each other on each element of a generating set of their domain, then they must be identical). That is, $\epsilon_1=U$. Hence, every $f\in\Lambda_{\mathbb{Q}}$ satisfies $\epsilon_1(f)=U(f)=f(1)$ (by the definition of U). This solves Exercise 2.9.4(i).

13.84. **Solution to Exercise 2.9.6.** *Solution to Exercise 2.9.6.* We are going to be brief; more detailed proofs for everything except of the (very easy) equivalence $\mathcal{D}\iff\mathcal{J}$ can be found at http://www.cip.ifi.lmu.de/~grinberg/algebra/witt5f.pdf (along with generalizations and additional equivalences in the case of $A=\mathbb{Z}$).

As suggested by the hint, we first prove some elementary facts of number theory:

- Every positive integer n satisfies

(13.84.1)
$$\sum_{d\mid n}\phi(d)=n.$$

Proof: Let n be a positive integer. For every positive divisor d of n, there is a bijection

$$\{i\in\{1,2,\ldots,n\}\ \mid\ \gcd(i,n)=d\}\to\left\{j\in\left\{1,2,\ldots,\frac{n}{d}\right\}\ \mid\ j\text{ is coprime to }\frac{n}{d}\right\},$$
$$i\mapsto\frac{i}{d}.$$

Hence, for every positive divisor d of n, we have

$$\begin{aligned} \left|\left\{i \in \{1,2,\ldots,n\} \mid \gcd(i,n) = d\right\}\right| &= \left|\left\{j \in \left\{1,2,\ldots,\frac{n}{d}\right\} \mid j \text{ is coprime to } \frac{n}{d}\right\}\right| \\ &= \phi\left(\frac{n}{d}\right) \qquad \left(\text{because this is how } \phi\left(\frac{n}{d}\right) \text{ was defined}\right). \end{aligned} \tag{13.84.2}$$

Now,

$$n = \left|\{1,2,\ldots,n\}\right| = \sum_{d\mid n} \underbrace{\left|\left\{i \in \{1,2,\ldots,n\} \mid \gcd(i,n) = d\right\}\right|}_{=\phi\left(\frac{n}{d}\right)} = \sum_{d\mid n} \phi\left(\frac{n}{d}\right) = \sum_{d\mid n} \phi(d)$$

(here, we have substituted d for $\frac{n}{d}$ in the sum). This proves (13.84.1).

- Every positive integer n satisfies

$$\sum_{d\mid n} \mu(d) = \delta_{n,1}. \tag{13.84.3}$$

Proof: Let n be a positive integer. Let $n = p_1^{a_1} p_2^{a_2} \cdots p_k^{a_k}$ be the prime factorization of n, with all of $a_1, a_2, \ldots, a_k$ being positive integers (and with $p_1, p_2, \ldots, p_k$ being distinct primes). Then, the **squarefree** positive divisors of n all have the form $\prod_{i\in I} p_i$ for some subset I of $\{1,2,\ldots,k\}$. More precisely, there exists a bijection

$$\begin{aligned} \{I \subset \{1,2,\ldots,k\}\} &\to (\text{the set of all squarefree positive divisors of } n), \\ I &\mapsto \prod_{i\in I} p_i. \end{aligned} \tag{13.84.4}$$

Now, each positive divisor d of n is either squarefree or not. Hence,

$$\begin{aligned} \sum_{d\mid n} \mu(d) &= \sum_{\substack{d\mid n;\\ d \text{ is squarefree}}} \mu(d) + \sum_{\substack{d\mid n;\\ d \text{ is not squarefree}}} \underbrace{\mu(d)}_{\substack{=0\\ \text{(by the definition}\\ \text{of } \mu)}} = \sum_{\substack{d\mid n;\\ d \text{ is squarefree}}} \mu(d) \\ &= \sum_{I\subset\{1,2,\ldots,k\}} \underbrace{\mu\left(\prod_{i\in I} p_i\right)}_{\substack{=(-1)^{|I|}\\ \text{(since } \prod_{i\in I} p_i \text{ is squarefree}\\ \text{and has } |I| \text{ prime factors)}}} \\ &\qquad \left(\begin{array}{c}\text{here, we have substituted } \prod_{i\in I} p_i \text{ for } d\\ \text{due to the bijection (13.84.4)}\end{array}\right) \\ &= \sum_{I\subset\{1,2,\ldots,k\}} (-1)^{|I|} = \begin{cases} 1, & \text{if } \{1,2,\ldots,k\} = \varnothing; \\ 0, & \text{otherwise} \end{cases} = \begin{cases} 1, & \text{if } k = 0; \\ 0, & \text{otherwise} \end{cases} \\ &= \begin{cases} 1, & \text{if } n = 1; \\ 0, & \text{otherwise} \end{cases} \qquad \left(\begin{array}{c}\text{since } k \text{ is the number of distinct prime factors of } n,\\ \text{and thus we have } k = 0 \text{ if and only if } n = 1\end{array}\right) \\ &= \delta_{n,1}, \end{aligned}$$

which proves (13.84.3).

- Every positive integer n satisfies

$$\sum_{d\mid n} \mu(d) \frac{n}{d} = \phi(n). \tag{13.84.5}$$

Proof: This is an elementary fact, but we have a hammer at our disposal, and this looks conspicuously like a nail. Let us define a $\mathbb{Z}$-coalgebra. Namely, let $\mathbf{T}$ be the free $\mathbb{Z}$-module with basis

$(t_n)_{n\geq 1}$. We define a $\mathbb{Z}$-coalgebra structure on $\mathbf{T}$ by setting

$$\Delta(t_n) = \sum_{\substack{d,e\in\{1,2,3,\ldots\};\\ de=n}} t_d \otimes t_e = \sum_{d\mid n} t_d \otimes t_{n/d} \qquad \text{and} \qquad \epsilon(t_n) = \delta_{n,1}$$

for every $n \in \{1,2,3,\ldots\}$. It is straightforward to check that this makes $\mathbf{T}$ into a cocommutative coalgebra. Hence, $(\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z}), \star)$ is a $\mathbb{Z}$-algebra with unity ϵ. [665] This algebra $(\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z}), \star)$ is commutative[666]. We define four elements of $\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z})$:

- a $\mathbb{Z}$-linear map $\widetilde{\phi} : \mathbf{T} \to \mathbb{Z}$ which sends t_n to $\phi(n)$ for every $n \geq 1$;
- a $\mathbb{Z}$-linear map $\widetilde{\mu} : \mathbf{T} \to \mathbb{Z}$ which sends t_n to $\mu(n)$ for every $n \geq 1$;
- a $\mathbb{Z}$-linear map $\widetilde{\operatorname{id}} : \mathbf{T} \to \mathbb{Z}$ which sends t_n to n for every $n \geq 1$;
- a $\mathbb{Z}$-linear map $\widetilde{\mathbf{1}} : \mathbf{T} \to \mathbb{Z}$ which sends t_n to 1 for every $n \geq 1$.

Then, the identity that we want to prove – i.e., the identity (13.84.5) – is equivalent to the claim that $\widetilde{\mu} \star \widetilde{\operatorname{id}} = \widetilde{\phi}$. [667] Similarly, the (already proven) identity (13.84.1) is equivalent to $\widetilde{\phi} \star \widetilde{\mathbf{1}} = \widetilde{\operatorname{id}}$, and the (already proven) identity (13.84.3) is equivalent to $\widetilde{\mu} \star \widetilde{\mathbf{1}} = \epsilon$. Thus,

$$\begin{aligned}\widetilde{\mu} \star \underbrace{\widetilde{\operatorname{id}}}_{=\widetilde{\phi}\star\widetilde{\mathbf{1}}} &= \widetilde{\mu} \star \widetilde{\phi} \star \widetilde{\mathbf{1}} = \underbrace{\widetilde{\mu} \star \widetilde{\mathbf{1}}}_{=\epsilon} \star \widetilde{\phi} \qquad \left(\text{since } (\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z}), \star) \text{ is commutative}\right) \\ &= \epsilon \star \widetilde{\phi} = \widetilde{\phi}.\end{aligned}$$

As we know, this is equivalent to (13.84.5), so that (13.84.5) is proven.

It was not really necessary to phrase this argument in terms of coalgebras; this was only done to illustrate a use of the latter. Our proof can just as well be rewritten as a manipulation of sums, or (as a compromise between concreteness and structure) it can be paraphrased by using the *Dirichlet convolution*, which is the operation taking two maps $f, g : \{1,2,3,\ldots\} \to \mathbb{Z}$ to a third map $h : \{1,2,3,\ldots\} \to \mathbb{Z}$ defined by $h(n) = \sum_{d\mid n} f(d)\, g\left(\dfrac{n}{d}\right)$. Of course, this Dirichlet convolution is the same as our convolution $\star$ on $\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z})$, with the only difference that $\mathbb{Z}$-linear maps $\mathbf{T} \to \mathbb{Z}$ are replaced by arbitrary maps $\{1,2,3,\ldots\} \to \mathbb{Z}$.

- Every positive integer n satisfies

$$\sum_{d\mid n} d\mu(d)\, \phi\left(\frac{n}{d}\right) = \mu(n). \tag{13.84.6}$$

Proof: We use the setup we prepared in the proof of (13.84.5). Additionally, we define $\widetilde{\mu'} : \mathbf{T} \to \mathbb{Z}$ as the $\mathbb{Z}$-linear map which sends t_n to $n\mu(n)$ for every $n \geq 1$. Then, $\widetilde{\mu'} \star \widetilde{\operatorname{id}} = \epsilon$, because every positive integer n satisfies

$$\left(\widetilde{\mu'} \star \widetilde{\operatorname{id}}\right)(t_n) = \sum_{d\mid n} d\mu(d)\, \frac{n}{d} = \sum_{d\mid n} n\mu(d) = n \underbrace{\sum_{d\mid n} \mu(d)}_{\substack{=\delta_{n,1} \\ \text{(by (13.84.3))}}} = n\delta_{n,1} = \delta_{n,1} = \epsilon(t_n).$$

But recall that $\widetilde{\phi} = \widetilde{\mu} \star \widetilde{\operatorname{id}} = \widetilde{\operatorname{id}} \star \widetilde{\mu}$ (since $(\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z}), \star)$ is commutative), and thus

$$\widetilde{\mu'} \star \underbrace{\widetilde{\phi}}_{=\widetilde{\operatorname{id}}\star\widetilde{\mu}} = \underbrace{\widetilde{\mu'} \star \widetilde{\operatorname{id}}}_{=\epsilon} \star \widetilde{\mu} = \epsilon \star \widetilde{\mu} = \widetilde{\mu}.$$

[665] Number theorists will recognize this $\mathbb{Z}$-algebra as an isomorphic version of the so-called *algebra of formal Dirichlet series over* $\mathbb{Z}$. The isomorphism from $(\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z}), \star)$ to the algebra of formal Dirichlet series over $\mathbb{Z}$ takes an element $f \in (\operatorname{Hom}_{\mathbb{Z}}(\mathbf{T},\mathbb{Z}), \star)$ to the formal Dirichlet series $\sum_{n=1}^{\infty} f(n)\, n^{-s}$.

[666] This follows from Exercise 1.5.5 (applied to $\mathbb{Z}$, $\mathbf{T}$ and $\mathbb{Z}$ instead of $\mathbf{k}$, C and A).

[667] This is because the left hand side of (13.84.5) equals $\sum_{d\mid n} \widetilde{\mu}(t_d)\, \widetilde{\operatorname{id}}(t_{n/d}) = m\left(\left(\widetilde{\mu} \otimes \widetilde{\operatorname{id}}\right)\underbrace{\left(\sum_{d\mid n} t_d \otimes t_{n/d}\right)}_{=\Delta(t_n)}\right) = m\left(\left(\widetilde{\mu} \otimes \widetilde{\operatorname{id}}\right)(\Delta(t_n))\right) = \left(\widetilde{\mu} \star \widetilde{\operatorname{id}}\right)(t_n)$, whereas the right hand side equals $\widetilde{\phi}(t_n)$.

This is easily seen to be equivalent to (13.84.6), and so (13.84.6) is proven.

- If k is a positive integer, and if $p \in \mathbb{N}$, $a \in A$ and $b \in A$ are such that $a \equiv b \operatorname{mod} p^k A$, then

$$a^{p^\ell} \equiv b^{p^\ell} \operatorname{mod} p^{k+\ell} A \qquad \text{for every } \ell \in \mathbb{N}. \tag{13.84.7}$$

Proof: Let k be a positive integer. Let $p \in \mathbb{N}$, $a \in A$ and $b \in A$ be such that $a \equiv b \operatorname{mod} p^k A$. We need to prove (13.84.7). It is clearly enough to show that $a^p \equiv b^p \operatorname{mod} p^{k+1} A$, because then (13.84.7) will follow by induction over ℓ. But we have $a \equiv b \operatorname{mod} pA$ (since $a \equiv b \operatorname{mod} p^k A$ and since k is positive) and therefore

$$\begin{aligned} a^{p-1} + a^{p-2} b + \cdots + b^{p-1} &\equiv b^{p-1} + b^{p-2} b + \cdots + b^{p-1} \\ &= \underbrace{b^{p-1} + b^{p-1} + \cdots + b^{p-1}}_{p \text{ terms}} = p b^{p-1} \equiv 0 \operatorname{mod} pA, \end{aligned}$$

so that $a^{p-1} + a^{p-2} b + \cdots + b^{p-1} \in pA$. Thus,

$$a^p - b^p = \underbrace{(a-b)}_{\substack{\in p^k A \\ (\text{since } a \equiv b \operatorname{mod} p^k A)}} \underbrace{\left(a^{p-1} + a^{p-2} b + \cdots + b^{p-1}\right)}_{\in pA} \in \left(p^k A\right)(pA) = p^{k+1} A,$$

so that $a^p \equiv b^p \operatorname{mod} p^{k+1} A$. This proves (13.84.7).

- Here is a slightly more useful corollary of (13.84.7): If a prime number p and two elements a and b of A are such that $a \equiv b \operatorname{mod} pA$, then

$$a^N \equiv b^N \operatorname{mod} p^{v_p(N)+1} A \qquad \text{for every } N \in \{1, 2, 3, \ldots\}. \tag{13.84.8}$$

Proof: Let p be a prime number, and let a and b be two elements of A such that $a \equiv b \operatorname{mod} pA$. Let $N \in \{1, 2, 3, \ldots\}$. Write N in the form $N = p^{v_p(N)} M$ for some positive integer M. Then, (13.84.7) (applied to $\ell = v_p(N)$ and $k = 1$) yields $a^{p^{v_p(N)}} \equiv b^{p^{v_p(N)}} \operatorname{mod} p^{v_p(N)+1} A$, and because of $N = p^{v_p(N)} M$ we have

$$\begin{aligned} a^N &= a^{p^{v_p(N)} M} = \left(a^{p^{v_p(N)}}\right)^M \equiv \left(b^{p^{v_p(N)}}\right)^M \qquad \left(\text{since } a^{p^{v_p(N)}} \equiv b^{p^{v_p(N)}} \operatorname{mod} p^{v_p(N)+1} A\right) \\ &= b^{p^{v_p(N)} M} = b^N \operatorname{mod} p^{v_p(N)+1} A \qquad \left(\text{since } p^{v_p(N)} M = N\right). \end{aligned}$$

This proves (13.84.8).

We shall also use a fact from commutative algebra – namely, one of the versions of the Chinese Remainder Theorem of ring theory:

Theorem 13.84.1. *Let A be a commutative ring. Let $\mathbf{S}$ be a finite set. For every $s \in \mathbf{S}$, let I_s be an ideal of A. Assume that the ideals I_s of A are* comaximal[668]*; this means that every two distinct elements s and t of $\mathbf{S}$ satisfy $I_s + I_t = A$. Then:*

(a) *We have*

$$\bigcap_{s \in \mathbf{S}} I_s = \prod_{s \in \mathbf{S}} I_s.$$

(b) *The canonical ring homomorphism*

$$A / \left(\bigcap_{s \in \mathbf{S}} I_s\right) \to \prod_{s \in \mathbf{S}} (A / I_s), \qquad a + \bigcap_{s \in \mathbf{S}} I_s \mapsto (a + I_s)_{s \in \mathbf{S}}$$

is well-defined and a ring isomorphism.

See http://stacks.math.columbia.edu/tag/00DT (Lemma 10.14.4 (1) in the Stacks Project, as of 4 April 2020) or many other sources for a proof of Theorem 13.84.1. We shall only use part (a) of this theorem.

As a consequence of Theorem 13.84.1(a), we have the following:

[668] Some authors use the word "coprime" instead of "comaximal" here.

- If n is a positive integer and if A is a commutative ring, then

$$\bigcap_{\substack{p \text{ is a prime} \\ \text{factor of } n}} p^{v_p(n)} A = \prod_{\substack{p \text{ is a prime} \\ \text{factor of } n}} \left(p^{v_p(n)} A\right). \tag{13.84.9}$$

Indeed, this follows from Theorem 13.84.1(a), since the ideals $p^{v_p(n)}A$ of A (for varying p) are comaximal (because for any two distinct primes p and q, we can find integers x and y satisfying $p^{v_p(n)}x + q^{v_q(n)}y = 1$, and therefore we have $p^{v_p(n)}A + q^{v_q(n)}A = A$).

Now, we can step to proving the actual equivalences.

Proof of the implication $\mathcal{D} \Longrightarrow \mathcal{J}$: Assume that Assertion $\mathcal{D}$ holds. That is, there exists a family $(\alpha_n)_{n\geq 1} \in A^{\{1,2,3,\ldots\}}$ of elements of A such that every positive integer n satisfies $b_n = \sum_{d|n} d\alpha_d^{n/d}$. Consider this family $(\alpha_n)_{n\geq 1}$. Consider also the family $(w_n)_{n\geq 1} \in \Lambda_{\mathbb{Z}}^{\{1,2,3,\ldots\}}$ defined in Exercise 2.9.3(a). This family $(w_n)_{n\geq 1}$ is an algebraically independent generating set of $\Lambda_{\mathbb{Z}}$ (indeed, this is a restatement of Exercise 2.9.3(d)). Hence, there exists a unique $\mathbb{Z}$-algebra homomorphism $f : \Lambda_{\mathbb{Z}} \to A$ which satisfies

$$f(w_n) = \alpha_n \qquad \text{for every } n \in \{1, 2, 3, \ldots\}.$$

Consider this f. We have $p_n = \sum_{d|n} dw_d^{n/d}$ for every positive integer n (by Exercise 2.9.3(e)). Thus, for every positive integer n, we have

$$f(p_n) = f\left(\sum_{d|n} dw_d^{n/d}\right) = \sum_{d|n} d\left(\underbrace{f(w_d)}_{=\alpha_d}\right)^{n/d} \qquad \text{(since } f \text{ is a } \mathbb{Z}\text{-algebra homomorphism)}$$
$$= \sum_{d|n} d\alpha_d^{n/d} = b_n.$$

Hence, there exists a ring homomorphism $\Lambda_{\mathbb{Z}} \to A$ which, for every positive integer n, sends p_n to b_n (namely, f). That is, Assertion $\mathcal{J}$ holds, and the implication $\mathcal{D} \Longrightarrow \mathcal{J}$ is proven.

Proof of the implication $\mathcal{J} \Longrightarrow \mathcal{D}$: Assume that Assertion $\mathcal{J}$ holds. That is, there exists a ring homomorphism $\Lambda_{\mathbb{Z}} \to A$ which, for every positive integer n, sends p_n to b_n. Let f be such a homomorphism. Consider the family $(w_n)_{n\geq 1} \in \Lambda_{\mathbb{Z}}^{\{1,2,3,\ldots\}}$ defined in Exercise 2.9.3(a). For every positive integer n, we have $p_n = \sum_{d|n} dw_d^{n/d}$ (by Exercise 2.9.3(e)) and thus

$$f(p_n) = f\left(\sum_{d|n} dw_d^{n/d}\right) = \sum_{d|n} d\left(f(w_d)\right)^{n/d} \qquad \text{(since } f \text{ is a ring homomorphism)}.$$

Since $f(p_n) = b_n$ (by the definition of f), this rewrites as $b_n = \sum_{d|n} d\left(f(w_d)\right)^{n/d}$. Thus, there exists a family $(\alpha_n)_{n\geq 1} \in A^{\{1,2,3,\ldots\}}$ of elements of A such that every positive integer n satisfies $b_n = \sum_{d|n} d\alpha_d^{n/d}$ (namely, such a family can be defined by $\alpha_n = f(w_n)$). Assertion $\mathcal{D}$ thus holds. We have now proven the implication $\mathcal{J} \Longrightarrow \mathcal{D}$.

Proof of the implication $\mathcal{D} \Longrightarrow \mathcal{C}$: Assume that Assertion $\mathcal{D}$ holds. That is, there exists a family $(\alpha_n)_{n\geq 1} \in A^{\{1,2,3,\ldots\}}$ of elements of A such that every positive integer n satisfies $b_n = \sum_{d|n} d\alpha_d^{n/d}$. Consider this family $(\alpha_n)_{n\geq 1}$.

We need to prove that Assertion $\mathcal{C}$ holds, i.e., that we have

$$\varphi_p\left(b_{n/p}\right) \equiv b_n \mod p^{v_p(n)}A \tag{13.84.10}$$

for every positive integer n and every prime factor p of n. So let us fix a positive integer n and a prime factor p of n. We need to prove (13.84.10).

The definition of the family $(\alpha_n)_{n\geq 1}$ shows that $b_{n/p} = \sum_{d|n/p} d\alpha_d^{(n/p)/d}$, so that

$$\varphi_p\left(b_{n/p}\right) = \varphi_p\left(\sum_{d|n/p} d\alpha_d^{(n/p)/d}\right) = \sum_{d|n/p} d\left(\varphi_p\left(\alpha_d\right)\right)^{(n/p)/d} \qquad \text{(since } \varphi_p \text{ is a ring endomorphism)}.$$

On the other hand,

$$\sum_{d\mid n} d\alpha_d^{n/d} = \sum_{d\mid n/p} d\alpha_d^{n/d} + \sum_{\substack{d\mid n;\\ d\nmid n/p}} \underbrace{d}_{\substack{\equiv 0 \bmod p^{v_p(n)}A \\ \text{(since } d\mid n \text{ and } d\nmid n/p \\ \text{yield } p^{v_p(n)}\mid d)}} \alpha_d^{n/d} \equiv \sum_{d\mid n/p} d\alpha_d^{n/d} \bmod p^{v_p(n)}A. \tag{13.84.11}$$

Thus, if we succeed to prove that

$$d\left(\varphi_p\left(\alpha_d\right)\right)^{(n/p)/d} \equiv d\alpha_d^{n/d} \bmod p^{v_p(n)}A \qquad \text{for every } d \mid n/p, \tag{13.84.12}$$

then we will obtain

$$\begin{aligned} \varphi_p\left(b_{n/p}\right) &= \sum_{d\mid n/p} \underbrace{d\left(\varphi_p\left(\alpha_d\right)\right)^{(n/p)/d}}_{\equiv d\alpha_d^{n/d} \bmod p^{v_p(n)}A} \equiv \sum_{d\mid n/p} d\alpha_d^{n/d} \equiv \sum_{d\mid n} d\alpha_d^{n/d} \qquad (\text{by } (13.84.11)) \\ &= b_n \bmod p^{v_p(n)}A \qquad \left(\text{since } b_n = \sum_{d\mid n} d\alpha_d^{n/d}\right), \end{aligned}$$

and thus our goal (proving (13.84.10)) will be achieved. Hence, it remains to prove (13.84.12).

So let d be any positive divisor of n/p. Then, $\varphi_p\left(\alpha_d\right) \equiv \alpha_d^p \bmod pA$ (because of the axiom $\varphi_p(a) \equiv a^p \bmod pA$ for every $a \in A$). Thus, (13.84.8) (applied to $a = \varphi_p\left(\alpha_d\right)$, $b = \alpha_p^d$ and $N = (n/p)/d$) yields $\left(\varphi_p\left(\alpha_d\right)\right)^{(n/p)/d} \equiv \left(\alpha_d^p\right)^{(n/p)/d} \bmod p^{v_p((n/p)/d)+1}A$. Since $\left(\alpha_d^p\right)^{(n/p)/d} = \alpha_d^{n/d}$ and $v_p\left((n/p)/d\right)+1 = v_p(n/d)$, this rewrites as $\left(\varphi_p\left(\alpha_d\right)\right)^{(n/p)/d} \equiv \alpha_d^{n/d} \bmod p^{v_p(n/d)}A$. Multiplying this by d results in $d\left(\varphi_p\left(\alpha_d\right)\right)^{(n/p)/d} \equiv d\alpha_d^{n/d} \bmod dp^{v_p(n/d)}A$. Since $dp^{v_p(n/d)}$ is divisible by $p^{v_p(n)}$, this yields (13.84.12). This completes the proof of (13.84.12), and thus also that of the implication $\mathcal{D} \Longrightarrow \mathcal{C}$.

Proof of the implication $\mathcal{C} \Longrightarrow \mathcal{D}$*:* Assume that Assertion $\mathcal{C}$ holds. Thus, for every positive integer n and every prime factor p of n, we have

$$\varphi_p\left(b_{n/p}\right) \equiv b_n \bmod p^{v_p(n)}A. \tag{13.84.13}$$

We now need to prove that Assertion $\mathcal{D}$ holds as well. In other words, we need to show that there exists a family $\left(\alpha_n\right)_{n\geq 1} \in A^{\{1,2,3,\ldots\}}$ of elements of A such that every positive integer n satisfies $b_n = \sum_{d\mid n} d\alpha_d^{n/d}$. In other words (renaming n as m), we need to show that there exists a family $\left(\alpha_m\right)_{m\geq 1} \in A^{\{1,2,3,\ldots\}}$ of elements of A such that every positive integer m satisfies $b_m = \sum_{d\mid m} d\alpha_d^{m/d}$.

We construct this family $\left(\alpha_m\right)_{m\geq 1}$ recursively. So we fix some $n \geq 1$, and assume that α_m is already constructed for every positive integer $m < n$ in such a way that

$$\text{the equality } b_m = \sum_{d\mid m} d\alpha_d^{m/d} \text{ is satisfied for every positive integer } m < n. \tag{13.84.14}$$

We now need to construct an $\alpha_n \in A$ such that $b_m = \sum_{d\mid m} d\alpha_d^{m/d}$ is satisfied for $m = n$. In other words, we need to construct an $\alpha_n \in A$ satisfying $b_n = \sum_{d\mid n} d\alpha_d^{n/d}$.

Let us first choose α_n **arbitrarily** (with the intention to tweak it later). Let p be any prime factor of n. Then, applying (13.84.14) to $m = n/p$, we obtain $b_{n/p} = \sum_{d\mid n/p} d\alpha_d^{(n/p)/d}$. This allows us to prove that $\varphi_p\left(b_{n/p}\right) \equiv \sum_{d\mid n} d\alpha_d^{n/d} \bmod p^{v_p(n)}A$ holds (just as in the proof of the implication $\mathcal{D} \Longrightarrow \mathcal{C}$). Compared with (13.84.13), this yields $b_n \equiv \sum_{d\mid n} d\alpha_d^{n/d} \bmod p^{v_p(n)}A$. That is, $b_n - \sum_{d\mid n} d\alpha_d^{n/d} \in p^{v_p(n)}A$.

Now, let us forget that we fixed p. We thus have shown that (with our arbitrary choice of α_n) we have $b_n - \sum_{d|n} d\alpha_d^{n/d} \in p^{v_p(n)} A$ for every prime factor p of n. As a consequence,

$$b_n - \sum_{d|n} d\alpha_d^{n/d} \in \bigcap_{\substack{p \text{ is a prime} \\ \text{factor of } n}} p^{v_p(n)} A = \prod_{\substack{p \text{ is a prime} \\ \text{factor of } n}} \left(p^{v_p(n)} A\right) \qquad \text{(by (13.84.9))}$$
$$= \underbrace{\left(\prod_{\substack{p \text{ is a prime} \\ \text{factor of } n}} p^{v_p(n)} \right)}_{=n} A = nA.$$

In other words, there exists a $\gamma \in A$ such that $b_n - \sum_{d|n} d\alpha_d^{n/d} = n\gamma$. Consider this γ. Now, if we replace α_n by $\alpha_n + \gamma$, then the sum $\sum_{d|n} d\alpha_d^{n/d}$ increases by $n\gamma = b_n - \sum_{d|n} d\alpha_d^{n/d}$, and therefore becomes precisely b_n. Hence, by replacing α_n by $\alpha_n + \gamma$, we achieve that $b_n = \sum_{d|n} d\alpha_d^{n/d}$ holds. Thus, we have found the α_n we were searching for, and the recursive construction of the family $(\alpha_m)_{m \geq 1}$ has proceeded by one more step. The proof of the implication $\mathcal{C} \Longrightarrow \mathcal{D}$ is thus complete.

Proof of the implication $\mathcal{E} \Longrightarrow \mathcal{C}$: The proof of the implication $\mathcal{E} \Longrightarrow \mathcal{C}$ proceeds exactly as our above proof of the implication $\mathcal{D} \Longrightarrow \mathcal{C}$, with the following changes:

- Every appearance of α_i for some $i \geq 1$ must be replaced by the corresponding β_i.
- Every time an element of A was taken to the k-th power (for some $k \in \{1, 2, 3, \ldots\}$) in our proof of the implication $\mathcal{D} \Longrightarrow \mathcal{C}$, it needs now to be subjected to the ring endomorphism φ_k instead. So, for example, $\alpha_d^{n/d}$ is replaced by $\varphi_{n/d}(\beta_d)$ everywhere (remember that α_d becomes β_d). Note that this concerns only elements of A. We don't replace the power $p^{v_p(n)}$ by anything.
- The equality
$$\varphi_p \left(\sum_{d|n/p} d\alpha_d^{(n/p)/d} \right) = \sum_{d|n/p} d \left(\varphi_p(\alpha_d)\right)^{(n/p)/d}$$
is replaced by
$$\varphi_p \left(\sum_{d|n/p} d\varphi_{(n/p)/d}(\beta_d) \right) = \sum_{d|n/p} d\varphi_{(n/p)/d}(\varphi_p(\beta_d)),$$
whose proof uses the $\mathbb{Z}$-linearity of φ_p and the fact that $\varphi_p \circ \varphi_{(n/p)/d} = \varphi_{n/d} = \varphi_{(n/p)/d} \circ \varphi_p$.
- The proof of (13.84.12) needs to be replaced by a proof of the congruence

$$d\varphi_{(n/p)/d}(\varphi_p(\beta_d)) \equiv d\varphi_{n/d}(\beta_d) \mod p^{v_p(n)} A \qquad \text{for every } d \mid n/p. \tag{13.84.15}$$

Fortunately, the latter congruence is obvious, since $\varphi_{(n/p)/d} \circ \varphi_p = \varphi_{n/d}$.

Proof of the implication $\mathcal{C} \Longrightarrow \mathcal{E}$: The proof of the implication $\mathcal{C} \Longrightarrow \mathcal{E}$ can be obtained from the proof of the implication $\mathcal{C} \Longrightarrow \mathcal{D}$ using the same changes that were made to transform the proof of the implication $\mathcal{D} \Longrightarrow \mathcal{C}$ into a proof of the implication $\mathcal{E} \Longrightarrow \mathcal{C}$. The only new "idea" is to use the fact that $\varphi_1 = \text{id}$ (in showing that if we replace β_n by $\beta_n + \gamma$, then the sum $\sum_{d|n} d\varphi_{n/d}(\beta_d)$ increases by $n\gamma$).

Proof of the implication $\mathcal{E} \Longrightarrow \mathcal{F}$: Assume that Assertion $\mathcal{E}$ holds. That is, there exists a family $(\beta_n)_{n \geq 1} \in A^{\{1,2,3,\ldots\}}$ of elements of A such that every positive integer n satisfies

$$b_n = \sum_{d|n} d\varphi_{n/d}(\beta_d). \tag{13.84.16}$$

Consider this family $(\beta_n)_{n \geq 1}$. We need to prove that Assertion $\mathcal{F}$ holds, i.e., that every positive integer n satisfies

$$\sum_{d|n} \mu(d) \varphi_d(b_{n/d}) \in nA.$$

We fix a positive integer n. Then, every positive divisor d of n satisfies $b_{n/d} = \sum_{e \mid n/d} e\varphi_{(n/d)/e}(\beta_e)$ (by (13.84.16), applied to n/d instead of n, and with the summation index d renamed as e). Hence,

$$\begin{aligned}
\sum_{d \mid n} \mu(d)\, \varphi_d \left(\underbrace{b_{n/d}}_{= \sum_{e \mid n/d} e\varphi_{(n/d)/e}(\beta_e)} \right) &= \sum_{d \mid n} \mu(d)\, \varphi_d \left(\sum_{e \mid n/d} e\varphi_{(n/d)/e}(\beta_e) \right) \\
&= \sum_{d \mid n} \mu(d) \sum_{e \mid n/d} e\varphi_d\left(\varphi_{(n/d)/e}(\beta_e)\right) \qquad \text{(since } \varphi_d \text{ is linear)} \\
&= \underbrace{\sum_{d \mid n} \sum_{e \mid n/d}}_{= \sum_{e \mid n} \sum_{d \mid n/e}} \mu(d)\, e \underbrace{\varphi_d\left(\varphi_{(n/d)/e}(\beta_e)\right)}_{\substack{= \left(\varphi_d \circ \varphi_{(n/d)/e}\right)(\beta_e) \\ = \varphi_{n/e}(\beta_e)}} \\
&= \sum_{e \mid n} \underbrace{\sum_{d \mid n/e} \mu(d)}_{\substack{= \delta_{n/e,1} \\ \text{(by (13.84.3), applied} \\ \text{to } n/e \text{ instead of } n\text{)}}} e\varphi_{n/e}(\beta_e) = \sum_{e \mid n} \underbrace{\delta_{n/e,1}}_{= \delta_{e,n}} e\varphi_{n/e}(\beta_e) \\
&= \sum_{e \mid n} \delta_{e,n} e\varphi_{n/e}(\beta_e) = n \underbrace{\varphi_{n/n}}_{= \varphi_1 = \mathrm{id}} (\beta_n) = n\beta_n \in nA.
\end{aligned}$$

Thus, Assertion $\mathcal{F}$ holds, so that we have proven the implication $\mathcal{E} \Longrightarrow \mathcal{F}$.

Proof of the implication $\mathcal{F} \Longrightarrow \mathcal{E}$*:* Assume that Assertion $\mathcal{F}$ holds. That is, every positive integer n satisfies

$$\sum_{d \mid n} \mu(d)\, \varphi_d\left(b_{n/d}\right) \in nA. \tag{13.84.17}$$

Now we need to prove that Assertion $\mathcal{E}$ holds, i.e., that there exists a family $(\beta_n)_{n \geq 1} \in A^{\{1,2,3,\ldots\}}$ of elements of A such that every positive integer n satisfies

$$b_n = \sum_{d \mid n} d\varphi_{n/d}(\beta_d). \tag{13.84.18}$$

We shall construct such a family $(\beta_n)_{n \geq 1}$ recursively. That is, we fix some $N \in \{1, 2, 3, \ldots\}$, and we assume that we already have constructed a $\beta_n \in A$ for every positive integer $n < N$ in such a way that (13.84.18) is satisfied for every positive integer $n < N$. We now need to find a $\beta_N \in A$ such that (13.84.18) is satisfied for $n = N$ as well.

From (13.84.17) (applied to $n = N$), we have $\sum_{d\mid N} \mu(d)\, \varphi_d\left(b_{N/d}\right) \in nA$. Thus, there exists a $t \in A$ such that $\sum_{d\mid N} \mu(d)\, \varphi_d\left(b_{N/d}\right) = Nt$. Set Consider this t. Set $\beta_N = t$. We have

$$\begin{aligned}
Nt &= \sum_{d\mid N} \mu(d)\, \varphi_d\left(b_{N/d}\right) = \sum_{e\mid N} \mu(e)\, \varphi_e\left(b_{N/e}\right) = \sum_{\substack{e\mid N;\\ e>1}} \mu(e)\, \varphi_e\left(\underbrace{b_{N/e}}_{\substack{=\sum_{d\mid N/e} d\varphi_{(N/e)/d}(\beta_d) \\ \text{(by (13.84.18), applied} \\ \text{to } n=N/e, \text{ because } N/e<n)}}\right) + \underbrace{\mu(1)}_{=1}\underbrace{\varphi_1}_{=\operatorname{id}}\left(\underbrace{b_{N/1}}_{=b_N}\right) \\
&= \sum_{\substack{e\mid N;\\ e>1}} \mu(e)\, \varphi_e\left(\sum_{d\mid N/e} d\varphi_{(N/e)/d}\left(\beta_d\right)\right) + b_N \\
&= \sum_{\substack{e\mid N;\\ e>1}} \mu(e) \sum_{d\mid N/e} d\, \underbrace{\varphi_e\left(\varphi_{(N/e)/d}\left(\beta_d\right)\right)}_{\substack{=\left(\varphi_e\circ\varphi_{(N/e)/d}\right)(\beta_d) \\ =\varphi_{N/d}(\beta_d)}} + b_N \qquad \text{(since } \varphi_e \text{ is linear)} \\
&= \sum_{\substack{e\mid N;\\ e>1}} \mu(e) \sum_{d\mid N/e} d\varphi_{N/d}\left(\beta_d\right) + b_N = \underbrace{\sum_{\substack{e\mid N;\\ e>1}} \sum_{d\mid N/e}}_{= \sum_{\substack{d\mid N;\\ d<N}} \sum_{\substack{e\mid N/d;\\ e>1}}} \mu(e)\, d\varphi_{N/d}\left(\beta_d\right) + b_N \\
&= \sum_{\substack{d\mid N;\\ d<N}} \underbrace{\sum_{\substack{e\mid N/d;\\ e>1}} \mu(e)}_{\substack{=\sum_{e\mid N/d}\mu(e)-\mu(1) \\ \text{(since } 1\mid N/d)}} d\varphi_{N/d}\left(\beta_d\right) + b_N = \sum_{\substack{d\mid N;\\ d<N}} \left(\underbrace{\sum_{e\mid N/d} \mu(e)}_{\substack{=\delta_{N/d,1} \\ \text{(by (13.84.3), applied} \\ \text{to } N/d \text{ instead of } n)}} - \underbrace{\mu(1)}_{=1}\right) d\varphi_{N/d}\left(\beta_d\right) + b_N \\
&= \sum_{\substack{d\mid N;\\ d<N}} \left(\underbrace{\delta_{N/d,1}}_{\substack{=0 \\ \text{(since } N/d>1)}} -1\right) d\varphi_{N/d}\left(\beta_d\right) + b_N = \sum_{\substack{d\mid N;\\ d<N}} (-1)\, d\varphi_{N/d}\left(\beta_d\right) + b_N \\
&= -\sum_{\substack{d\mid N;\\ d<N}} d\varphi_{N/d}\left(\beta_d\right) + b_N .
\end{aligned} \tag{13.84.19}$$

Now,

$$\begin{aligned}
\sum_{d\mid N} d\varphi_{N/d}\left(\beta_d\right) &= \sum_{\substack{d\mid N;\\ d<N}} d\varphi_{N/d}\left(\beta_d\right) + N \underbrace{\varphi_{N/N}}_{=\varphi_1=\operatorname{id}}\left(\underbrace{\beta_N}_{=t}\right) = \sum_{\substack{d\mid N;\\ d<N}} d\varphi_{N/d}\left(\beta_d\right) + \underbrace{Nt}_{\substack{=-\sum_{\substack{d\mid N;\\ d<N}} d\varphi_{N/d}(\beta_d)+b_N \\ \text{(by (13.84.19))}}} \\
&= \sum_{\substack{d\mid N;\\ d<N}} d\varphi_{N/d}\left(\beta_d\right) + \left(-\sum_{\substack{d\mid N;\\ d<N}} d\varphi_{N/d}\left(\beta_d\right) + b_N\right) = b_N .
\end{aligned}$$

Thus, (13.84.18) is satisfied for $n = N$. We have thus completed a step of our recursive construction of the family $\left(\beta_n\right)_{n\geq 1}$; this family therefore exists, and the implication $\mathcal{F} \Longrightarrow \mathcal{E}$ is proven.

Proof of the implication $\mathcal{F} \Longrightarrow \mathcal{G}$: Assume that Assertion $\mathcal{F}$ holds. That is, every positive integer n satisfies

$$\sum_{d\mid n} \mu(d)\,\varphi_d\left(b_{n/d}\right) \in nA. \tag{13.84.20}$$

On the other hand, every positive integer e satisfies

$$\sum_{d\mid e} \mu(d)\,\frac{e}{d} = \phi(e) \tag{13.84.21}$$

(by (13.84.3), applied to $n = e$). Now, every positive integer n satisfies

$$\begin{aligned}
\sum_{d\mid n} \phi(d)\,\varphi_d\left(b_{n/d}\right) &= \sum_{e\mid n} \underbrace{\phi(e)}_{\substack{=\sum_{d\mid e}\mu(d)\frac{e}{d} \\ \text{(by (13.84.21))}}} \varphi_e\left(b_{n/e}\right) \\
&= \underbrace{\sum_{e\mid n}\sum_{d\mid e}}_{=\sum_{d\mid n}\sum_{\substack{e\mid n;\\ d\mid e}}} \mu(d)\,\frac{e}{d}\varphi_e\left(\underbrace{b_{n/e}}_{=b_{(n/d)/(e/d)}}\right) = \sum_{d\mid n}\sum_{\substack{e\mid n;\\ d\mid e}} \mu(d)\,\frac{e}{d}\varphi_e\left(b_{(n/d)/(e/d)}\right) \\
&= \underbrace{\sum_{d\mid n}\sum_{e\mid n/d}}_{=\sum_{e\mid n}\sum_{d\mid n/e}} \mu(d)\,e\,\underbrace{\varphi_{ed}}_{=\varphi_e\circ\varphi_d}\left(\underbrace{b_{(n/d)/e}}_{=b_{(n/e)/d}}\right) \qquad \text{(here, we have substituted } ed \text{ for } e \text{ in the second sum)} \\
&= \sum_{e\mid n}\sum_{d\mid n/e} \mu(d)\,e\left(\varphi_e\circ\varphi_d\right)\left(b_{(n/e)/d}\right) = \sum_{e\mid n}\sum_{d\mid n/e} \mu(d)\,e\varphi_e\left(\varphi_d\left(b_{(n/e)/d}\right)\right) \\
&= \sum_{e\mid n} e \sum_{d\mid n/e} \mu(d)\,\varphi_e\left(\varphi_d\left(b_{(n/e)/d}\right)\right) = \sum_{e\mid n} e\varphi_e\underbrace{\left(\sum_{d\mid n/e}\mu(d)\,\varphi_d\left(b_{(n/e)/d}\right)\right)}_{\substack{\in(n/e)A \\ \text{(by (13.84.20), applied} \\ \text{to } n/e \text{ instead of } n)}} \qquad \text{(since } \varphi_e \text{ is } \mathbb{Z}\text{-linear)} \\
&\in \sum_{e\mid n} e \underbrace{\varphi_e\left((n/e)\,A\right)}_{\substack{\subset(n/e)A \\ \text{(since } \varphi_e \text{ is } \mathbb{Z}\text{-linear)}}} \subset \sum_{e\mid n} \underbrace{e\,(n/e)}_{=n} A = \sum_{e\mid n} nA \subset nA.
\end{aligned}$$

Thus, Assertion $\mathcal{G}$ holds. We have thus proven the implication $\mathcal{F} \Longrightarrow \mathcal{G}$.

Proof of the implication $\mathcal{G} \Longrightarrow \mathcal{F}$: Assume that Assertion $\mathcal{G}$ holds. That is, every positive integer n satisfies

$$\sum_{d\mid n} \phi(d)\,\varphi_d\left(b_{n/d}\right) \in nA. \tag{13.84.22}$$

On the other hand, every positive integer e satisfies $\sum_{d\mid e} d\mu(d)\,\phi\left(\frac{e}{d}\right) = \mu(e)$ (by (13.84.6), applied to $n = e$). In other words, every positive integer e satisfies

$$\mu(e) = \sum_{d\mid e} d\mu(d)\,\phi\left(\frac{e}{d}\right) = \sum_{d\mid e} \frac{e}{d}\mu\left(\frac{e}{d}\right)\phi(d) \tag{13.84.23}$$

(here, we have substituted e/d for d in the sum). Now, every positive integer n satisfies

$$\sum_{d|n} \mu(d)\varphi_d\left(b_{n/d}\right) = \sum_{e|n} \underbrace{\mu(e)}_{\substack{=\sum_{d|e}\frac{e}{d}\mu\left(\frac{e}{d}\right)\phi(d) \\ \text{(by (13.84.23))}}} \varphi_e\left(b_{n/e}\right)$$

$$= \underbrace{\sum_{e|n}\sum_{d|e}}_{=\sum_{d|n}\sum_{\substack{e|n;\\ d|e}}} \frac{e}{d}\mu\left(\frac{e}{d}\right)\phi(d)\varphi_e\left(\underbrace{b_{n/e}}_{=b_{(n/d)/(e/d)}}\right)$$

$$= \sum_{d|n}\sum_{\substack{e|n;\\ d|e}} \frac{e}{d}\mu\left(\frac{e}{d}\right)\phi(d)\varphi_e\left(b_{(n/d)/(e/d)}\right) = \underbrace{\sum_{d|n}\sum_{e|n/d}}_{=\sum_{e|n}\sum_{d|n/e}} e\mu(e)\phi(d)\underbrace{\varphi_{ed}}_{=\varphi_e\circ\varphi_d}\left(\underbrace{b_{(n/d)/e}}_{=b_{(n/e)/d}}\right)$$

(here, we have substituted ed for e in the second sum)

$$= \sum_{e|n}\sum_{d|n/e} e\mu(e)\phi(d)\left(\varphi_e\circ\varphi_d\right)\left(b_{(n/e)/d}\right) = \sum_{e|n}\sum_{d|n/e} e\mu(e)\phi(d)\varphi_e\left(\varphi_d\left(b_{(n/e)/d}\right)\right)$$

$$= \sum_{e|n} e\mu(e)\sum_{d|n/e}\phi(d)\varphi_e\left(\varphi_d\left(b_{(n/e)/d}\right)\right) = \sum_{e|n} e\mu(e)\varphi_e\underbrace{\left(\sum_{d|n/e}\phi(d)\varphi_d\left(b_{(n/e)/d}\right)\right)}_{\substack{\in(n/e)A \\ \text{(by (13.84.22), applied} \\ \text{to } n/e \text{ instead of } n)}} \qquad \text{(since } \varphi_e \text{ is } \mathbb{Z}\text{-linear)}$$

$$\in \sum_{e|n} e\mu(e)\underbrace{\varphi_e\left((n/e)A\right)}_{\substack{\subset(n/e)A \\ \text{(since } \varphi_e \text{ is } \mathbb{Z}\text{-linear)}}} \subset \sum_{e|n}\underbrace{e\mu(e)(n/e)}_{=n\mu(e)}A = \sum_{e|n} n\mu(e)A \subset nA.$$

Thus, Assertion $\mathcal{F}$ holds. We have thus proven the implication $\mathcal{G} \Longrightarrow \mathcal{F}$.

Proof of the equivalence $\mathcal{G} \Longleftrightarrow \mathcal{H}$*:* For every positive integer n, we have

$$\sum_{i=1}^{n}\varphi_{n/\gcd(i,n)}\left(b_{\gcd(i,n)}\right) = \sum_{d|n}\underbrace{\sum_{\substack{i\in\{1,2,\ldots,n\};\\ \gcd(i,n)=d}}\varphi_{n/d}\left(b_d\right)}_{\substack{=\phi\left(\frac{n}{d}\right)\varphi_{n/d}(b_d) \\ \text{(by (13.84.2))}}}$$

$$= \sum_{d|n}\phi\left(\frac{n}{d}\right)\varphi_{n/d}\left(b_d\right) = \sum_{d|n}\phi(d)\varphi_d\left(b_{n/d}\right)$$

(here, we have substituted n/d for d in the sum). This makes it clear that Assertions $\mathcal{G}$ and $\mathcal{H}$ are equivalent.

The implications and equivalences that we have proven, combined, yield the equivalence of all seven assertions $\mathcal{C}$, $\mathcal{D}$, $\mathcal{E}$, $\mathcal{F}$, $\mathcal{G}$, $\mathcal{H}$ and $\mathcal{J}$. This solves Exercise 2.9.6.

13.85. **Solution to Exercise 2.9.8.** *Solution to Exercise 2.9.8.* We know that the seven assertions $\mathcal{C}$, $\mathcal{D}$, $\mathcal{E}$, $\mathcal{F}$, $\mathcal{G}$, $\mathcal{H}$ and $\mathcal{J}$ are equivalent; hence, for each of our families, it suffices to prove one of these assertions. We choose the assertion $\mathcal{C}$, as it is the easiest to prove.

- *Proof of Assertion* $\mathcal{C}$ *for the family* $(b_n)_{n\geq 1} = (q^n)_{n\geq 1}$*, where* q *is a given integer:* Let q be an integer. We need to prove Assertion $\mathcal{C}$ for the family $(b_n)_{n\geq 1} = (q^n)_{n\geq 1}$. This means proving that for every positive integer n and every prime factor p of n, we have

$$\varphi_p\left(q^{n/p}\right) \equiv q^n \operatorname{mod} p^{v_p(n)}\mathbb{Z}. \tag{13.85.1}$$

So let us prove this. Let n be a positive integer, and let p be a prime factor of n. Fermat's little theorem yields $q^p \equiv q \operatorname{mod} p\mathbb{Z}$. Hence, (13.84.8) (applied to $A = \mathbb{Z}$, $a = q^p$, $b = q$ and $N = n/p$) yields $(q^p)^{n/p} \equiv q^{n/p} \operatorname{mod} p^{v_p(n/p)+1}\mathbb{Z}$. Since $(q^p)^{n/p} = q^n$ and $v_p(n/p) + 1 = v_p(n)$, this rewrites as $q^n \equiv q^{n/p} \operatorname{mod} p^{v_p(n)}\mathbb{Z}$. Now, $\varphi_p = \operatorname{id}$, so that $\varphi_p\left(q^{n/p}\right) = q^{n/p} \equiv q^n \operatorname{mod} p^{v_p(n)}\mathbb{Z}$. Thus, (13.85.1) is proven, and we are done with the family $(b_n)_{n\geq 1} = (q^n)_{n\geq 1}$.

- *Proof of Assertion $\mathcal{C}$ for the family $(b_n)_{n\geq 1} = (q)_{n\geq 1}$, where q is a given integer:* Let q be an integer. We need to prove Assertion $\mathcal{C}$ for the family $(b_n)_{n\geq 1} = (q)_{n\geq 1}$. This means proving that for every positive integer n and every prime factor p of n, we have
$$\varphi_p(q) \equiv q \operatorname{mod} p^{v_p(n)}\mathbb{Z}.$$
But this is obvious, since $\varphi_p = \operatorname{id}$. Thus, the family $(b_n)_{n\geq 1} = (q)_{n\geq 1}$ satisfies Assertion $\mathcal{C}$.
- *Proof of Assertion $\mathcal{C}$ for the family $(b_n)_{n\geq 1} = \left(\dbinom{qn}{rn}\right)_{n\geq 1}$, where $r \in \mathbb{Q}$ and $q \in \mathbb{Z}$ are given:* Let $r \in \mathbb{Q}$ and $q \in \mathbb{Z}$. We need to prove Assertion $\mathcal{C}$ for the family $(b_n)_{n\geq 1} = \left(\dbinom{qn}{rn}\right)_{n\geq 1}$. This means proving that for every positive integer n and every prime factor p of n, we have
$$\varphi_p\left(\binom{qn/p}{rn/p}\right) \equiv \binom{qn}{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z}. \tag{13.85.2}$$
So let us prove this. Let n be a positive integer, and p be a prime factor of n. We need to prove (13.85.2). In other words, we need to prove that
$$\binom{qn/p}{rn/p} \equiv \binom{qn}{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z} \tag{13.85.3}$$
(since $\varphi_p = \operatorname{id}$). We WLOG assume that $rn \in \mathbb{Z}$ (since otherwise, both sides of this congruence (13.85.3) are 0).

It is well-known that $(1+X)^p \equiv 1 + X^p \operatorname{mod} p\mathbb{Z}[X]$ in the polynomial ring $\mathbb{Z}[X]$. Hence, $((1+X)^p)^{n/p} \equiv (1+X^p)^{n/p} \operatorname{mod} p^{v_p(n/p)+1}\mathbb{Z}[X]$ (by (13.84.8), applied to $\mathbb{Z}[X]$, $(1+X)^p$, $1+X^p$ and n/p instead of A, a, b and N). Since $((1+X)^p)^{n/p} = (1+X)^n$ and $v_p(n/p) + 1 = v_p(n)$, this rewrites as
$$(1+X)^n \equiv (1+X^p)^{n/p} \operatorname{mod} p^{v_p(n)}\mathbb{Z}[X].$$
Hence,
$$(1+X)^n \equiv (1+X^p)^{n/p} \operatorname{mod} p^{v_p(n)}\mathbb{Z}[[X]]$$
(since $\mathbb{Z}[X]$ is a subring of $\mathbb{Z}[[X]]$). We can take both sides of this congruence to the q-th power[669], and thus obtain
$$((1+X)^n)^q \equiv \left((1+X^p)^{n/p}\right)^q \operatorname{mod} p^{v_p(n)}\mathbb{Z}[[X]].$$
In other words,
$$(1+X)^{qn} \equiv (1+X^p)^{qn/p} \operatorname{mod} p^{v_p(n)}\mathbb{Z}[[X]].$$
Comparing the coefficients before X^{rn} on both sides of this congruence, we obtain
$$\binom{qn}{rn} \equiv \binom{qn/p}{rn/p} \operatorname{mod} p^{v_p(n)}\mathbb{Z}.$$
This proves (13.85.3) and thus (13.85.2). Hence, we are done with the family $(b_n)_{n\geq 1} = \left(\dbinom{qn}{rn}\right)_{n\geq 1}$.

[*Remark:* There is an alternative, combinatorial approach to proving (13.85.3) when q is nonnegative. This approach proceeds by counting the (rn)-element subsets of the set $\mathbb{Z}/(qn)$. On the one

[669] This works even if q is negative, since $(1+X)^n$ and $(1+X^p)^{n/p}$ are invertible in $\mathbb{Z}[[X]] / \left(p^{v_p(n)}\mathbb{Z}[[X]]\right)$.

hand, the number of such subsets is clearly $\dbinom{qn}{rn}$. On the other hand, these subsets fall into two classes:

- the subsets which are invariant under the permutation
$$\mathbb{Z}/\left(qn\right) \to \mathbb{Z}/\left(qn\right), \qquad i \mapsto i + qn/p$$
of $\mathbb{Z}/\left(qn\right)$;
- the subsets which are not invariant under this permutation.

It is easy to see that the number of all subsets in the first class is $\dbinom{qn/p}{rn/p}$ (indeed, the intersection of such a subset with $\{0, 1, \ldots, qn/p - 1\} \subset \mathbb{Z}/\left(qn\right)$ must have rn/p elements, and uniquely determines the whole subset by "replication"), whereas the number of all subsets in the second class is divisible by $p^{v_p(n)}$ (because the permutation $\mathbb{Z}/\left(qn\right) \to \mathbb{Z}/\left(qn\right),\ i \mapsto i+1$ acts on these subsets, and thus splits them into orbits, each of which has size divisible by $p^{v_p(n)}$ [670]). Hence, the number of all subsets in both classes together is $\equiv \dbinom{qn/p}{rn/p} \operatorname{mod} p^{v_p(n)}\mathbb{Z}$. Comparing these two answers, we obtain $\dbinom{qn}{rn} \equiv \dbinom{qn/p}{rn/p} \operatorname{mod} p^{v_p(n)}\mathbb{Z}$.

The downside of this nice approach is that it requires a modification in the case when q is negative. Here, the *upper negation formula* $\dbinom{-a}{k} = (-1)^k \dbinom{a+k-1}{k}$ needs to be used, along with the "stars-and-bars" formula $\dbinom{a+k-1}{k}$ for the number of k-element multisets whose elements belong to $\{1, 2, \ldots, a\}$. We leave the details to the reader.]

- *Proof of Assertion $\mathcal{C}$ for the family $\left(b_n\right)_{n\geq 1} = \left(\dbinom{qn-1}{rn-1}\right)_{n\geq 1}$, where $r \in \mathbb{Z}$ and $q \in \mathbb{Z}$ are given:*

Let $r \in \mathbb{Z}$ and $q \in \mathbb{Z}$. We need to prove Assertion $\mathcal{C}$ for the family $\left(b_n\right)_{n\geq 1} = \left(\dbinom{qn-1}{rn-1}\right)_{n\geq 1}$. This means proving that for every positive integer n and every prime factor p of n, we have

$$\varphi_p \left(\dbinom{qn/p-1}{rn/p-1}\right) \equiv \dbinom{qn-1}{rn-1} \operatorname{mod} p^{v_p(n)}\mathbb{Z}. \tag{13.85.4}$$

[670] Here is why: Let O be an orbit under the action of the permutation $\mathbb{Z}/\left(qn\right) \to \mathbb{Z}/\left(qn\right),\ i \mapsto i+1$ on the subsets in the second class. We must prove that O has size divisible by $p^{v_p(n)}$.

Note that $qn \neq 0$, since otherwise there would be no subsets in the second class.

Let ξ be the permutation
$$\mathbb{Z}/\left(qn\right) \to \mathbb{Z}/\left(qn\right), \qquad i \mapsto i+1$$
of $\mathbb{Z}/\left(qn\right)$. Then, O is an orbit under the action of ξ on the subsets in the second class. Note that $\xi^{qn} = \operatorname{id}$, since ξ is a cyclic permutation of a qn-element set.

Fix an element $L \in O$. Thus, L is a subset in the second class. In other words, L is a subset of $\mathbb{Z}/\left(qn\right)$ that is not invariant under the permutation
$$\mathbb{Z}/\left(qn\right) \to \mathbb{Z}/\left(qn\right), \qquad i \mapsto i + qn/p$$
of $\mathbb{Z}/\left(qn\right)$. Since this permutation is $\xi^{qn/p}$, we can restate this as follows: L is a subset of $\mathbb{Z}/\left(qn\right)$ that is not invariant under the action of the permutation $\xi^{qn/p}$ on the subsets of $\mathbb{Z}/\left(qn\right)$. That is, $\xi^{qn/p}\left(L\right) \neq L$. But $\xi^{qn}\left(L\right) = L$ (since $\xi^{qn} = \operatorname{id}$). Now, O is the orbit of L under the action of ξ. Hence, the size of this orbit O is a divisor of qn (since $\xi^{qn}\left(L\right) = L$) but not a divisor of qn/p (since $\xi^{qn/p}\left(L\right) \neq L$). Thus, this size must be divisible by $p^{v_p(qn)}$ (because a divisor of qn that is not divisor of qn/p must necessarily be divisible by $p^{v_p(qn)}$). Hence, it is also divisible by $p^{v_p(n)}$ (since $v_p\left(qn\right) = \underbrace{v_p\left(q\right)}_{\geq 0} + v_p\left(n\right) \geq v_p\left(n\right)$ and therefore $p^{v_p(n)} \mid p^{v_p(qn)}$). Qed.

So let us prove this. Let n be a positive integer, and p be a prime factor of n. We need to prove (13.85.4). In other words, we need to prove that

$$\binom{qn/p-1}{rn/p-1} \equiv \binom{qn-1}{rn-1} \operatorname{mod} p^{v_p(n)}\mathbb{Z} \tag{13.85.5}$$

(since $\varphi_p = \mathrm{id}$). By the recurrence of the binomial coefficients, we have $\binom{qn/p-1}{rn/p-1} = \binom{qn/p}{rn/p} - \binom{qn/p-1}{rn/p}$ and $\binom{qn-1}{rn-1} = \binom{qn}{rn} - \binom{qn-1}{rn}$. Hence, we can obtain the desired congruence (13.85.5) by subtracting the congruence

$$\binom{qn/p-1}{rn/p} \equiv \binom{qn-1}{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z} \tag{13.85.6}$$

from the congruence (13.85.3). It therefore remains to prove the congruence (13.85.6) (since (13.85.3) has already been proven).

We recall the (easy-to-check) formula $\binom{a-1}{k} = (-1)^k \binom{k-a}{k}$ for every $a \in \mathbb{Z}$ and $k \in \mathbb{N}$. This formula allows us to rewrite both sides of (13.85.6), and thus (13.85.6) becomes

$$(-1)^{rn/p} \binom{rn/p - qn/p}{rn/p} \equiv (-1)^{rn} \binom{rn-qn}{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z}. \tag{13.85.7}$$

So it remains to prove (13.85.7). We have $(-1)^{rn/p} \equiv (-1)^{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z}$ [671]. Thus, we can cancel the $(-1)^{rn/p}$ on the left hand side of (13.85.7) against the $(-1)^{rn}$ on the right hand side, and therefore (13.85.7) takes the equivalent form

$$\binom{rn/p - qn/p}{rn/p} \equiv \binom{rn-qn}{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z}.$$

This further rewrites as

$$\binom{(r-q)\,n/p}{rn/p} \equiv \binom{(r-q)\,n}{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z}.$$

But this follows from (13.85.3), applied to $r-q$ instead of q. Hence, (13.85.7) is proven, and consequently Assertion $\mathcal{C}$ holds for the family $(b_n)_{n\geq 1} = \left(\binom{qn-1}{rn-1}\right)_{n\geq 1}$.

Exercise 2.9.8 is thus solved.

13.86. **Solution to Exercise 2.9.9.** *Solution to Exercise 2.9.9.* (a) This is obvious since $\mathbf{f}_n$ is an evaluation homomorphism (in an appropriate sense).[672]

(b) Let n and m be positive integers. Then,

$$\begin{aligned}(\mathbf{f}_n \circ \mathbf{f}_m)(a) &= \mathbf{f}_n \left(\underbrace{\mathbf{f}_m(a)}_{=a\left(x_1^m, x_2^m, x_3^m, \ldots\right)} \right) = \mathbf{f}_n \left(a\left(x_1^m, x_2^m, x_3^m, \ldots\right)\right) = \left(a\left(x_1^m, x_2^m, x_3^m, \ldots\right)\right)\left(x_1^n, x_2^n, x_3^n, \ldots\right) \\ &= a\left(\left(x_1^n\right)^m, \left(x_2^n\right)^m, \left(x_3^n\right)^m, \ldots\right) = a\left(x_1^{nm}, x_2^{nm}, x_3^{nm}, \ldots\right) = \mathbf{f}_{nm}(a)\end{aligned}$$

for all $a \in \Lambda$. Thus, $\mathbf{f}_n \circ \mathbf{f}_m = \mathbf{f}_{nm}$, so that Exercise 2.9.9(b) is solved.

[671] *Proof.* The only situation in which this is not obvious is when one of the integers rn/p and rn is even and the other is odd. This means, of course, that rn/p is odd and rn is even (since $rn/p \mid rn$). Hence, in this situation, we have $p = 2$ and $v_p(n) \leq 1$, and therefore $p^{v_p(n)} = 2$, so that $(-1)^{rn/p} \equiv (-1)^{rn} \operatorname{mod} p^{v_p(n)}\mathbb{Z}$ follows immediately from the fact that any two integer powers of -1 are congruent to each other modulo $2\mathbb{Z}$.

[672] Or, in a more down-to-earth fashion, this is obvious because (for example) multiplying two power series and then replacing all variables in the product by their n-th powers gives the same result as first replacing all variables by their n-th powers and then multiplying the resulting two power series.

(c) For every $a \in \Lambda$, we have $\mathbf{f}_1(a) = a\left(x_1^1, x_2^1, x_3^1, \ldots\right) = a$. Thus, $\mathbf{f}_1 = \operatorname{id}$, so that Exercise 2.9.9(c) is solved.

(d) There are several ways to solve Exercise 2.9.9(d):

- One can check $\Delta \circ \mathbf{f}_n = (\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta$ rather directly on the basis $(m_\lambda)_{\lambda \in \operatorname{Par}}$ of Λ, using (2.1.4) and the definition of $\mathbf{f}_n$.
- One can check $\Delta \circ \mathbf{f}_n = (\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta$ very easily on the elements $p_1, p_2, p_3, \ldots$ of Λ, and then "pretend" that these elements generate Λ (in fact, they do generate Λ when $\mathbf{k} = \mathbb{Q}$, so this solves Exercise 2.9.9(d) in the case of $\mathbf{k} = \mathbb{Q}$; but this easily entails that Exercise 2.9.9(d) holds in the case of $\mathbf{k} = \mathbb{Z}$ [673], and this, in turn, can be used to solve Exercise 2.9.9(d) for arbitrary $\mathbf{k}$ [674]).
- One can derive Exercise 2.9.9(d) from Exercise 2.9.10(e) using the self-duality of Λ and Exercise 2.9.10(f). This is somewhat complicated by the fact that $\mathbf{v}_n$ and $\mathbf{f}_n$ (generally) are not graded maps[675], but with the correct arguments, one can completely avoid any use of gradedness[676].

Probably the following solution of Exercise 2.9.9(d) is the shortest:

[673] Getting from $\mathbf{k} = \mathbb{Q}$ to $\mathbf{k} = \mathbb{Z}$ requires a standard functoriality argument. See Step 2 of the solution of Exercise 2.9.10(g) further below for an example of such an argument.

[674] Getting from $\mathbf{k} = \mathbb{Z}$ to arbitrary $\mathbf{k}$ requires a standard functoriality argument. See Step 3 of the solution of Exercise 2.9.10(g) further below for an example of such an argument.

[675] They nevertheless have a property close to being graded. Namely, let us say that a $\mathbf{k}$-linear map φ between two graded $\mathbf{k}$-modules $V = \bigoplus_{n \geq 0} V_n$ and $W = \bigoplus_{n \geq 0} W_n$ *scales the degree by* q (where q is some fixed rational number) if it has the property that $\varphi(V_n) \subset W_{qn}$ for all $n \in \mathbb{N}$ (where W_{qn} is understood to be 0 when qn is not an integer). Then, $\mathbf{v}_n$ scales the degree by $1/n$, whereas $\mathbf{f}_n$ scales the degree by n. When a $\mathbf{k}$-linear map φ between two graded $\mathbf{k}$-modules V and W scales the degree by a nonzero rational number q, the adjoint map $\varphi^* : W^* \to V^*$ restricts to a $\mathbf{k}$-linear map $W^o \to V^o$, which scales the degree by $1/q$; thus a large part of the theory of adjoint maps which is usually formulated for graded maps can be carried over to the case of maps scaling the degree by q.

[676] Here is a sketch of how these correct arguments look like.

The Hall inner product $(\cdot, \cdot)_\Lambda$ on Λ gives rise to a symmetric bilinear form $(\cdot, \cdot)_{\Lambda \otimes \Lambda}$ on $\Lambda \otimes \Lambda$ (according to Definition 3.1.2(b)). It is easy to see that every three elements a, b and c of Λ satisfy

$$(a, m(b \otimes c))_\Lambda = (\Delta(a), b \otimes c)_{\Lambda \otimes \Lambda}. \tag{13.86.1}$$

[*Proof of* (13.86.1)*:* Let a, b and c be three elements of Λ. We need to prove the equality (13.86.1). Since this equality is $\mathbf{k}$-linear in each of a, b and c, we can WLOG assume that each of a, b and c belongs to the basis $(s_\lambda)_{\lambda \in \operatorname{Par}}$ of the $\mathbf{k}$-module Λ. Assume this. Then, there exist three elements α, β and γ of Par such that $a = s_\alpha$, $b = s_\beta$ and $c = s_\gamma$. Consider these α, β and γ. Now, let us use the notations of Corollary 2.5.7. Applying Corollary 2.5.7 to $\lambda = \alpha$, $\mu = \beta$ and $\nu = \gamma$ yields $c^\alpha_{\beta,\gamma} = \hat{c}^\alpha_{\beta,\gamma}$. But the definition of the map m yields

$$m(b \otimes c) = \underbrace{b}_{=s_\beta}\underbrace{c}_{=s_\gamma} = s_\beta s_\gamma = \sum_{\lambda \in \operatorname{Par}} c^\lambda_{\beta,\gamma} s_\lambda$$

(by (2.5.6), applied to $\mu = \beta$ and $\nu = \gamma$). Hence,

$$\left(\underbrace{a}_{=s_\alpha}, \underbrace{m(b \otimes c)}_{=\sum_{\lambda \in \operatorname{Par}} c^\lambda_{\beta,\gamma} s_\lambda}\right)_\Lambda = \left(s_\alpha, \sum_{\lambda \in \operatorname{Par}} c^\lambda_{\beta,\gamma} s_\lambda\right)_\Lambda = \sum_{\lambda \in \operatorname{Par}} c^\lambda_{\beta,\gamma} \underbrace{(s_\alpha, s_\lambda)_\Lambda}_{=\delta_{\alpha,\lambda}} = \sum_{\lambda \in \operatorname{Par}} c^\lambda_{\beta,\gamma} \delta_{\alpha,\lambda} = c^\alpha_{\beta,\gamma} = \hat{c}^\alpha_{\beta,\gamma}.$$

On the other hand, applying the map Δ to both sides of the equality $a = s_\alpha$, we obtain

$$\Delta a = \Delta s_\alpha = \sum_{\mu \in \operatorname{Par};\ \nu \in \operatorname{Par}} \hat{c}^\alpha_{\mu,\nu} s_\mu \otimes s_\nu$$

(by (2.5.7), applied to $\lambda = \alpha$). Hence,

$$\begin{aligned}
\left(\underbrace{\Delta a}_{=\sum_{\mu \in \operatorname{Par};\ \nu \in \operatorname{Par}} \hat{c}^\alpha_{\mu,\nu} s_\mu \otimes s_\nu}, \underbrace{b}_{=s_\beta} \otimes \underbrace{c}_{=s_\gamma}\right)_{\Lambda \otimes \Lambda} &= \left(\sum_{\mu \in \operatorname{Par};\ \nu \in \operatorname{Par}} \hat{c}^\alpha_{\mu,\nu} s_\mu \otimes s_\nu, s_\beta \otimes s_\gamma\right)_{\Lambda \otimes \Lambda} \\
&= \sum_{\mu \in \operatorname{Par};\ \nu \in \operatorname{Par}} \hat{c}^\alpha_{\mu,\nu} \underbrace{(s_\mu \otimes s_\nu, s_\beta \otimes s_\gamma)_{\Lambda \otimes \Lambda}}_{=(s_\mu, s_\beta)_\Lambda (s_\nu, s_\gamma)_\Lambda} = \sum_{\mu \in \operatorname{Par};\ \nu \in \operatorname{Par}} \hat{c}^\alpha_{\mu,\nu} \underbrace{(s_\mu, s_\beta)_\Lambda}_{=\delta_{\mu,\beta}} \underbrace{(s_\nu, s_\gamma)_\Lambda}_{=\delta_{\nu,\gamma}} \\
&= \sum_{\mu \in \operatorname{Par};\ \nu \in \operatorname{Par}} \hat{c}^\alpha_{\mu,\nu} \delta_{\mu,\beta} \delta_{\nu,\gamma} = \sum_{\mu \in \operatorname{Par}} \delta_{\mu,\beta} \underbrace{\sum_{\nu \in \operatorname{Par}} \hat{c}^\alpha_{\mu,\nu} \delta_{\nu,\gamma}}_{=\hat{c}^\alpha_{\mu,\gamma}} = \sum_{\mu \in \operatorname{Par}} \delta_{\mu,\beta} \hat{c}^\alpha_{\mu,\gamma} = \hat{c}^\alpha_{\beta,\gamma}.
\end{aligned}$$

Compared with $(a, m(b \otimes c))_\Lambda = \hat{c}^\alpha_{\beta,\gamma}$, this yields $(a, m(b \otimes c))_\Lambda = (\Delta(a), b \otimes c)_{\Lambda \otimes \Lambda}$. Thus, (13.86.1) is proven.]

Fix $n \in \{1, 2, 3, \ldots\}$. We need to prove that $\mathbf{f}_n : \Lambda \to \Lambda$ is a Hopf algebra homomorphism. We already know that $\mathbf{f}_n$ is a $\mathbf{k}$-algebra homomorphism. Therefore, if we can show that $\mathbf{f}_n$ is a $\mathbf{k}$-coalgebra homomorphism, then it will immediately follow that $\mathbf{f}_n$ is a $\mathbf{k}$-bialgebra homomorphism and thus a Hopf algebra homomorphism (due to Corollary 1.4.27). Therefore, it remains to show that $\mathbf{f}_n$ is a $\mathbf{k}$-coalgebra homomorphism. To do so, we need to check that $\epsilon \circ \mathbf{f}_n = \epsilon$ and $\Delta \circ \mathbf{f}_n = (\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta$. We shall only prove $\Delta \circ \mathbf{f}_n = (\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta$, while the easy proof of $\epsilon \circ \mathbf{f}_n = \epsilon$ is left to the reader.

Let us first notice that Λ is a bialgebra, and therefore Δ is a $\mathbf{k}$-algebra homomorphism (by the axioms of a bialgebra). Also, $\mathbf{f}_n$ is a $\mathbf{k}$-algebra homomorphism. Thus, $\Delta \circ \mathbf{f}_n$ and $(\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta$ are $\mathbf{k}$-algebra homomorphisms.

For every $m \in \mathbb{N}$, let us define an element $\widetilde{h}_m \in \mathbf{k}[[\mathbf{x}]]$ by $\widetilde{h}_m = \sum_{i_1 \leq i_2 \leq \cdots \leq i_m} x_{i_1}^n x_{i_2}^n \cdots x_{i_m}^n$. Then, it is easy to see that

$$\mathbf{f}_n(h_m) = \widetilde{h}_m \qquad \text{for every } m \in \mathbb{N}. \tag{13.86.6}$$

Now, we can show that every $a \in \Lambda$ and $B \in \Lambda \otimes \Lambda$ satisfy

$$(a, m(B))_\Lambda = (\Delta(a), B)_{\Lambda \otimes \Lambda}. \tag{13.86.2}$$

[*Proof of* (13.86.2)*:* Let $a \in \Lambda$ and $B \in \Lambda \otimes \Lambda$. We need to prove the equality (13.86.2). Since this equality is $\mathbf{k}$-linear in B, we can WLOG assume that B is a pure tensor (because the pure tensors span the $\mathbf{k}$-module $\Lambda \otimes \Lambda$). Assume this. Then, $B = b \otimes c$ for two elements b and c of Λ. Consider these b and c. Then,

$$\begin{aligned}\left(a, m\left(\underbrace{B}_{=b\otimes c}\right)\right)_\Lambda &= (a, m(b \otimes c))_\Lambda = \left(\Delta(a), \underbrace{b \otimes c}_{=B}\right)_{\Lambda \otimes \Lambda} \qquad (\text{by } (13.86.1)) \\ &= (\Delta(a), B)_{\Lambda \otimes \Lambda}.\end{aligned}$$

This proves (13.86.2).]

Exercise 2.9.10(f) yields that the maps $\mathbf{f}_n : \Lambda \to \Lambda$ and $\mathbf{v}_n : \Lambda \to \Lambda$ are adjoint with respect to the Hall inner product on Λ. Thus,

$$(\mathbf{f}_n a, b)_\Lambda = (a, \mathbf{v}_n b)_\Lambda \qquad \text{for every } a \in \Lambda \text{ and } b \in \Lambda. \tag{13.86.3}$$

From this, it is easy to see that

$$((\mathbf{f}_n \otimes \mathbf{f}_n) A, B)_{\Lambda \otimes \Lambda} = (A, (\mathbf{v}_n \otimes \mathbf{v}_n) B)_{\Lambda \otimes \Lambda} \qquad \text{for every } A \in \Lambda \otimes \Lambda \text{ and } B \in \Lambda \otimes \Lambda. \tag{13.86.4}$$

[*Proof of (13.86.4):* Let $A \in \Lambda \otimes \Lambda$ and $B \in \Lambda \otimes \Lambda$. We have to prove the equality (13.86.4). Since this equality is $\mathbf{k}$-linear in each of A and B, we can WLOG assume that A and B are pure tensors (since pure tensors span $\Lambda \otimes \Lambda$ as a $\mathbf{k}$-module). Assume this. Then, we can write A and B in the forms $A = a_1 \otimes a_2$ and $B = b_1 \otimes b_2$ for some $a_1, a_2 \in \Lambda$ and $b_1, b_2 \in \Lambda$. Consider these a_1, a_2 and b_1, b_2. Now,

$$\begin{aligned}\left((\mathbf{f}_n \otimes \mathbf{f}_n) \underbrace{A}_{=a_1 \otimes a_2}, \underbrace{B}_{=b_1 \otimes b_2}\right)_{\Lambda \otimes \Lambda} &= \left(\underbrace{(\mathbf{f}_n \otimes \mathbf{f}_n)(a_1 \otimes a_2)}_{=(\mathbf{f}_n a_1) \otimes (\mathbf{f}_n a_2)}, b_1 \otimes b_2\right)_{\Lambda \otimes \Lambda} = ((\mathbf{f}_n a_1) \otimes (\mathbf{f}_n a_2), b_1 \otimes b_2)_{\Lambda \otimes \Lambda} \\ &= \underbrace{(\mathbf{f}_n a_1, b_1)_\Lambda}_{\substack{=(a_1, \mathbf{v}_n b_1)_\Lambda \\ (\text{by } (13.86.3), \text{ applied to} \\ a=a_1 \text{ and } b=b_1)}} \underbrace{(\mathbf{f}_n a_2, b_2)_\Lambda}_{\substack{=(a_2, \mathbf{v}_n b_2)_\Lambda \\ (\text{by } (13.86.3), \text{ applied to} \\ a=a_2 \text{ and } b=b_2)}} \\ &= (a_1, \mathbf{v}_n b_1)_\Lambda (a_2, \mathbf{v}_n b_2)_\Lambda.\end{aligned}$$

Compared with

$$\begin{aligned}\left(\underbrace{A}_{=a_1 \otimes a_2}, (\mathbf{v}_n \otimes \mathbf{v}_n) \underbrace{B}_{=b_1 \otimes b_2}\right)_{\Lambda \otimes \Lambda} &= \left(a_1 \otimes a_2, \underbrace{(\mathbf{v}_n \otimes \mathbf{v}_n)(b_1 \otimes b_2)}_{=\mathbf{v}_n(b_1) \otimes \mathbf{v}_n(b_2)}\right)_{\Lambda \otimes \Lambda} \\ &= (a_1 \otimes a_2, \mathbf{v}_n(b_1) \otimes \mathbf{v}_n(b_2))_{\Lambda \otimes \Lambda} = (a_1, \mathbf{v}_n b_1)_\Lambda (a_2, \mathbf{v}_n b_2)_\Lambda,\end{aligned}$$

this yields $((\mathbf{f}_n \otimes \mathbf{f}_n) A, B)_{\Lambda \otimes \Lambda} = (A, (\mathbf{v}_n \otimes \mathbf{v}_n) B)_{\Lambda \otimes \Lambda}$. This proves (13.86.4).]

Let us now show that $(\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta = \Delta \circ \mathbf{f}_n$ (this is one of the axioms that need to be checked in order to show that $\mathbf{f}_n$ is a Hopf algebra homomorphism).

Indeed, $\mathbf{v}_n$ is a $\mathbf{k}$-algebra homomorphism. Hence, $m \circ (\mathbf{v}_n \otimes \mathbf{v}_n) = \mathbf{v}_n \circ m$.

[677] As a consequence, $\widetilde{h}_m = \mathbf{f}_n(h_m) \in \Lambda$ for every $m \in \mathbb{N}$. (Of course, this was obvious anyway.)

Fix a positive integer r. Proposition 2.3.6(iii) (applied to r instead of n) states that $\Delta h_r = \sum_{i+j=r} h_i \otimes h_j$. The proof of this proposition (which proceeded by observing that $h_r(\mathbf{x}, \mathbf{y}) = \sum_{i+j=r} h_i(\mathbf{x}) h_j(\mathbf{y})$ in $\mathbf{k}[[\mathbf{x}, \mathbf{y}]]$) can be easily modified to obtain a proof of the equality $\Delta \widetilde{h}_r = \sum_{i+j=r} \widetilde{h}_i \otimes \widetilde{h}_j$. Thus, we have

$$\Delta \widetilde{h}_r = \sum_{i+j=r} \widetilde{h}_i \otimes \widetilde{h}_j . \tag{13.86.7}$$

Now,

$$(\Delta \circ \mathbf{f}_n)(h_r) = \Delta \left(\underbrace{\mathbf{f}_n(h_r)}_{\substack{= \widetilde{h}_r \\ \text{(by (13.86.6), applied to } m=r)}} \right) = \Delta \widetilde{h}_r = \sum_{i+j=r} \widetilde{h}_i \otimes \widetilde{h}_j \qquad \text{(by (13.86.7))} .$$

Now, let $a \in \Lambda$. Every $B \in \Lambda \otimes \Lambda$ satisfies

$$\begin{aligned}
\Big(\underbrace{((\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta)(a)}_{= (\mathbf{f}_n \otimes \mathbf{f}_n)(\Delta a)}, B \Big)_{\Lambda \otimes \Lambda} &= ((\mathbf{f}_n \otimes \mathbf{f}_n)(\Delta a), B)_{\Lambda \otimes \Lambda} = (\Delta a, (\mathbf{v}_n \otimes \mathbf{v}_n) B)_{\Lambda \otimes \Lambda} \\
&\qquad \text{(by (13.86.4), applied to } A = \Delta a) \\
&= (\Delta a, (\mathbf{v}_n \otimes \mathbf{v}_n) B)_{\Lambda \otimes \Lambda} = \Big(a, \underbrace{m((\mathbf{v}_n \otimes \mathbf{v}_n) B)}_{= (m \circ (\mathbf{v}_n \otimes \mathbf{v}_n))(B)} \Big)_{\Lambda} \\
&\qquad \left(\begin{array}{c} \text{because } (a, m((\mathbf{v}_n \otimes \mathbf{v}_n) B))_{\Lambda} = (\Delta a, (\mathbf{v}_n \otimes \mathbf{v}_n) B)_{\Lambda \otimes \Lambda} \\ \text{(by (13.86.2), applied to } (\mathbf{v}_n \otimes \mathbf{v}_n) B \text{ instead of } B) \end{array} \right) \\
&= \Big(a, \underbrace{(m \circ (\mathbf{v}_n \otimes \mathbf{v}_n))}_{= \mathbf{v}_n \circ m}(B) \Big)_{\Lambda} = \Big(a, \underbrace{(\mathbf{v}_n \circ m)(B)}_{= \mathbf{v}_n(mB)} \Big)_{\Lambda} = (a, \mathbf{v}_n(mB))_{\Lambda} = (\mathbf{f}_n a, mB)_{\Lambda} \\
&\qquad \left(\begin{array}{c} \text{because } (\mathbf{f}_n a, mB)_{\Lambda} = (a, \mathbf{v}_n(mB))_{\Lambda} \\ \text{(by (13.86.3), applied to } mB \text{ instead of } b) \end{array} \right) \\
&= \Big(\underbrace{\Delta(\mathbf{f}_n a)}_{= (\Delta \circ \mathbf{f}_n)(a)}, B \Big)_{\Lambda \otimes \Lambda} \qquad \text{(by (13.86.2), applied to } \mathbf{f}_n a \text{ instead of } a) \\
&= ((\Delta \circ \mathbf{f}_n)(a), B)_{\Lambda \otimes \Lambda} .
\end{aligned} \tag{13.86.5}$$

Now, the bilinear form $(\cdot, \cdot)_{\Lambda \otimes \Lambda}$ is nondegenerate (in fact, $(s_\mu \otimes s_\nu)_{(\mu,\nu) \in \operatorname{Par} \times \operatorname{Par}}$ is an orthonormal basis with respect to this bilinear form). Hence, if U and V are two elements of $\Lambda \otimes \Lambda$ such that every $B \in \Lambda \otimes \Lambda$ satisfies $(U, B)_{\Lambda \otimes \Lambda} = (V, B)_{\Lambda \otimes \Lambda}$, then $U = V$. Applying this to $U = ((\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta) a$ and $V = (\Delta \circ \mathbf{f}_n) a$, we obtain $((\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta) a = (\Delta \circ \mathbf{f}_n) a$ (because of (13.86.5)). Since we have proven this for every $a \in \Lambda$, this yields that $(\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta = \Delta \circ \mathbf{f}_n$. Thus, $(\mathbf{f}_n \otimes \mathbf{f}_n) \circ \Delta = \Delta \circ \mathbf{f}_n$ is proven.

[677] *Proof of (13.86.6):* Let $m \in \mathbb{N}$. Then, (2.2.3) (applied to m instead of n) yields $h_m = \sum_{i_1 \leq i_2 \leq \cdots \leq i_m} x_{i_1} x_{i_2} \cdots x_{i_m}$. Thus,

$$h_m(x_1^n, x_2^n, x_3^n, \ldots) = \left(\sum_{i_1 \leq i_2 \leq \cdots \leq i_m} x_{i_1} x_{i_2} \cdots x_{i_m} \right) (x_1^n, x_2^n, x_3^n, \ldots) = \sum_{i_1 \leq i_2 \leq \cdots \leq i_m} x_{i_1}^n x_{i_2}^n \cdots x_{i_m}^n .$$

But the definition of $\mathbf{f}_n$ yields $\mathbf{f}_n(h_m) = h_m(x_1^n, x_2^n, x_3^n, \ldots) = \sum_{i_1 \leq i_2 \leq \cdots \leq i_m} x_{i_1}^n x_{i_2}^n \cdots x_{i_m}^n$. This proves (13.86.6).

Compared with

$$\begin{aligned}\left(\left(\mathbf{f}_n\otimes\mathbf{f}_n\right)\circ\Delta\right)\left(h_r\right)&=\left(\mathbf{f}_n\otimes\mathbf{f}_n\right)\left(\underbrace{\Delta h_r}_{=\sum_{i+j=r}h_i\otimes h_j}\right)=\left(\mathbf{f}_n\otimes\mathbf{f}_n\right)\left(\sum_{i+j=r}h_i\otimes h_j\right)\\&=\sum_{i+j=r}\underbrace{\mathbf{f}_n\left(h_i\right)}_{\substack{=\widetilde{h}_i\\ \text{(by (13.86.6), applied to } m=i)}}\otimes\underbrace{\mathbf{f}_n\left(h_j\right)}_{\substack{=\widetilde{h}_j\\ \text{(by (13.86.6), applied to } m=j)}}=\sum_{i+j=r}\widetilde{h}_i\otimes\widetilde{h}_j,\end{aligned}$$

this yields $\left(\Delta\circ\mathbf{f}_n\right)\left(h_r\right)=\left(\left(\mathbf{f}_n\otimes\mathbf{f}_n\right)\circ\Delta\right)\left(h_r\right)$.

Now, let us forget that we fixed r. We thus have proven that

$$(13.86.8)\qquad \left(\Delta\circ\mathbf{f}_n\right)\left(h_r\right)=\left(\left(\mathbf{f}_n\otimes\mathbf{f}_n\right)\circ\Delta\right)\left(h_r\right)\qquad\text{for every positive integer } r.$$

Now, recall that the family $\left(h_r\right)_{r\geq 1}$ generates the $\mathbf{k}$-algebra Λ (according to Proposition 2.4.1). In other words, $\left(h_r\right)_{r\geq 1}$ is a generating set of the $\mathbf{k}$-algebra Λ. The two $\mathbf{k}$-algebra homomorphisms $\Delta\circ\mathbf{f}_n$ and $\left(\mathbf{f}_n\otimes\mathbf{f}_n\right)\circ\Delta$ are equal to each other on this generating set (according to (13.86.8)), and therefore must be identical (because if two $\mathbf{k}$-algebra homomorphisms from the same domain are equal to each other on a generating set of their domain, then these two homomorphisms must be identical). In other words, $\Delta\circ\mathbf{f}_n=\left(\mathbf{f}_n\otimes\mathbf{f}_n\right)\circ\Delta$. This completes the solution of Exercise 2.9.9(d).

(e) Let $m\in\mathbb{N}$. From (2.2.18), we have $\prod_{i=1}^{\infty}\left(1-x_it\right)^{-1}=\sum_{n\geq 0}h_n\left(\mathbf{x}\right)t^n$ in the ring $\Lambda\left[\left[t\right]\right]$. Substituting x_i^2 for x_i and t^2 for t in this equality, we obtain

$$(13.86.9)\qquad \prod_{i=1}^{\infty}\left(1-x_i^2t^2\right)^{-1}=\sum_{n\geq 0}h_n\left(x_1^2,x_2^2,x_3^2,\ldots\right)\left(t^2\right)^n.$$

But

$$(13.86.10)\qquad \prod_{i=1}^{\infty}\left(1-x_it\right)^{-1}=\sum_{n\geq 0}\underbrace{h_n\left(\mathbf{x}\right)}_{=h_n}t^n=\sum_{n\geq 0}h_nt^n.$$

Substituting $-t$ for t in this equality, we obtain $\prod_{i=1}^{\infty}\left(1-x_i\left(-t\right)\right)^{-1}=\sum_{n\geq 0}h_n\left(-t\right)^n=\sum_{n\geq 0}\left(-1\right)^nh_nt^n$. Thus,

$$(13.86.11)\qquad \sum_{n\geq 0}\left(-1\right)^nh_nt^n=\prod_{i=1}^{\infty}\left(\underbrace{1-x_i\left(-t\right)}_{=1+x_it}\right)^{-1}=\prod_{i=1}^{\infty}\left(1+x_it\right)^{-1}.$$

Now,

$$\begin{aligned}\sum_{n\geq 0}\underbrace{\mathbf{f}_2\left(h_n\right)}_{\substack{=h_n\left(x_1^2,x_2^2,x_3^2,\ldots\right)\\ \text{(by the definition of } \mathbf{f}_2)}}\underbrace{t^{2n}}_{=\left(t^2\right)^n}&=\sum_{n\geq 0}h_n\left(x_1^2,x_2^2,x_3^2,\ldots\right)\left(t^2\right)^n=\prod_{i=1}^{\infty}\left(\underbrace{1-x_i^2t^2}_{=\left(1-x_it\right)\left(1+x_it\right)}\right)^{-1}\qquad\text{(by (13.86.9))}\\&=\prod_{i=1}^{\infty}\left(\left(1-x_it\right)\left(1+x_it\right)\right)^{-1}=\underbrace{\left(\prod_{i=1}^{\infty}\left(1-x_it\right)^{-1}\right)}_{\substack{=\sum_{n\geq 0}h_nt^n\\ \text{(by (13.86.10))}}}\underbrace{\left(\prod_{i=1}^{\infty}\left(1+x_it\right)^{-1}\right)}_{\substack{=\sum_{n\geq 0}\left(-1\right)^nh_nt^n\\ \text{(by (13.86.11))}}}\\&=\left(\sum_{n\geq 0}h_nt^n\right)\left(\sum_{n\geq 0}\left(-1\right)^nh_nt^n\right)=\sum_{n\geq 0}\left(\sum_{i=0}^{n}h_i\cdot\left(-1\right)^{n-i}h_{n-i}\right)t^n\\&\qquad\text{(by the definition of the product of two formal power series)}.\end{aligned}$$

Comparing coefficients before t^{2m} on both sides of this equality, we obtain

$$\mathbf{f}_2\left(h_m\right) = \sum_{i=0}^{2m} h_i \cdot \underbrace{(-1)^{2m-i}}_{\substack{=(-1)^i \\ (\text{since } 2m-i \equiv i \bmod 2)}} h_{2m-i} = \sum_{i=0}^{2m} h_i \cdot (-1)^i h_{2m-i} = \sum_{i=0}^{2m} (-1)^i h_i h_{2m-i}.$$

Exercise 2.9.9(e) is thus solved.

(f) Let p be a prime number, and let $a \in \Lambda$. We need to prove that $\mathbf{f}_p\left(a\right) \equiv a^p \bmod p\Lambda$.

Indeed, let us first check that $\mathbf{f}_p\left(a\right) \equiv a^p \bmod p\mathbb{Z}\left[\left[\mathbf{x}\right]\right]$. Since $\mathbf{f}_p\left(a\right) = a\left(x_1^p, x_2^p, x_3^p, \ldots\right)$, this is equivalent to showing that $a\left(x_1^p, x_2^p, x_3^p, \ldots\right) \equiv a^p \bmod p\mathbb{Z}\left[\left[\mathbf{x}\right]\right]$. This, in turn, is equivalent to proving that $\overline{a}\left(x_1^p, x_2^p, x_3^p, \ldots\right) = \overline{a}^p$, where $\overline{a}$ denotes the projection of the power series $a \in \mathbb{Z}\left[\left[\mathbf{x}\right]\right]$ onto the ring $\left(\mathbb{Z}/p\mathbb{Z}\right)\left[\left[\mathbf{x}\right]\right]$ (by reducing every coefficient modulo p). So let us prove $\overline{a}\left(x_1^p, x_2^p, x_3^p, \ldots\right) = \overline{a}^p$ now.

Write the power series $\overline{a}$ in the form $\overline{a} = \sum_\beta \kappa_\beta \mathbf{x}^\beta$, where the sum ranges over all weak compositions β, and where κ_β is an element of $\mathbb{Z}/p\mathbb{Z}$ for every weak composition β. Taking both sides of this equality to the p-th power, we obtain

$$\overline{a}^p = \left(\sum_\beta \kappa_\beta \mathbf{x}^\beta\right)^p . \qquad (13.86.12)$$

In the commutative ring $\left(\mathbb{Z}/p\mathbb{Z}\right)\left[\left[\mathbf{x}\right]\right]$, we have $p \cdot 1_{\left(\mathbb{Z}/p\mathbb{Z}\right)\left[\left[\mathbf{x}\right]\right]} = 0$. Thus, taking the p-th power is a ring endomorphism of $\left(\mathbb{Z}/p\mathbb{Z}\right)\left[\left[\mathbf{x}\right]\right]$. This ring endomorphism is moreover continuous (with respect to the usual topology on $\left(\mathbb{Z}/p\mathbb{Z}\right)\left[\left[\mathbf{x}\right]\right]$) and $\left(\mathbb{Z}/p\mathbb{Z}\right)$-linear (by virtue of being a ring endomorphism). Thus, this endomorphism respects infinite $\left(\mathbb{Z}/p\mathbb{Z}\right)$-linear combinations; hence,

$$\left(\sum_\beta \kappa_\beta \mathbf{x}^\beta\right)^p = \sum_\beta \kappa_\beta \left(\mathbf{x}^\beta\right)^p . \qquad (13.86.13)$$

But $\overline{a} = \sum_\beta \kappa_\beta \mathbf{x}^\beta$, so that $\overline{a}\left(x_1^p, x_2^p, x_3^p, \ldots\right) = \sum_\beta \kappa_\beta \left(\mathbf{x}^\beta\right)^p$ (because replacing all variables $x_1, x_2, x_3, \ldots$ by their p-th powers transforms every monomial $\mathbf{x}^\beta$ into $\left(\mathbf{x}^\beta\right)^p$). Thus,

$$\begin{aligned} \overline{a}\left(x_1^p, x_2^p, x_3^p, \ldots\right) &= \sum_\beta \kappa_\beta \left(\mathbf{x}^\beta\right)^p = \left(\sum_\beta \kappa_\beta \mathbf{x}^\beta\right)^p \qquad (\text{by } (13.86.13)) \\ &= \overline{a}^p \qquad (\text{by } (13.86.12)) . \end{aligned}$$

We thus have proven that $\overline{a}\left(x_1^p, x_2^p, x_3^p, \ldots\right) = \overline{a}^p$. As explained above, this yields $\mathbf{f}_p\left(a\right) \equiv a^p \bmod p\mathbb{Z}\left[\left[\mathbf{x}\right]\right]$. In other words, the power series $\dfrac{\mathbf{f}_p\left(a\right) - a^p}{p}$ (this is, a priori, an element of $\mathbb{Q}\left[\left[\mathbf{x}\right]\right]$) belongs to $\mathbb{Z}\left[\left[\mathbf{x}\right]\right]$. Since this power series is also of bounded degree and symmetric (because so are $\mathbf{f}_p\left(a\right)$ and a^p), it follows that it lies in Λ. So we have $\dfrac{\mathbf{f}_p\left(a\right) - a^p}{p} \in \Lambda$, thus $\mathbf{f}_p\left(a\right) - a^p \in p\Lambda$ and hence $\mathbf{f}_p\left(a\right) \equiv a^p \bmod p\Lambda$. This solves Exercise 2.9.9(f).

(g) Set $\mathbf{k} = \mathbb{Z}$. Thus, the sign $\otimes$ will mean $\otimes_{\mathbb{Z}}$ in the remainder of this solution. Also, $\Lambda = \Lambda_{\mathbb{Z}}$. We define the notation $v_p\left(n\right)$ as in Exercise 2.9.6.

Let us introduce a notion from commutative algebra:

In the following, a *special Ψ-ring* will mean a pair $\left(A, \left(\varphi_n\right)_{n\in\{1,2,3,\ldots\}}\right)$, where A is a commutative ring and $\left(\varphi_n\right)_{n\in\{1,2,3,\ldots\}}$ is a family of ring endomorphisms $\varphi_n : A \to A$ of A satisfying the following properties:

- We have $\varphi_n \circ \varphi_m = \varphi_{nm}$ for any two positive integers n and m.
- We have $\varphi_1 = \mathrm{id}$.
- We have $\varphi_p\left(a\right) \equiv a^p \bmod pA$ for every $a \in A$ and every prime number p.

The tensor product of two special Ψ-rings $\left(A, \left(\varphi_n\right)_{n\in\{1,2,3,\ldots\}}\right)$ and $\left(B, \left(\psi_n\right)_{n\in\{1,2,3,\ldots\}}\right)$ is defined to be the pair $\left(A \otimes B, \left(\varphi_n \otimes \psi_n\right)_{n\in\{1,2,3,\ldots\}}\right)$. This pair $\left(A \otimes B, \left(\varphi_n \otimes \psi_n\right)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring again[678].

[678] *Proof.* We need to prove the following five statements:

Here are three examples of special Ψ-rings which we will need:

- The pair $\left(\mathbb{Z}, (\mathrm{id})_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring. (The proof of this relies on Fermat's little theorem.)
- The pair $\left(\Lambda, (\mathbf{f}_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring. (This follows from parts (a), (b), (c) and (f) of Exercise 2.9.9.)
- The pair $\left(\Lambda\otimes\Lambda, (\mathbf{f}_n\otimes\mathbf{f}_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring. (Indeed, this pair is the tensor product of the special Ψ-ring $\left(\Lambda, (\mathbf{f}_n)_{n\in\{1,2,3,\ldots\}}\right)$ with itself.)

Statement 1: The ring $A\otimes B$ is a commutative ring.

Statement 2: The family $(\varphi_n\otimes\psi_n)_{n\in\{1,2,3,\ldots\}}$ is a family of ring endomorphisms $\varphi_n\otimes\psi_n : A\otimes B\to A\otimes B$ of $A\otimes B$.

Statement 3: We have $(\varphi_n\otimes\psi_n)\circ(\varphi_m\otimes\psi_n) = \varphi_{nm}\otimes\psi_{nm}$ for any two positive integers n and m.

Statement 4: We have $\varphi_1\otimes\psi_1 = \mathrm{id}$.

Statement 5: We have $(\varphi_p\otimes\psi_p)(a)\equiv a^p \bmod p(A\otimes B)$ for every $a\in A\otimes B$ and every prime number p.

Proof of Statement 1: This is obvious.

Proof of Statement 2: The family $(\varphi_n)_{n\in\{1,2,3,\ldots\}}$ is a family of ring endomorphisms of A (since $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring). Thus, φ_n is a ring endomorphism of A for every positive integer n. Similarly, ψ_n is a ring endomorphism of B for every positive integer n. Thus, $\varphi_n\otimes\psi_n$ is a ring endomorphism of $A\otimes B$ for every positive integer n. In other words, Statement 2 holds.

Proof of Statement 3: Let n and m be positive integers. Then, $\varphi_n\circ\varphi_m = \varphi_{nm}$ (since $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring) and $\psi_n\circ\psi_m = \psi_{nm}$ (similarly). Now, $(\varphi_n\otimes\psi_n)\circ(\varphi_m\otimes\psi_n) = \underbrace{(\varphi_n\circ\varphi_m)}_{=\varphi_{nm}}\otimes\underbrace{(\psi_n\circ\psi_m)}_{=\psi_{nm}} = \varphi_{nm}\otimes\psi_{nm}$, and thus Statement 3 is proven.

Proof of Statement 4: Since $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring, we have $\varphi_1 = \mathrm{id}$. Similarly, $\psi_1 = \mathrm{id}$. Thus, $\varphi_1\otimes\psi_1 = \mathrm{id}\otimes\mathrm{id} = \mathrm{id}$. This proves Statement 4.

Proof of Statement 5: Fix a prime number p. For every commutative ring R, we introduce three pieces of notation:

- We let $\overline{R}$ denote the commutative ring R/pR.
- We let π_R denote the canonical projection $R\to R/pR$.
- We let pow_R denote the map $R\to R$ which sends every $r\in R$ to r^p. This is not a linear map in general, but when $p\cdot 1_R = 0$, the map pow_R is a ring endomorphism of R.

Now, $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring. Hence, $\varphi_p(a)\equiv a^p \bmod pA$ for every $a\in A$. In other words, $\pi_A(\varphi_p(a)) = \pi_A\left(\underbrace{a^p}_{=\mathrm{pow}_A a}\right) = \pi_A(\mathrm{pow}_A a)$ for every $a\in A$. In other words, $\pi_A\circ\varphi_p = \pi_A\circ\mathrm{pow}_A$. But $\pi_A\circ\mathrm{pow}_A = \mathrm{pow}_{\overline{A}}\circ\pi_A$ (this is just saying that taking the p-th power commutes with the projection π_A). Hence,

$$\pi_A\circ\varphi_p = \pi_A\circ\mathrm{pow}_A = \mathrm{pow}_{\overline{A}}\circ\pi_A.$$

Similarly,

$$\pi_B\circ\psi_p = \pi_B\circ\mathrm{pow}_B = \mathrm{pow}_{\overline{B}}\circ\pi_B.$$

For every commutative ring R, the ring $\overline{R}$ satisfies $p\cdot 1_{\overline{R}} = 0$, and thus $\mathrm{pow}_{\overline{R}}$ is a ring endomorphism of $\overline{R}$. Hence, $\mathrm{pow}_{\overline{A}}$, $\mathrm{pow}_{\overline{B}}$ and $\mathrm{pow}_{\overline{A\otimes B}}$ are ring endomorphisms, thus $\mathbb{Z}$-algebra endomorphisms; consequently, the tensor product $\mathrm{pow}_{\overline{A}}\otimes\mathrm{pow}_{\overline{B}}$ makes sense. Moreover, we have $\mathrm{pow}_{\overline{A}}\otimes\mathrm{pow}_{\overline{B}} = \mathrm{pow}_{\overline{A\otimes B}}$ (because both $\mathrm{pow}_{\overline{A}}\otimes\mathrm{pow}_{\overline{B}}$ and $\mathrm{pow}_{\overline{A\otimes B}}$ are ring endomorphisms of $\overline{A}\otimes\overline{B}$ sending pure tensors $\alpha\otimes\beta$ to $\alpha^p\otimes\beta^p = (\alpha\otimes\beta)^p$, and this characterizes them uniquely).

There is a canonical isomorphism $\overline{A}\otimes\overline{B}\to\overline{A\otimes B}$ (because tensoring is right-exact). We identify $\overline{A\otimes B}$ with $\overline{A}\otimes\overline{B}$ along this isomorphism. Then, $\pi_{A\otimes B} = \pi_A\otimes\pi_B$. Thus,

$$\begin{aligned}
\underbrace{\pi_{A\otimes B}}_{=\pi_A\otimes\pi_B}\circ(\varphi_p\otimes\psi_p) &= (\pi_A\otimes\pi_B)\circ(\varphi_p\otimes\psi_p) = \underbrace{(\pi_A\circ\varphi_p)}_{=\mathrm{pow}_{\overline{A}}\circ\pi_A}\otimes\underbrace{(\pi_B\circ\psi_p)}_{=\mathrm{pow}_{\overline{B}}\circ\pi_B}\\
&= \left(\mathrm{pow}_{\overline{A}}\circ\pi_A\right)\otimes\left(\mathrm{pow}_{\overline{B}}\circ\pi_B\right) = \underbrace{\left(\mathrm{pow}_{\overline{A}}\otimes\mathrm{pow}_{\overline{B}}\right)}_{=\mathrm{pow}_{\overline{A\otimes B}}}\circ\underbrace{(\pi_A\otimes\pi_B)}_{=\pi_{A\otimes B}}\\
&= \mathrm{pow}_{\overline{A\otimes B}}\circ\pi_{A\otimes B} = \pi_{A\otimes B}\circ\mathrm{pow}_{A\otimes B}\\
&\qquad\text{(since taking the p-th power commutes with the projection $\pi_{A\otimes B}$)}.
\end{aligned}$$

Hence, every $a\in A\otimes B$ satisfies $\pi_{A\otimes B}((\varphi_p\otimes\psi_p)(a)) = \pi_{A\otimes B}\left(\mathrm{pow}_{A\otimes B}(a)\right)$. In other words, every $a\in A\otimes B$ satisfies $(\varphi_p\otimes\psi_p)(a)\equiv\mathrm{pow}_{A\otimes B}(a) = a^p \bmod p(A\otimes B)$. Thus, Statement 5 is proven.

It thus follows that $\left(A\otimes B, (\varphi_n\otimes\psi_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring, qed.

Now, we will establish a pattern which we will follow in our new solutions to parts (b), (c), (d), (e) and (f) of Exercise 2.9.4. Namely, let $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right)$ be a special Ψ-ring such that the $\mathbb{Z}$-module A is free. Then, A canonically injects into $A \otimes \mathbb{Q}$. Identify A with a subring of $A \otimes \mathbb{Q}$ using this injection. Also, consider $\Lambda = \Lambda_{\mathbb{Z}}$ as a subring of $\Lambda_{\mathbb{Q}}$ as in Exercise 2.9.4. Let $f : \Lambda_{\mathbb{Q}} \to A \otimes \mathbb{Q}$ be a $\mathbb{Q}$-algebra homomorphism such that every $n \in \{1, 2, 3, \ldots\}$ satisfies $f(p_n) \in A$. We can then ask for a criterion for $f(\Lambda) \subset A$. Using Exercise 2.9.6, we can obtain such an answer:

$$\left(\begin{array}{c}\text{We have } f(\Lambda) \subset A \text{ if every positive integer } n \text{ and every}\\ \text{prime factor } p \text{ of } n \text{ satisfy } \varphi_p\left(f\left(p_{n/p}\right)\right) \equiv f(p_n) \bmod p^{v_p(n)} A\end{array}\right). \tag{13.86.14}$$

[679] (The “if” here can be extended to “if and only if”, but we do not need the “only if” part.)

Let us now give alternative solutions to parts (b), (c), (d), (e) and (f) of Exercise 2.9.4:

Alternative solution to part (b) of Exercise 2.9.4: The $\mathbb{Z}$-module $\Lambda \otimes \Lambda$ is free, and thus canonically injects into $(\Lambda \otimes \Lambda) \otimes \mathbb{Q}$. We use this identification to regard $\Lambda \otimes \Lambda$ as a subring of $(\Lambda \otimes \Lambda) \otimes \mathbb{Q}$. We also identify $\Lambda_{\mathbb{Q}} \otimes_{\mathbb{Q}} \Lambda_{\mathbb{Q}}$ with $(\Lambda \otimes \Lambda) \otimes \mathbb{Q}$. Notice that every $n \in \{1, 2, 3, \ldots\}$ satisfies $\Delta_\times(p_n) = p_n \otimes p_n \in \Lambda \otimes \Lambda$.

We need to prove that $\Delta_\times(\Lambda) \subset \Lambda \otimes_{\mathbb{Z}} \Lambda$. In other words, we need to prove that $\Delta_\times(\Lambda) \subset \Lambda \otimes \Lambda$. This will follow from (13.86.14) (applied to $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right) = \left(\Lambda \otimes \Lambda, (\mathbf{f}_n \otimes \mathbf{f}_n)_{n\in\{1,2,3,\ldots\}}\right)$ and $f = \Delta_\times$) once we have showed that every positive integer n and every prime factor p of n satisfy

$$(\mathbf{f}_p \otimes \mathbf{f}_p)\left(\Delta_\times\left(p_{n/p}\right)\right) \equiv \Delta_\times(p_n) \bmod p^{v_p(n)} (\Lambda \otimes \Lambda). \tag{13.86.15}$$

Thus, it remains to prove (13.86.15).

Let n be a positive integer, and let p be a prime factor of n. The definition of $\mathbf{f}_p\left(p_{n/p}\right)$ yields

$$\begin{aligned}\mathbf{f}_p\left(p_{n/p}\right) &= p_{n/p}\left(x_1^p, x_2^p, x_3^p, \ldots\right) = \left(x_1^{n/p}\right)^p + \left(x_2^{n/p}\right)^p + \left(x_3^{n/p}\right)^p + \cdots \\ &= x_1^n + x_2^n + x_3^n + \cdots = p_n.\end{aligned} \tag{13.86.16}$$

Now,

$$\begin{aligned}(\mathbf{f}_p \otimes \mathbf{f}_p)\left(\underbrace{\Delta_\times\left(p_{n/p}\right)}_{\substack{=p_{n/p}\otimes p_{n/p}\\ \text{(by the definition of } \Delta_\times)}}\right) &= (\mathbf{f}_p \otimes \mathbf{f}_p)\left(p_{n/p} \otimes p_{n/p}\right) = \underbrace{\mathbf{f}_p\left(p_{n/p}\right)}_{=p_n} \otimes \underbrace{\mathbf{f}_p\left(p_{n/p}\right)}_{=p_n} \\ &= p_n \otimes p_n = \Delta_\times(p_n) \qquad \text{(by the definition of } \Delta_\times).\end{aligned}$$

Hence, (13.86.15) holds. Thus, Exercise 2.9.4(b) is solved again.

Alternative solution to part (c) of Exercise 2.9.4: We identify $\mathbb{Z} \otimes \mathbb{Q}$ with $\mathbb{Q}$. Every $n \in \{1, 2, 3, \ldots\}$ satisfies $\epsilon_r(p_n) = r \in \mathbb{Z}$.

[679] *Proof of (13.86.14):* Exercise 2.9.6 can be applied to the family $(b_n)_{n\geq 1} = (f(p_n))_{n\geq 1}$ (indeed, the conditions of Exercise 2.9.6 are satisfied because $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right)$ is a special Ψ-ring). As a result, we see that the Assertions $\mathcal{C}$, $\mathcal{D}$, $\mathcal{E}$, $\mathcal{F}$, $\mathcal{G}$, $\mathcal{H}$ and $\mathcal{J}$ for $(b_n)_{n\geq 1} = (f(p_n))_{n\geq 1}$ are equivalent.

Assume that every positive integer n and every prime factor p of n satisfy $\varphi_p\left(f\left(p_{n/p}\right)\right) \equiv f(p_n) \bmod p^{v_p(n)} A$. Then, the family $(f(p_n))_{n\geq 1} \in A^{\{1,2,3,\ldots\}}$ satisfies the Assertion $\mathcal{C}$ of Exercise 2.9.6. But since Assertion $\mathcal{C}$ is equivalent to Assertion $\mathcal{J}$, this yields that the family $(f(p_n))_{n\geq 1} \in A^{\{1,2,3,\ldots\}}$ satisfies the Assertion $\mathcal{J}$ as well. In other words, there exists a ring homomorphism $\Lambda_{\mathbb{Z}} \to A$ which, for every positive integer n, sends p_n to $f(p_n)$. Let g be such a ring homomorphism. Then, $g(p_n) = f(p_n)$ for every positive integer n.

The $\mathbb{Z}$-algebra homomorphism $g : \Lambda_{\mathbb{Z}} \to A$ can be extended to a $\mathbb{Q}$-algebra homomorphism $\Lambda_{\mathbb{Z}} \otimes \mathbb{Q} \to A \otimes \mathbb{Q}$ (by base change). Since $\Lambda_{\mathbb{Z}} \otimes \mathbb{Q} \cong \Lambda_{\mathbb{Q}}$ canonically, we can regard this latter $\mathbb{Q}$-algebra homomorphism as a $\mathbb{Q}$-algebra homomorphism $\Lambda_{\mathbb{Q}} \to A \otimes \mathbb{Q}$. Let us denote this $\mathbb{Q}$-algebra homomorphism $\Lambda_{\mathbb{Q}} \to A \otimes \mathbb{Q}$ by $\widetilde{g}$. Thus, $\widetilde{g}\mid_\Lambda = g$.

Now, both f and $\widetilde{g}$ are $\mathbb{Q}$-algebra homomorphisms $\Lambda_{\mathbb{Q}} \to A \otimes \mathbb{Q}$. These homomorphisms f and $\widetilde{g}$ are equal to each other on the elements $p_1, p_2, p_3, \ldots$ of $\Lambda_{\mathbb{Q}}$ (because for every positive integer n, we have $\widetilde{g}(p_n) = \underbrace{(\widetilde{g}\mid_\Lambda)}_{=g}(p_n) = g(p_n) = f(p_n)$). Since the elements $p_1, p_2, p_3, \ldots$ generate the $\mathbb{Q}$-algebra $\Lambda_{\mathbb{Q}}$, this forces said homomorphisms f and $\widetilde{g}$ to be identical. That is, we have $f = \widetilde{g}$. Hence, $f(\Lambda) = \widetilde{g}(\Lambda) = \underbrace{(\widetilde{g}\mid_\Lambda)}_{=g}(\Lambda) = g(\Lambda) \subset A$ (since the target of g is A). This proves (13.86.14).

We need to prove that $\epsilon_r(\Lambda) \subset \mathbb{Z}$. This will follow from (13.86.14) (applied to $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right) = \left(\mathbb{Z}, (\mathrm{id})_{n\in\{1,2,3,\ldots\}}\right)$ and $f = \epsilon_r$) once we have showed that every positive integer n and every prime factor p of n satisfy

$$\mathrm{id}\left(\epsilon_r\left(p_{n/p}\right)\right) \equiv \epsilon_r(p_n) \bmod p^{v_p(n)}\mathbb{Z}.$$

But this congruence follows immediately from

$$\begin{aligned}\mathrm{id}\left(\epsilon_r\left(p_{n/p}\right)\right) = \epsilon_r\left(p_{n/p}\right) = r \qquad & \text{(by the definition of } \epsilon_r\text{)}\\ = \epsilon_r(p_n) \qquad & \text{(by the definition of } \epsilon_r\text{)}.\end{aligned}$$

Thus, Exercise 2.9.4(c) is solved again.

Alternative solution to part (d) of Exercise 2.9.4: The $\mathbb{Z}$-module Λ is free, and thus canonically injects into $\Lambda \otimes \mathbb{Q}$. We use this identification to regard Λ as a subring of $\Lambda \otimes \mathbb{Q}$. We also identify $\Lambda_{\mathbb{Q}}$ with $\Lambda \otimes \mathbb{Q}$. Notice that every $n \in \{1,2,3,\ldots\}$ satisfies $\mathbf{i}_r(p_n) = rp_n \in \Lambda$.

We need to prove that $\mathbf{i}_r(\Lambda) \subset \Lambda$. This will follow from (13.86.14) (applied to $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right) = \left(\Lambda, (\mathbf{f}_n)_{n\in\{1,2,3,\ldots\}}\right)$ and $f = \mathbf{i}_r$) once we have showed that every positive integer n and every prime factor p of n satisfy

$$\mathbf{f}_p\left(\mathbf{i}_r\left(p_{n/p}\right)\right) \equiv \mathbf{i}_r(p_n) \bmod p^{v_p(n)}\Lambda.$$

But this congruence follows from

$$\mathbf{f}_p\left(\underbrace{\mathbf{i}_r\left(p_{n/p}\right)}_{\substack{=rp_{n/p}\\ \text{(by the definition of } \mathbf{i}_r\text{)}}}\right) = \mathbf{f}_p\left(rp_{n/p}\right) = r\underbrace{\mathbf{f}_p\left(p_{n/p}\right)}_{\substack{=p_n\\ \text{(by (13.86.16))}}} = rp_n = \mathbf{i}_r(p_n) \qquad \text{(by the definition of } \mathbf{i}_r\text{)}.$$

This solves Exercise 2.9.4(d) again.

Alternative solution to part (e) of Exercise 2.9.4: The $\mathbb{Z}$-module Λ is free, and thus canonically injects into $\Lambda \otimes \mathbb{Q}$. We use this identification to regard Λ as a subring of $\Lambda \otimes \mathbb{Q}$. We also identify $\Lambda_{\mathbb{Q}}$ with $\Lambda \otimes \mathbb{Q}$.

It is easy to see that the map Sq is a $\mathbb{Q}$-algebra homomorphism[680]. Every $n \in \{1,2,3,\ldots\}$ satisfies $\mathrm{Sq}(p_n) = p_n^2 \in \Lambda$.

We need to prove that $\mathrm{Sq}(\Lambda) \subset \Lambda$. This will follow from (13.86.14) (applied to $\left(A, (\varphi_n)_{n\in\{1,2,3,\ldots\}}\right) = \left(\Lambda, (\mathbf{f}_n)_{n\in\{1,2,3,\ldots\}}\right)$ and $f = \mathrm{Sq}$) once we have showed that every positive integer n and every prime factor p of n satisfy

$$\mathbf{f}_p\left(\mathrm{Sq}\left(p_{n/p}\right)\right) \equiv \mathrm{Sq}(p_n) \bmod p^{v_p(n)}\Lambda.$$

[680] *Proof.* We need to check that $\mathrm{Sq}(ab) = (\mathrm{Sq}\, a)(\mathrm{Sq}\, b)$ for any $a \in \Lambda_{\mathbb{Q}}$ and $b \in \Lambda_{\mathbb{Q}}$. Since Sq is $\mathbb{Q}$-linear, this only needs to be checked on a basis of the $\mathbb{Q}$-module $\Lambda_{\mathbb{Q}}$. For this we use the basis $(p_\lambda)_{\lambda\in\mathrm{Par}}$ of $\Lambda_{\mathbb{Q}}$. Checking the identity $\mathrm{Sq}(ab) = (\mathrm{Sq}\, a)(\mathrm{Sq}\, b)$ on this basis amounts to proving that $\mathrm{Sq}(p_\lambda p_\mu) = (\mathrm{Sq}(p_\lambda))(\mathrm{Sq}(p_\mu))$ for any two partitions λ and μ. So let λ and μ be two partitions. It is clear that there exists a partition ν such that $p_\lambda p_\mu = p_\nu$ (indeed, this ν is the partition obtained by sorting the list $\left(\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}, \mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}\right)$ in decreasing order). Consider this ν. We have

$$\begin{aligned}\mathrm{Sq}\left(\underbrace{p_\lambda p_\mu}_{=p_\nu}\right) &= \mathrm{Sq}(p_\nu) = p_\nu^2 \qquad \text{(by the definition of Sq)}\\ &= (p_\lambda p_\mu)^2 \qquad \text{(since } p_\nu = p_\lambda p_\mu\text{)}\\ &= \underbrace{p_\lambda^2}_{\substack{=\mathrm{Sq}(p_\lambda)\\ \text{(by the definition of Sq)}}}\underbrace{p_\mu^2}_{\substack{=\mathrm{Sq}(p_\mu)\\ \text{(by the definition of Sq)}}} = (\mathrm{Sq}(p_\lambda))(\mathrm{Sq}(p_\mu)),\end{aligned}$$

which is what we wanted to prove. Thus we have checked that $\mathrm{Sq}(ab) = (\mathrm{Sq}\, a)(\mathrm{Sq}\, b)$ for any $a \in \Lambda_{\mathbb{Q}}$ and $b \in \Lambda_{\mathbb{Q}}$. Hence, Sq is a $\mathbb{Q}$-algebra homomorphism (since $\mathrm{Sq}(1) = 1$), qed.

But this congruence follows from

$$\mathbf{f}_p\left(\underbrace{\operatorname{Sq}\left(p_{n/p}\right)}_{\substack{=p_{n/p}^2\\ \text{(by the definition of Sq)}}}\right)=\mathbf{f}_p\left(p_{n/p}^2\right)=\left(\underbrace{\mathbf{f}_p\left(p_{n/p}\right)}_{\substack{=p_n\\ \text{(by (13.86.16))}}}\right)^2 \qquad \text{(since } \mathbf{f}_p \text{ is a ring homomorphism)}$$
$$=p_n^2=\operatorname{Sq}\left(p_n\right).$$

This solves Exercise 2.9.4(e) again.

Alternative solution to part (f) of Exercise 2.9.4: The $\mathbb{Z}$-module $\Lambda\otimes\Lambda$ is free, and thus canonically injects into $(\Lambda\otimes\Lambda)\otimes\mathbb{Q}$. We use this identification to regard $\Lambda\otimes\Lambda$ as a subring of $(\Lambda\otimes\Lambda)\otimes\mathbb{Q}$. We also identify $\Lambda_{\mathbb{Q}}\otimes_{\mathbb{Q}}\Lambda_{\mathbb{Q}}$ with $(\Lambda\otimes\Lambda)\otimes\mathbb{Q}$. Notice that every $n\in\{1,2,3,\ldots\}$ satisfies $\Delta_r(p_n)=\sum_{i=1}^{n-1}\binom{n}{i}p_i\otimes p_{n-i}+r\otimes p_n+p_n\otimes r\in\Lambda\otimes\Lambda$.

We need to prove that $\Delta_r(\Lambda)\subset\Lambda\otimes_{\mathbb{Z}}\Lambda$. In other words, we need to prove that $\Delta_r(\Lambda)\subset\Lambda\otimes\Lambda$. This will follow from (13.86.14) (applied to $\left(A,(\varphi_n)_{n\in\{1,2,3,\ldots\}}\right)=\left(\Lambda\otimes\Lambda,(\mathbf{f}_n\otimes\mathbf{f}_n)_{n\in\{1,2,3,\ldots\}}\right)$ and $f=\Delta_r$) once we have showed that every positive integer n and every prime factor p of n satisfy

$$(\mathbf{f}_p\otimes\mathbf{f}_p)\left(\Delta_r\left(p_{n/p}\right)\right)\equiv\Delta_r(p_n)\operatorname{mod}p^{v_p(n)}(\Lambda\otimes\Lambda). \tag{13.86.17}$$

Thus, it remains to prove (13.86.17).

Let n be a positive integer, and let p be a prime factor of n. For the sake of brevity, we denote r by p_0. Then,

$$\Delta_r(p_n)=\sum_{i=1}^{n-1}\binom{n}{i}p_i\otimes p_{n-i}+\underbrace{r}_{=p_0}\otimes p_n+p_n\otimes\underbrace{r}_{=p_0}$$
$$=\sum_{i=1}^{n-1}\binom{n}{i}p_i\otimes p_{n-i}+p_0\otimes p_n+p_n\otimes p_0=\sum_{i=0}^{n}\binom{n}{i}p_i\otimes p_{n-i}. \tag{13.86.18}$$

Applying this to n/p instead of n, we obtain

$$\Delta_r\left(p_{n/p}\right)=\sum_{i=0}^{n/p}\binom{n/p}{i}p_i\otimes p_{n/p-i}. \tag{13.86.19}$$

Now, we will need two elementary congruences for binomial coefficients:

- For any $i\in\mathbb{N}$ satisfying $p\mid i$, we have

$$\binom{n/p}{i/p}\equiv\binom{n}{i}\operatorname{mod}p^{v_p(n)}. \tag{13.86.20}$$

  (This follows from (13.85.3), applied to $q=1$ and $r=i/n$.)

- For any $i\in\mathbb{N}$ satisfying $p\nmid i$, we have

$$0\equiv\binom{n}{i}\operatorname{mod}p^{v_p(n)}. \tag{13.86.21}$$

  (This follows from (13.85.3), applied to $q=1$ and $r=i/n$, keeping in mind that $\binom{a}{b}=0$ if $b\notin\mathbb{N}$.)

Now, applying the map $\mathbf{f}_p \otimes \mathbf{f}_p$ to both sides of the equality (13.86.19), we obtain

$$\begin{aligned}
\left(\mathbf{f}_p \otimes \mathbf{f}_p\right)\left(\Delta_r\left(p_{n/p}\right)\right) &= \left(\mathbf{f}_p \otimes \mathbf{f}_p\right)\left(\sum_{i=0}^{n/p}\binom{n/p}{i} p_i \otimes p_{n/p-i}\right) \\
&= \sum_{i=0}^{n/p}\binom{n/p}{i} \underbrace{\mathbf{f}_p\left(p_i\right)}_{\substack{=\mathbf{f}_p\left(p_{pi/p}\right)=p_{pi} \\ \text{(by (13.86.16), applied to} \\ pi \text{ instead of } n)}} \otimes \underbrace{\mathbf{f}_p\left(p_{n/p-i}\right)}_{\substack{=\mathbf{f}_p\left(p_{(n-pi)/p}\right)=p_{n-pi} \\ \text{(by (13.86.16), applied to} \\ n-pi \text{ instead of } n)}} \\
&= \sum_{i=0}^{n/p}\binom{n/p}{i} p_{pi} \otimes p_{n-pi} = \sum_{i\in\{0,1,\ldots,n/p\}}\binom{n/p}{i} p_{pi} \otimes p_{n-pi} = \sum_{\substack{i\in\{0,1,\ldots,n\}; \\ p\mid i}}\binom{n/p}{i/p} p_i \otimes p_{n-i}
\end{aligned}$$

(here, we have substituted i/p for i in the sum). Comparing this with

$$\begin{aligned}
\Delta_r\left(p_n\right) &= \sum_{i=0}^{n}\binom{n}{i} p_i \otimes p_{n-i} \qquad \text{(by (13.86.18))} \\
&= \sum_{\substack{i\in\{0,1,\ldots,n\}; \\ p\mid i}} \underbrace{\binom{n}{i}}_{\substack{\equiv\binom{n/p}{i/p} \bmod p^{v_p(n)}(\Lambda\otimes\Lambda) \\ \text{(by (13.86.20))}}} p_i \otimes p_{n-i} + \sum_{\substack{i\in\{0,1,\ldots,n\}; \\ p\nmid i}} \underbrace{\binom{n}{i}}_{\substack{\equiv 0 \bmod p^{v_p(n)}(\Lambda\otimes\Lambda) \\ \text{(by (13.86.21))}}} p_i \otimes p_{n-i} \\
&\equiv \sum_{\substack{i\in\{0,1,\ldots,n\}; \\ p\mid i}}\binom{n/p}{i/p} p_i \otimes p_{n-i} + \underbrace{\sum_{\substack{i\in\{0,1,\ldots,n\}; \\ p\nmid i}} 0 p_i \otimes p_{n-i}}_{=0} \\
&= \sum_{\substack{i\in\{0,1,\ldots,n\}; \\ p\mid i}}\binom{n/p}{i/p} p_i \otimes p_{n-i} \bmod p^{v_p(n)}\left(\Lambda\otimes\Lambda\right),
\end{aligned}$$

we obtain

$$\left(\mathbf{f}_p \otimes \mathbf{f}_p\right)\left(\Delta_r\left(p_{n/p}\right)\right) \equiv \Delta_r\left(p_n\right) \bmod p^{v_p(n)}\left(\Lambda\otimes\Lambda\right).$$

Hence, (13.86.17) holds. Thus, Exercise 2.9.4(f) is solved again.

13.87. **Solution to Exercise 2.9.10.** *Solution to Exercise 2.9.10.* Let us first notice that every positive integer n satisfies

$$\text{(13.87.1)} \qquad \mathbf{v}_n\left(h_m\right) = \begin{cases} h_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} \qquad \text{for every } m \in \mathbb{N}$$

[681].

(b) Let n be a positive integer. Recall that a ring of formal power series $R\left[\left[t\right]\right]$ over a commutative ring R has a canonical topology which makes it into a topological R-algebra. Thus, in particular, $\Lambda\left[\left[t\right]\right]$ becomes a topological Λ-algebra. We shall be considering this topology when we speak of continuity.

[681] *Proof of (13.87.1):* Let n be a positive integer. Let $m \in \mathbb{N}$. We need to prove that (13.87.1) holds.

If $m \neq 0$, then m is a positive integer. Hence, if $m \neq 0$, then (13.87.1) follows immediately from the definition of $\mathbf{v}_n\left(h_m\right)$. Thus, for the rest of this proof of (13.87.1), we can WLOG assume that we don't have $m \neq 0$. Assume this.

We don't have $m \neq 0$. Thus, we have $m = 0$, so that $h_m = h_0 = 1$ and therefore $\mathbf{v}_n\left(\underbrace{h_m}_{=1}\right) = \mathbf{v}_n\left(1\right) = 1$ (since $\mathbf{v}_n$ is a $\mathbf{k}$-algebra homomorphism).

The $\mathbf{k}$-algebra homomorphism $\mathbf{v}_n : \Lambda \to \Lambda$ induces a continuous $\mathbf{k}$-algebra homomorphism $\mathbf{v}_n [[t]] : \Lambda [[t]] \to \Lambda [[t]]$ given by

$$(\mathbf{v}_n [[t]]) \left(\sum_{i \in \mathbb{N}} a_i t^i \right) = \sum_{i \in \mathbb{N}} \mathbf{v}_n (a_i) t^i \qquad \text{for all } (a_i)_{i \in \mathbb{N}} \in \Lambda^{\mathbb{N}}.$$

Consider the power series $H(t) \in \Lambda [[t]]$ and $E(t) \in \Lambda [[t]]$ defined in the proof of Proposition 2.4.1. We have

$$H(t) = 1 + h_1(\mathbf{x}) t + h_2(\mathbf{x}) t^2 + \cdots = \sum_{i \geq 0} h_i(\mathbf{x}) t^i = \sum_{i \geq 0} h_i t^i$$

and similarly $E(t) = \sum_{i \geq 0} e_i t^i$.

Substituting t^n for t in the equality $H(t) = \sum_{i \geq 0} h_i t^i$, we obtain $H(t^n) = \sum_{i \geq 0} h_i (t^n)^i$. Substituting $-t$ for t in the equality $E(t) = \sum_{i \geq 0} e_i t^i$, we obtain $E(-t) = \sum_{i \geq 0} e_i \underbrace{(-t)^i}_{=(-1)^i t^i} = \sum_{i \geq 0} (-1)^i e_i t^i$. Substituting $-t^n$ for t in the equality $E(t) = \sum_{i \geq 0} e_i t^i$, we obtain $E(-t^n) = \sum_{i \geq 0} e_i (-t^n)^i$.

Applying the map $\mathbf{v}_n [[t]]$ to both sides of the equality $H(t) = \sum_{i \geq 0} h_i t^i$, we obtain

$$\begin{aligned}
&(\mathbf{v}_n [[t]]) (H(t)) \\
&= (\mathbf{v}_n [[t]]) \left(\sum_{i \geq 0} h_i t^i \right) = \sum_{i \geq 0} \underbrace{\mathbf{v}_n (h_i)}_{\substack{= \begin{cases} h_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases} \\ \text{(by (13.87.1), applied to } m = i)}} t^i \qquad \text{(by the definition of } \mathbf{v}_n [[t]]) \\
&= \sum_{i \geq 0} \begin{cases} h_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases} \cdot t^i = \sum_{\substack{i \geq 0; \\ n \mid i}} \underbrace{\begin{cases} h_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases}}_{\substack{= h_{i/n} \\ \text{(since } n \mid i)}} \cdot t^i + \sum_{\substack{i \geq 0; \\ n \nmid i}} \underbrace{\begin{cases} h_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases}}_{\substack{= 0 \\ \text{(since } n \nmid i)}} \cdot t^i \\
&= \sum_{\substack{i \geq 0; \\ n \mid i}} h_{i/n} t^i + \underbrace{\sum_{\substack{i \geq 0; \\ n \nmid i}} 0 t^i}_{= 0} = \sum_{\substack{i \geq 0; \\ n \mid i}} h_{i/n} t^i = \sum_{i \geq 0} h_i \underbrace{t^{ni}}_{= (t^n)^i} \qquad \text{(here, we substituted } ni \text{ for } i \text{ in the sum)} \\
&= \sum_{i \geq 0} h_i (t^n)^i = H(t^n).
\end{aligned} \tag{13.87.2}$$

Also, $\begin{cases} h_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} = h_{m/n}$ (since $n \mid 0 = m$). Now,

$$\begin{aligned}
\mathbf{v}_n (h_m) = 1 = h_0 = h_{m/n} \qquad & \left(\text{since } h_{m/n} = h_0 \text{ (since } \underbrace{m}_{=0} / n = 0/n = 0) \right) \\
= \begin{cases} h_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} .
\end{aligned}$$

This proves (13.87.1).

But (2.4.3) yields $1 = E(-t) H(t)$, so that $E(-t) = \frac{1}{H(t)}$. Applying the map $\mathbf{v}_n[[t]]$ to both sides of this equality, we obtain

$$\begin{aligned}
(\mathbf{v}_n[[t]])(E(-t)) &= (\mathbf{v}_n[[t]])\left(\frac{1}{H(t)}\right) = \frac{1}{(\mathbf{v}_n[[t]])(H(t))} \qquad (\text{since } \mathbf{v}_n[[t]] \text{ is a } \mathbf{k}\text{-algebra homomorphism}) \\
&= \frac{1}{H(t^n)} \qquad (\text{by (13.87.2)}) \\
&= E(-t^n) \qquad \left(\begin{array}{c}\text{because } E(-t^n) = \dfrac{1}{H(t^n)} \text{ (this follows by substituting } t^n \\ \text{for } t \text{ in the equality } E(-t) = \dfrac{1}{H(t)})\end{array}\right) \\
&= \sum_{i \geq 0} e_i \underbrace{(-t^n)^i}_{=(-1)^i t^{ni}} = \sum_{i \geq 0} (-1)^i e_i t^{ni}. \qquad (13.87.3)
\end{aligned}$$

Now,

$$\begin{aligned}
&\sum_{i \geq 0} \begin{cases} (-1)^{i/n} e_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases} \cdot t^i \\
&= \sum_{\substack{i \geq 0; \\ n \mid i}} \underbrace{\begin{cases} (-1)^{i/n} e_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases}}_{\substack{=(-1)^{i/n} e_{i/n} \\ (\text{since } n \mid i)}} \cdot t^i + \sum_{\substack{i \geq 0; \\ n \nmid i}} \underbrace{\begin{cases} (-1)^{i/n} e_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases}}_{\substack{=0 \\ (\text{since } n \nmid i)}} \cdot t^i \\
&= \sum_{\substack{i \geq 0; \\ n \mid i}} (-1)^{i/n} e_{i/n} t^i + \underbrace{\sum_{\substack{i \geq 0; \\ n \nmid i}} 0 t^i}_{=0} = \sum_{\substack{i \geq 0; \\ n \mid i}} (-1)^{i/n} e_{i/n} t^i \\
&= \sum_{i \geq 0} (-1)^i e_i t^{ni} \qquad (\text{here, we substituted } ni \text{ for } i \text{ in the sum}) \\
&= (\mathbf{v}_n[[t]])(E(-t)) \qquad (\text{by (13.87.3)}). \qquad (13.87.4)
\end{aligned}$$

But applying the map $\mathbf{v}_n[[t]]$ to both sides of the equality $E(-t) = \sum_{i \geq 0} (-1)^i e_i t^i$, we obtain

$$\begin{aligned}
(\mathbf{v}_n[[t]])(E(-t)) &= (\mathbf{v}_n[[t]])\left(\sum_{i \geq 0} (-1)^i e_i t^i\right) = \sum_{i \geq 0} \underbrace{\mathbf{v}_n\left((-1)^i e_i\right)}_{\substack{=(-1)^i \mathbf{v}_n(e_i) \\ (\text{since } \mathbf{v}_n \text{ is } \mathbf{k}\text{-linear})}} t^i \qquad (\text{by the definition of } \mathbf{v}_n[[t]]) \\
&= \sum_{i \geq 0} (-1)^i \mathbf{v}_n(e_i) t^i.
\end{aligned}$$

Hence,

$$\sum_{i \geq 0} (-1)^i \mathbf{v}_n(e_i) t^i = (\mathbf{v}_n[[t]])(E(-t)) = \sum_{i \geq 0} \begin{cases} (-1)^{i/n} e_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases} \cdot t^i \qquad (13.87.5)$$

(by (13.87.4)).

Now, let m be a positive integer. Comparing coefficients before t^m in the equality (13.87.5), we obtain

$$(-1)^m \mathbf{v}_n(e_m) = \begin{cases} (-1)^{m/n} e_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases}.$$

Dividing this by $(-1)^m$, we obtain

$$\mathbf{v}_n(e_m) = \frac{1}{(-1)^m} \begin{cases} (-1)^{m/n} e_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} = \begin{cases} \dfrac{1}{(-1)^m} (-1)^{m/n} e_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases}$$
$$= \begin{cases} (-1)^{m-m/n} e_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases}$$

(because if $n \mid m$, then $\dfrac{1}{(-1)^m}(-1)^{m/n} = (-1)^{m/n-m} = (-1)^{m-m/n}$). This solves Exercise 2.9.10(b).

(a) Let n be a positive integer. We define the continuous $\mathbf{k}$-algebra homomorphism $\mathbf{v}_n[[t]] : \Lambda[[t]] \to [[t]]$ as in the solution of Exercise 2.9.10(a).

Consider the power series $H(t) \in \Lambda[[t]]$ defined in the proof of Proposition 2.4.1. We have $H(t) = \sum_{i\geq 0} h_i t^i$ (this can be proven just as in the solution of Exercise 2.9.10(a)), so that $H'(t) = \sum_{i\geq 1} i h_i t^{i-1}$ (by the definition of the derivative of a power series). We can also see that the equality (13.87.2) holds (this can be proven just as in the solution of Exercise 2.9.10(a)). The power series $H(t)$ is invertible (since its constant term is $h_0 = 1$).

Exercise 2.5.21 yields $\sum_{m\geq 0} p_{m+1} t^m = \dfrac{H'(t)}{H(t)}$, so that

$$\frac{H'(t)}{H(t)} = \sum_{m\geq 0} p_{m+1} t^m = \sum_{i\geq 1} p_i t^{i-1} \qquad \text{(here, we substituted } i \text{ for } m+1 \text{ in the sum)}.$$

Multiplying this equality with t, we obtain

$$t \cdot \frac{H'(t)}{H(t)} = t \cdot \sum_{i\geq 1} p_i t^{i-1} = \sum_{i\geq 1} p_i \underbrace{t t^{i-1}}_{=t^i} = \sum_{i\geq 1} p_i t^i.$$

Multiplying this equality with $H(t)$, we obtain

$$t \cdot H'(t) = H(t) \cdot \sum_{i\geq 1} p_i t^i.$$

Hence,

$$H(t) \cdot \sum_{i\geq 1} p_i t^i = t \cdot \underbrace{H'(t)}_{=\sum_{i\geq 1} i h_i t^{i-1}} = t \cdot \sum_{i\geq 1} i h_i t^{i-1} = \sum_{i\geq 1} i h_i \underbrace{t t^{i-1}}_{=t^i} = \sum_{i\geq 1} i h_i t^i. \tag{13.87.6}$$

Substituting t^n for t in this equality, we obtain

$$H(t^n) \cdot \sum_{i\geq 1} p_i (t^n)^i = \sum_{i\geq 0} i h_i (t^n)^i. \tag{13.87.7}$$

Applying the map $\mathbf{v}_n[[t]]$ to both sides of the equality (13.87.6), we obtain

$$\begin{aligned}
&(\mathbf{v}_n[[t]])\left(H(t)\cdot\sum_{i\geq1}p_it^i\right)\\
&=(\mathbf{v}_n[[t]])\left(\sum_{i\geq1}ih_it^i\right)=\sum_{i\geq1}i\underbrace{(\mathbf{v}_n[[t]])(h_i)}_{\substack{=\mathbf{v}_n(h_i)\\ \text{(by the definition of }\mathbf{v}_n[[t]])}}\underbrace{(\mathbf{v}_n[[t]])\left(t^i\right)}_{\substack{=t^i\\ \text{(by the definition of }\mathbf{v}_n[[t]])}}\\
&\qquad\qquad\text{(since $\mathbf{v}_n[[t]]$ is a continuous $\mathbf{k}$-algebra homomorphism)}\\
&=\sum_{i\geq1}i\underbrace{\mathbf{v}_n(h_i)}_{\substack{=\begin{cases}h_{i/n}, & \text{if } n\mid i;\\ 0, & \text{if } n\nmid i\end{cases}\\ \text{(by the definition of }\mathbf{v}_n)}}t^i\\
&=\sum_{i\geq1}i\begin{cases}h_{i/n}, & \text{if } n\mid i;\\ 0, & \text{if } n\nmid i\end{cases}\cdot t^i=\sum_{\substack{i\geq1;\\ n\mid i}}i\underbrace{\begin{cases}h_{i/n}, & \text{if } n\mid i;\\ 0, & \text{if } n\nmid i\end{cases}}_{\substack{=h_{i/n}\\ \text{(since } n\mid i)}}\cdot t^i+\sum_{\substack{i\geq1;\\ n\nmid i}}i\underbrace{\begin{cases}h_{i/n}, & \text{if } n\mid i;\\ 0, & \text{if } n\nmid i\end{cases}}_{\substack{=0\\ \text{(since } n\nmid i)}}\cdot t^i\\
&=\sum_{\substack{i\geq1;\\ n\mid i}}ih_{i/n}t^i+\underbrace{\sum_{\substack{i\geq1;\\ n\nmid i}}0t^i}_{=0}=\sum_{\substack{i\geq1;\\ n\mid i}}ih_{i/n}t^i=\sum_{\substack{i\geq0;\\ n\mid i}}ih_{i/n}t^i\\
&\qquad\qquad\left(\text{since }\sum_{\substack{i\geq0;\\ n\mid i}}ih_{i/n}t^i=\sum_{\substack{i\geq1;\\ n\mid i}}ih_{i/n}t^i+\underbrace{0h_{0/n}t^0}_{=0}=\sum_{\substack{i\geq1;\\ n\mid i}}ih_{i/n}t^i\right)\\
&=\sum_{i\geq0}nih_i\underbrace{t^{ni}}_{=(t^n)^i}\qquad\qquad\text{(here, we substituted ni for i in the sum)}\\
&=\sum_{i\geq0}nih_i\left(t^n\right)^i=n\underbrace{\sum_{i\geq0}ih_i\left(t^n\right)^i}_{\substack{=H(t^n)\cdot\sum_{i\geq1}p_i(t^n)^i\\ \text{(by (13.87.7))}}}=n\cdot H\left(t^n\right)\cdot\sum_{i\geq1}p_i\left(t^n\right)^i=H\left(t^n\right)\cdot n\cdot\sum_{i\geq1}p_i\left(t^n\right)^i.
\end{aligned}$$

Compared with

$$\begin{aligned}
&(\mathbf{v}_n[[t]])\left(H(t)\cdot\sum_{i\geq1}p_it^i\right)\\
&=\underbrace{(\mathbf{v}_n[[t]])(H(t))}_{\substack{=H(t^n)\\ \text{(by (13.87.2))}}}\cdot(\mathbf{v}_n[[t]])\left(\sum_{i\geq1}p_it^i\right)\qquad\qquad\text{(since $\mathbf{v}_n[[t]]$ is a $\mathbf{k}$-algebra homomorphism)}\\
&=H\left(t^n\right)\cdot(\mathbf{v}_n[[t]])\left(\sum_{i\geq1}p_it^i\right),
\end{aligned}$$

this becomes

$$H\left(t^n\right)\cdot n\cdot\sum_{i\geq1}p_i\left(t^n\right)^i=H\left(t^n\right)\cdot(\mathbf{v}_n[[t]])\left(\sum_{i\geq1}p_it^i\right).$$

We can divide both sides of this equality by $H\left(t^{n}\right)$ (since $H\left(t^{n}\right)$ is invertible[682]). As a result, we obtain

$$n\cdot\sum_{i\geq 1}p_{i}\left(t^{n}\right)^{i}=\left(\mathbf{v}_{n}\left[\left[t\right]\right]\right)\left(\sum_{i\geq 1}p_{i}t^{i}\right)=\sum_{i\geq 1}\underbrace{\left(\mathbf{v}_{n}\left[\left[t\right]\right]\right)\left(p_{i}\right)}_{\substack{=\mathbf{v}_{n}\left(p_{i}\right)\\ \text{(by the definition of }\mathbf{v}_{n}[[t]])}}\underbrace{\left(\mathbf{v}_{n}\left[\left[t\right]\right]\right)\left(t^{i}\right)}_{\substack{=t^{i}\\ \text{(by the definition of }\mathbf{v}_{n}[[t]])}}$$

$$\text{(since }\mathbf{v}_{n}\left[\left[t\right]\right]\text{ is a continuous }\mathbf{k}\text{-algebra homomorphism)}$$

$$=\sum_{i\geq 1}\mathbf{v}_{n}\left(p_{i}\right)t^{i}. \tag{13.87.8}$$

On the other hand,

$$\begin{aligned}
&\sum_{i\geq 1}\begin{cases}np_{i/n}, & \text{if } n\mid i;\\ 0, & \text{if } n\nmid i\end{cases}\cdot t^{i}\\
&=\sum_{\substack{i\geq 1;\\ n\mid i}}\underbrace{\begin{cases}np_{i/n}, & \text{if } n\mid i;\\ 0, & \text{if } n\nmid i\end{cases}}_{\substack{=np_{i/n}\\ \text{(since } n\mid i)}}\cdot t^{i}+\sum_{\substack{i\geq 1;\\ n\nmid i}}\underbrace{\begin{cases}np_{i/n}, & \text{if } n\mid i;\\ 0, & \text{if } n\nmid i\end{cases}}_{\substack{=0\\ \text{(since } n\nmid i)}}\cdot t^{i}\\
&=\sum_{\substack{i\geq 1;\\ n\mid i}}np_{i/n}t^{i}+\underbrace{\sum_{\substack{i\geq 1;\\ n\nmid i}}0t^{i}}_{=0}=\sum_{\substack{i\geq 1;\\ n\mid i}}np_{i/n}t^{i}\\
&=\sum_{i\geq 1}np_{i}\underbrace{t^{ni}}_{=\left(t^{n}\right)^{i}}\\
&\qquad\text{(here, we have substituted } ni \text{ for } i \text{ in the sum)}\\
&=\sum_{i\geq 1}np_{i}\left(t^{n}\right)^{i}=n\cdot\sum_{i\geq 1}p_{i}\left(t^{n}\right)^{i}\\
&=\sum_{i\geq 1}\mathbf{v}_{n}\left(p_{i}\right)t^{i}\qquad\text{(by (13.87.8))}.
\end{aligned}\tag{13.87.9}$$

Now, let m be a positive integer. Comparing coefficients before t^{m} in the equality (13.87.9), we obtain

$$\begin{cases}np_{m/n}, & \text{if } n\mid m;\\ 0, & \text{if } n\nmid m\end{cases}=\mathbf{v}_{n}\left(p_{m}\right).$$

This solves Exercise 2.9.10(a).

(c) Fix two positive integers n and m. We need to prove that $\mathbf{v}_{n}\circ\mathbf{v}_{m}=\mathbf{v}_{nm}$. But both $\mathbf{v}_{n}\circ\mathbf{v}_{m}$ and $\mathbf{v}_{nm}$ are $\mathbf{k}$-algebra homomorphisms (since $\mathbf{v}_{n}$, $\mathbf{v}_{m}$ and $\mathbf{v}_{nm}$ are $\mathbf{k}$-algebra homomorphisms).

Let us now show that

$$\left(\mathbf{v}_{n}\circ\mathbf{v}_{m}\right)\left(h_{r}\right)=\mathbf{v}_{nm}\left(h_{r}\right)\qquad\text{for every positive integer } r. \tag{13.87.10}$$

[682] *Proof.* We know that the power series $H\left(t\right)$ is invertible. That is, there exists a power series $A\left(t\right)\in\Lambda\left[\left[t\right]\right]$ such that $A\left(t\right)\cdot H\left(t\right)=1$. Consider this A. Substituting t^{n} for t in the equality $A\left(t\right)\cdot H\left(t\right)=1$, we obtain $A\left(t^{n}\right)\cdot H\left(t^{n}\right)=1$. Hence, the power series $H\left(t^{n}\right)$ is invertible (and its inverse is $A\left(t^{n}\right)$), qed.

Proof of (13.87.10): Let r be a positive integer. If $m \nmid r$, then (13.87.10) holds[683]. Thus, for the rest of this proof, we can WLOG assume that we don't have $m \nmid r$. Assume this.

We have $m \mid r$ (since we don't have $m \nmid r$). Thus, r/m is a positive integer. By the definition of $\mathbf{v}_m$, we have $\mathbf{v}_m(h_r) = \begin{cases} h_{r/m}, & \text{if } m \mid r; \\ 0, & \text{if } m \nmid r \end{cases} = h_{r/m}$ (since $m \mid r$). Now,

$$\begin{aligned}
(\mathbf{v}_n \circ \mathbf{v}_m)(h_r) &= \mathbf{v}_n \left(\underbrace{\mathbf{v}_m(h_r)}_{=h_{r/m}} \right) = \mathbf{v}_n\left(h_{r/m}\right) \\
&= \begin{cases} h_{(r/m)/n}, & \text{if } n \mid r/m; \\ 0, & \text{if } n \nmid r/m \end{cases} \qquad \text{(by the definition of } \mathbf{v}_n\text{)} \\
&= \begin{cases} h_{(r/m)/n}, & \text{if } nm \mid r; \\ 0, & \text{if } nm \nmid r \end{cases} \\
&\qquad \left(\begin{array}{c} \text{since the condition } n \mid r/m \text{ is equivalent to the condition } nm \mid r, \\ \text{and since the condition } n \nmid r/m \text{ is equivalent to the condition } nm \nmid r \end{array} \right) \\
&= \begin{cases} h_{r/(nm)}, & \text{if } nm \mid r; \\ 0, & \text{if } nm \nmid r \end{cases} \qquad \left(\text{since } (r/m)/n = r/(nm)\right).
\end{aligned}$$

Compared with

$$\mathbf{v}_{nm}(h_r) = \begin{cases} h_{r/(nm)}, & \text{if } nm \mid r; \\ 0, & \text{if } nm \nmid r \end{cases} \qquad \left(\text{by the definition of } \mathbf{v}_{nm}\right),$$

this yields $(\mathbf{v}_n \circ \mathbf{v}_m)(h_r) = \mathbf{v}_{nm}(h_r)$. This proves (13.87.10).

Now, recall that the family $(h_r)_{r\geq 1}$ generates the $\mathbf{k}$-algebra Λ (according to Proposition 2.4.1). In other words, $(h_r)_{r\geq 1}$ is a generating set of the $\mathbf{k}$-algebra Λ. The two $\mathbf{k}$-algebra homomorphisms $\mathbf{v}_n \circ \mathbf{v}_m$ and $\mathbf{v}_{nm}$ are equal to each other on this generating set (according to (13.87.10)), and therefore must be identical (because if two $\mathbf{k}$-algebra homomorphisms from the same domain are equal to each other on a generating set of their domain, then these two homomorphisms must be identical). In other words, $\mathbf{v}_n \circ \mathbf{v}_m = \mathbf{v}_{nm}$. This solves Exercise 2.9.10(c).

(d) For every positive integer r, we have

$$\begin{aligned}
\mathbf{v}_1(h_r) &= \begin{cases} h_{r/1}, & \text{if } 1 \mid r; \\ 0, & \text{if } 1 \nmid r \end{cases} \qquad \left(\text{by the definition of } \mathbf{v}_1\right) \\
&= h_{r/1} \qquad (\text{since } 1 \mid r) \\
&= h_r = \operatorname{id}(h_r). \qquad \qquad (13.87.11)
\end{aligned}$$

Now, recall that the family $(h_r)_{r\geq 1}$ generates the $\mathbf{k}$-algebra Λ (according to Proposition 2.4.1). In other words, $(h_r)_{r\geq 1}$ is a generating set of the $\mathbf{k}$-algebra Λ. The two $\mathbf{k}$-algebra homomorphisms $\mathbf{v}_1$ and id are equal to each other on this generating set (according to (13.87.11)), and therefore must be identical (because if two $\mathbf{k}$-algebra homomorphisms from the same domain are equal to each other on a generating set of their domain, then these two homomorphisms must be identical). In other words, $\mathbf{v}_1 = \operatorname{id}$. This solves Exercise 2.9.10(d).

(e) Fix a positive integer n. We need to show that $\mathbf{v}_n : \Lambda \to \Lambda$ is a Hopf algebra homomorphism.

[683] *Proof.* Assume that $m \nmid r$. Then, $nm \nmid r$ (because otherwise, we would have $nm \mid r$, and therefore $m \mid nm \mid r$, which would contradict $m \nmid r$).

By the definition of $\mathbf{v}_m$, we have $\mathbf{v}_m(h_r) = \begin{cases} h_{r/m}, & \text{if } m \mid r; \\ 0, & \text{if } m \nmid r \end{cases} = 0$ (since $m \nmid r$). By the definition of $\mathbf{v}_{nm}$, we have $\mathbf{v}_{nm}(h_r) = \begin{cases} h_{r/(nm)}, & \text{if } nm \mid r; \\ 0, & \text{if } nm \nmid r \end{cases} = 0$ (since $nm \nmid r$). Now, $(\mathbf{v}_n \circ \mathbf{v}_m)(h_r) = \mathbf{v}_n \left(\underbrace{\mathbf{v}_m(h_r)}_{=0} \right) = \mathbf{v}_n(0) = 0$ (since $\mathbf{v}_n$ is $\mathbf{k}$-linear). Compared with $\mathbf{v}_{nm}(h_r) = 0$, this yields $(\mathbf{v}_n \circ \mathbf{v}_m)(h_r) = \mathbf{v}_{nm}(h_r)$. Hence, (13.87.10) holds is proven under the assumption that $m \nmid r$. Qed.

We know that $\mathbf{v}_n : \Lambda \to \Lambda$ is a $\mathbf{k}$-algebra homomorphism. Thus, $\mathbf{v}_n \otimes \mathbf{v}_n : \Lambda \otimes \Lambda \to \Lambda \otimes \Lambda$ is a $\mathbf{k}$-algebra homomorphism. Also, $\Delta : \Lambda \to \Lambda \otimes \Lambda$ is a $\mathbf{k}$-algebra homomorphism (due to the axioms of a bialgebra, since Λ is a bialgebra). Hence, $\Delta \circ \mathbf{v}_n$ and $(\mathbf{v}_n \otimes \mathbf{v}_n) \circ \Delta$ are $\mathbf{k}$-algebra homomorphisms.

For every $q \in \mathbb{N}$, we have

$$\Delta\left(h_q\right) = \sum_{i \in \{0,1,\ldots,q\}} h_i \otimes h_{q-i}. \tag{13.87.12}$$

[684]. Furthermore, for every $q \in \mathbb{N}$, we have

$$\mathbf{v}_n\left(h_{nq}\right) = h_q \tag{13.87.13}$$

[685].

Now, we shall prove that

$$\left(\Delta \circ \mathbf{v}_n\right)\left(h_r\right) = \left(\left(\mathbf{v}_n \otimes \mathbf{v}_n\right) \circ \Delta\right)\left(h_r\right) \qquad \text{for every positive integer } r. \tag{13.87.14}$$

Proof of (13.87.14): Let r be a positive integer. We need to prove (13.87.14).

Let us first notice that

$$\left(\mathbf{v}_n \otimes \mathbf{v}_n\right)\left(h_i \otimes h_{r-i}\right) = 0 \qquad \text{for every } i \in \{0,1,\ldots,r\} \text{ which does not satisfy } (n \mid i \text{ and } n \mid r-i) \tag{13.87.15}$$

[686]. In particular,

$$\left(\mathbf{v}_n \otimes \mathbf{v}_n\right)\left(h_i \otimes h_{r-i}\right) = 0 \qquad \text{for every } i \in \{0,1,\ldots,r\} \text{ satisfying } n \nmid i \tag{13.87.16}$$

[687].

---

[684] *Proof of (13.87.12):* Let $q \in \mathbb{N}$. Then, Proposition 2.3.6(iii) (applied to q instead of n) yields

$$\Delta\left(h_q\right) = \sum_{i+j=q} h_i \otimes h_j = \sum_{i \in \{0,1,\ldots,q\}} h_i \otimes h_{q-i}$$

(here, we have substituted $(i, q-i)$ for (i,j) in the sum), qed.

[685] *Proof of (13.87.13):* Let $q \in \mathbb{N}$. Applying (13.87.1) to nq instead of m, we obtain

$$\mathbf{v}_n\left(h_{nq}\right) = \begin{cases} h_{(nq)/n}, & \text{if } n \mid nq; \\ 0, & \text{if } n \nmid nq \end{cases} = h_{(nq)/n} \qquad (\text{since } n \mid nq)$$
$$= h_q,$$

qed.

[686] *Proof of (13.87.15):* Let $i \in \{0,1,\ldots,r\}$ be such that we don't have $(n \mid i$ and $n \mid r-i)$. If $n \nmid i$, then

$$\left(\mathbf{v}_n \otimes \mathbf{v}_n\right)\left(h_i \otimes h_{r-i}\right) = \underbrace{\mathbf{v}_n\left(h_i\right)}_{\substack{= \begin{cases} h_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases} \\ \text{(by (13.87.1), applied to } m=i)}} \otimes \mathbf{v}_n\left(h_{r-i}\right) = \underbrace{\begin{cases} h_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases}}_{\substack{=0 \\ (\text{since } n \nmid i)}} \otimes \mathbf{v}_n\left(h_{r-i}\right)$$
$$= 0 \otimes \mathbf{v}_n\left(h_{r-i}\right) = 0.$$

Hence, if $n \nmid i$, then (13.87.15) is proven. Thus, for the rest of this proof of (13.87.15), we can WLOG assume that we don't have $n \nmid i$. Assume this.

We have $n \mid i$ (since we don't have $n \nmid i$). Hence, we don't have $n \mid r-i$ (because otherwise, we would have $(n \mid i$ and $n \mid r-i)$, which would contradict the fact that we don't have $(n \mid i$ and $n \mid r-i)$). In other words, we have $n \nmid r-i$. Now,

$$\left(\mathbf{v}_n \otimes \mathbf{v}_n\right)\left(h_i \otimes h_{r-i}\right) = \mathbf{v}_n\left(h_i\right) \otimes \underbrace{\mathbf{v}_n\left(h_{r-i}\right)}_{\substack{= \begin{cases} h_{(r-i)/n}, & \text{if } n \mid r-i; \\ 0, & \text{if } n \nmid r-i \end{cases} \\ \text{(by (13.87.1), applied to } m=r-i)}} = \mathbf{v}_n\left(h_i\right) \otimes \underbrace{\begin{cases} h_{(r-i)/n}, & \text{if } n \mid r-i; \\ 0, & \text{if } n \nmid r-i \end{cases}}_{\substack{=0 \\ (\text{since } n \nmid r-i)}}$$
$$= \mathbf{v}_n\left(h_i\right) \otimes 0 = 0.$$

This proves (13.87.15).

[687] *Proof of (13.87.16):* Let $i \in \{0,1,\ldots,r\}$ be such that $n \nmid i$. Then, we don't have $n \mid i$. Hence, we don't have $(n \mid i$ and $n \mid r-i)$. Thus, (13.87.16) follows from (13.87.15), qed.

Let us now assume that $n \nmid r$. Then, (13.87.1) (applied to $m = r$) yields $\mathbf{v}_n \left(h_r\right) = \begin{cases} h_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases} = 0$ (since $n \nmid r$), so that $\left(\Delta \circ \mathbf{v}_n\right)\left(h_r\right) = \Delta \left(\underbrace{\mathbf{v}_n \left(h_r\right)}_{=0} \right) = \Delta\left(0\right) = 0$. Also,

$$\left(\mathbf{v}_n \otimes \mathbf{v}_n\right)\left(h_i \otimes h_{r-i}\right) = 0 \qquad \text{for every } i \in \{0,1,\ldots,r\} \tag{13.87.17}$$

[688]. Now,

$$\begin{aligned} \left(\left(\mathbf{v}_n \otimes \mathbf{v}_n\right) \circ \Delta\right)\left(h_r\right) &= \left(\mathbf{v}_n \otimes \mathbf{v}_n\right) \left(\underbrace{\Delta\left(h_r\right)}_{\substack{=\sum_{i\in\{0,1,\ldots,r\}} h_i \otimes h_{r-i} \\ \text{(by (13.87.12), applied to } q=r\text{)}}} \right) = \left(\mathbf{v}_n \otimes \mathbf{v}_n\right) \left(\sum_{i\in\{0,1,\ldots,r\}} h_i \otimes h_{r-i} \right) \\ &= \sum_{i\in\{0,1,\ldots,r\}} \underbrace{\left(\mathbf{v}_n \otimes \mathbf{v}_n\right)\left(h_i \otimes h_{r-i}\right)}_{\substack{=0 \\ \text{(by (13.87.17))}}} \qquad \text{(since the map } \mathbf{v}_n \otimes \mathbf{v}_n \text{ is } \mathbf{k}\text{-linear)} \\ &= \sum_{i\in\{0,1,\ldots,r\}} 0 = 0. \end{aligned}$$

Compared to $\left(\Delta \circ \mathbf{v}_n\right)\left(h_r\right) = 0$, this yields $\left(\Delta \circ \mathbf{v}_n\right)\left(h_r\right) = \left(\left(\mathbf{v}_n \otimes \mathbf{v}_n\right) \circ \Delta\right)\left(h_r\right)$. In other words, (13.87.14) holds.

Now, let us forget that we assumed that $n \nmid r$. We thus have proven that (13.87.14) holds under the assumption that $n \nmid r$. Hence, for the rest of the proof of (13.87.14), we can WLOG assume that we don't have $n \nmid r$. Assume this.

We have $n \mid r$ (since we don't have $n \nmid r$). Hence, r/n is a positive integer. Denote this positive integer r/n by s. Then, $s = r/n$, so that $r = ns$. The equality (13.87.1) (applied to $m = r$) yields $\mathbf{v}_n\left(h_r\right) = \begin{cases} h_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases} = h_{r/n}$ (since $n \mid r$), and we have

$$\left(\Delta \circ \mathbf{v}_n\right)\left(h_r\right) = \Delta \left(\underbrace{\mathbf{v}_n\left(h_r\right)}_{\substack{=h_{r/n}=h_s \\ \text{(since } r/n=s\text{)}}} \right) = \Delta\left(h_s\right) = \sum_{i\in\{0,1,\ldots,s\}} h_i \otimes h_{s-i} \tag{13.87.18}$$

(by (13.87.12), applied to $q = s$).

[688] *Proof of (13.87.17):* Let $i \in \{0,1,\ldots,r\}$.

Assume (for the sake of contradiction) that ($n \mid i$ and $n \mid r-i$). Then, $i \equiv 0 \mod n$ (since $n \mid i$) and $r \equiv i \mod n$ (since $n \mid r-i$). Hence, $r \equiv i \equiv 0 \mod n$, so that $n \mid r$. This contradicts $n \nmid r$. This contradiction shows that our assumption (that ($n \mid i$ and $n \mid r-i$)) was wrong. Hence, we do not have ($n \mid i$ and $n \mid r-i$). Thus, (13.87.17) follows from (13.87.15), qed.

On the other hand,

$$\begin{aligned}
\left(\left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\circ\Delta\right)\left(h_r\right) &= \left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\left(\underbrace{\Delta\left(h_r\right)}_{\substack{=\sum_{i\in\{0,1,\ldots,r\}} h_i\otimes h_{r-i}\\ \text{(by (13.87.12), applied to } q=r\text{)}}}\right) = \left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\left(\sum_{i\in\{0,1,\ldots,r\}} h_i\otimes h_{r-i}\right)\\
&= \sum_{i\in\{0,1,\ldots,r\}} \left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\left(h_i\otimes h_{r-i}\right) \qquad \text{(since the map } \mathbf{v}_n\otimes\mathbf{v}_n \text{ is } \mathbf{k}\text{-linear)}\\
&= \sum_{\substack{i\in\{0,1,\ldots,r\};\\ n\mid i}} \underbrace{\left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\left(h_i\otimes h_{r-i}\right)}_{=\mathbf{v}_n\left(h_i\right)\otimes\mathbf{v}_n\left(h_{r-i}\right)} + \sum_{\substack{i\in\{0,1,\ldots,r\};\\ n\nmid i}} \underbrace{\left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\left(h_i\otimes h_{r-i}\right)}_{\substack{=0\\ \text{(by (13.87.16))}}}\\
&= \sum_{\substack{i\in\{0,1,\ldots,r\};\\ n\mid i}} \mathbf{v}_n\left(h_i\right)\otimes\mathbf{v}_n\left(h_{r-i}\right) + \underbrace{\sum_{\substack{i\in\{0,1,\ldots,r\};\\ n\nmid i}} 0}_{=0} = \sum_{\substack{i\in\{0,1,\ldots,r\};\\ n\mid i}} \mathbf{v}_n\left(h_i\right)\otimes\mathbf{v}_n\left(h_{r-i}\right)\\
&= \underbrace{\sum_{i\in\{0,1,\ldots,r/n\}}}_{\substack{=\sum_{i\in\{0,1,\ldots,s\}}\\ \text{(since } r/n=s\text{)}}} \mathbf{v}_n\left(h_{ni}\right)\otimes\mathbf{v}_n\left(\underbrace{h_{r-ni}}_{\substack{=h_{n(s-i)}\\ \text{(since } r-ni=n(s-i)\\ \text{(because } r=ns=ni+n(s-i)\text{))}}}\right)\\
&\qquad \text{(here, we have substituted } ni \text{ for } i \text{ in the sum)}\\
&= \sum_{i\in\{0,1,\ldots,s\}} \underbrace{\mathbf{v}_n\left(h_{ni}\right)}_{\substack{=h_i\\ \text{(by (13.87.13), applied}\\ \text{to } q=i\text{)}}} \otimes \underbrace{\mathbf{v}_n\left(h_{n(s-i)}\right)}_{\substack{=h_{s-i}\\ \text{(by (13.87.13), applied}\\ \text{to } q=s-i\text{)}}} = \sum_{i\in\{0,1,\ldots,s\}} h_i\otimes h_{s-i}.
\end{aligned}$$

Compared with (13.87.18), this yields $\left(\Delta\circ\mathbf{v}_n\right)\left(h_r\right) = \left(\left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\circ\Delta\right)\left(h_r\right)$. Thus, (13.87.14) is proven.

Now, recall that the family $\left(h_r\right)_{r\geq 1}$ generates the $\mathbf{k}$-algebra Λ (according to Proposition 2.4.1). In other words, $\left(h_r\right)_{r\geq 1}$ is a generating set of the $\mathbf{k}$-algebra Λ. The two $\mathbf{k}$-algebra homomorphisms $\Delta\circ\mathbf{v}_n$ and $\left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\circ\Delta$ are equal to each other on this generating set (according to (13.87.14)), and therefore must be identical (because if two $\mathbf{k}$-algebra homomorphisms from the same domain are equal to each other on a generating set of their domain, then these two homomorphisms must be identical). In other words, $\Delta\circ\mathbf{v}_n = \left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\circ\Delta$.

One can similarly check that $\epsilon\circ\mathbf{v}_n = \epsilon$. We can now conclude that the map $\mathbf{v}_n$ is a $\mathbf{k}$-coalgebra homomorphism (since it is $\mathbf{k}$-linear and satisfies $\Delta\circ\mathbf{v}_n = \left(\mathbf{v}_n\otimes\mathbf{v}_n\right)\circ\Delta$ and $\epsilon\circ\mathbf{v}_n = \epsilon$), therefore a $\mathbf{k}$-bialgebra homomorphism (since it also is a $\mathbf{k}$-algebra homomorphism), and therefore a Hopf algebra homomorphism (by Corollary 1.4.27). This solves Exercise 2.9.10(e).

(f) Recall first that $\left(h_\lambda\right)_{\lambda\in\mathrm{Par}}$ and $\left(m_\lambda\right)_{\lambda\in\mathrm{Par}}$ are mutually dual bases with respect to the Hall inner product on Λ (according to Corollary 2.5.17(a)). Thus,

$$\left(m_\lambda, h_\mu\right) = \delta_{\lambda,\mu} \qquad \text{for any two partitions } \lambda \text{ and } \mu. \tag{13.87.19}$$

Let us introduce a notation: For every weak composition λ and every positive integer s, let $\lambda\left\{s\right\}$ denote the weak composition $\left(s\lambda_1, s\lambda_2, s\lambda_3, \ldots\right)$, where λ is written in the form $\left(\lambda_1,\lambda_2,\lambda_3,\ldots\right)$. Notice that if λ is a partition and s is a positive integer, then $\lambda\left\{s\right\}$ is a partition as well, and satisfies

$$\ell\left(\lambda\left\{s\right\}\right) = \ell\left(\lambda\right). \tag{13.87.20}$$

We have

$$\mathbf{f}_n m_\lambda = m_{\lambda\{n\}} \qquad \text{for every partition } \lambda \tag{13.87.21}$$

[689].

We need to prove that the maps $\mathbf{f}_n : \Lambda \to \Lambda$ and $\mathbf{v}_n : \Lambda \to \Lambda$ are adjoint with respect to the Hall inner product on Λ. In other words, we need to prove that

$$(\mathbf{f}_n a, b) = (a, \mathbf{v}_n b) \qquad \text{for any } a \in \Lambda \text{ and } b \in \Lambda. \tag{13.87.28}$$

Proof of (13.87.28): Fix $a \in \Lambda$ and $b \in \Lambda$.

[689] *Proof of (13.87.21):* Let λ be a partition. Write λ in the form $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$. By the definition of m_λ, we have $m_\lambda = \sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^\alpha$. But the definition of $\mathbf{f}_n$ yields

$$\mathbf{f}_n m_\lambda = \underbrace{m_\lambda}_{=\sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^\alpha} (x_1^n, x_2^n, x_3^n, \ldots) = \left(\sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^\alpha \right) (x_1^n, x_2^n, x_3^n, \ldots) = \sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^\alpha (x_1^n, x_2^n, x_3^n, \ldots). \tag{13.87.22}$$

But every weak composition α satisfies

$$\mathbf{x}^\alpha (x_1^n, x_2^n, x_3^n, \ldots) = \mathbf{x}^{\alpha\{n\}}. \tag{13.87.23}$$

(*Proof of (13.87.23):* Let α be a weak composition. Write α as $(\alpha_1, \alpha_2, \alpha_3, \ldots)$. Then, $\alpha\{n\} = (n\alpha_1, n\alpha_2, n\alpha_3, \ldots)$ (by the definition of $\alpha\{n\}$). Thus, $\mathbf{x}^{\alpha\{n\}} = x_1^{n\alpha_1} x_2^{n\alpha_2} x_3^{n\alpha_3} \cdots$ (by the definition of $\mathbf{x}^{\alpha\{n\}}$). On the other hand, $\mathbf{x}^\alpha = x_1^{\alpha_1} x_2^{\alpha_2} x_3^{\alpha_3} \cdots$ (by the definition of $\mathbf{x}^\alpha$), so that

$$\underbrace{\mathbf{x}^\alpha}_{=x_1^{\alpha_1} x_2^{\alpha_2} x_3^{\alpha_3} \cdots} (x_1^n, x_2^n, x_3^n, \ldots) = \left(x_1^{\alpha_1} x_2^{\alpha_2} x_3^{\alpha_3} \cdots \right) (x_1^n, x_2^n, x_3^n, \ldots) = (x_1^n)^{\alpha_1} (x_2^n)^{\alpha_2} (x_3^n)^{\alpha_3} \cdots = x_1^{n\alpha_1} x_2^{n\alpha_2} x_3^{n\alpha_3} \cdots = \mathbf{x}^{\alpha\{n\}}.$$

Thus, (13.87.23) is proven.)

Now, (13.87.22) becomes

$$\mathbf{f}_n m_\lambda = \sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \underbrace{\mathbf{x}^\alpha (x_1^n, x_2^n, x_3^n, \ldots)}_{\substack{=\mathbf{x}^{\alpha\{n\}} \\ \text{(by (13.87.23))}}} = \sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^{\alpha\{n\}}. \tag{13.87.24}$$

On the other hand, for every weak composition α and every permutation $\sigma \in \mathfrak{S}_{(\infty)}$, we have

$$\sigma(\alpha\{n\}) = (\sigma\alpha)\{n\}. \tag{13.87.25}$$

(*Proof of (13.87.25):* Let α be a weak composition. Let $\sigma \in \mathfrak{S}_{(\infty)}$. Write α as $(\alpha_1, \alpha_2, \alpha_3, \ldots)$. Then, $\alpha\{n\} = (n\alpha_1, n\alpha_2, n\alpha_3, \ldots)$ (by the definition of $\alpha\{n\}$), so that $\sigma(\alpha\{n\}) = \left(n\alpha_{\sigma^{-1}(1)}, n\alpha_{\sigma^{-1}(2)}, n\alpha_{\sigma^{-1}(3)}, \ldots \right)$. But $\sigma\alpha = \left(\alpha_{\sigma^{-1}(1)}, \alpha_{\sigma^{-1}(2)}, \alpha_{\sigma^{-1}(3)}, \ldots \right)$ (since $\alpha = (\alpha_1, \alpha_2, \alpha_3, \ldots)$) and thus $(\sigma\alpha)\{n\} = \left(n\alpha_{\sigma^{-1}(1)}, n\alpha_{\sigma^{-1}(2)}, n\alpha_{\sigma^{-1}(3)}, \ldots \right)$ (by the definition of $(\sigma\alpha)\{n\}$). Compared with $\sigma(\alpha\{n\}) = \left(n\alpha_{\sigma^{-1}(1)}, n\alpha_{\sigma^{-1}(2)}, n\alpha_{\sigma^{-1}(3)}, \ldots \right)$, this yields $\sigma(\alpha\{n\}) = (\sigma\alpha)\{n\}$. This proves (13.87.25).)

Now,

$$\alpha\{n\} \in \mathfrak{S}_{(\infty)}(\lambda\{n\}) \qquad \text{for every } \alpha \in \mathfrak{S}_{(\infty)}\lambda. \tag{13.87.26}$$

(*Proof of (13.87.26):* Let $\alpha \in \mathfrak{S}_{(\infty)}\lambda$. Then, there exists a $\sigma \in \mathfrak{S}_{(\infty)}$ such that $\alpha = \sigma\lambda$. Consider this σ. Then, (13.87.25) (applied to λ instead of α) yields that $\sigma(\lambda\{n\}) = (\sigma\lambda)\{n\}$. Compared with $\underbrace{\alpha}_{=\sigma\lambda}\{n\} = (\sigma\lambda)\{n\}$, this yields $\alpha\{n\} = \underbrace{\sigma}_{\in \mathfrak{S}_{(\infty)}} (\lambda\{n\}) \in \mathfrak{S}_{(\infty)}(\lambda\{n\})$. Thus, (13.87.26) is proven.)

Also,

$$\text{every element of } \mathfrak{S}_{(\infty)}(\lambda\{n\}) \text{ has the form } \alpha\{n\} \text{ for some } \alpha \in \mathfrak{S}_{(\infty)}\lambda. \tag{13.87.27}$$

(*Proof of (13.87.27):* Let β be an element of $\mathfrak{S}_{(\infty)}(\lambda\{n\})$. Then, there exists a $\sigma \in \mathfrak{S}_{(\infty)}$ such that $\beta = \sigma(\lambda\{n\})$. Consider this σ. Now, $\underbrace{\sigma}_{\in \mathfrak{S}_{(\infty)}} \lambda \in \mathfrak{S}_{(\infty)}\lambda$. Also, (13.87.25) (applied to λ instead of α) yields that $\sigma(\lambda\{n\}) = (\sigma\lambda)\{n\}$. Hence, $\beta = \sigma(\lambda\{n\}) = (\sigma\lambda)\{n\}$. Therefore, β has the form $\alpha\{n\}$ for some $\alpha \in \mathfrak{S}_{(\infty)}\lambda$ (namely, for $\alpha = \sigma\lambda$). Let us now forget that we fixed β. We thus have shown that every element β of $\mathfrak{S}_{(\infty)}(\lambda\{n\})$ has the form $\alpha\{n\}$ for some $\alpha \in \mathfrak{S}_{(\infty)}\lambda$. In other words, we have proven (13.87.27).)

Now, the map

$$\mathfrak{S}_{(\infty)}\lambda \to \mathfrak{S}_{(\infty)}(\lambda\{n\}),$$
$$\alpha \mapsto \alpha\{n\}$$

is well-defined (according to (13.87.26)). This map is injective (because any weak composition α can be uniquely reconstructed from $\alpha\{n\}$) and surjective (due to (13.87.27)); therefore, this map is bijective.

Now, (13.87.24) becomes

$$\mathbf{f}_n m_\lambda = \sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^{\alpha\{n\}} = \sum_{\alpha \in \mathfrak{S}_{(\infty)}(\lambda\{n\})} \mathbf{x}^\alpha$$

Recall that $(m_\lambda)_{\lambda\in\operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, in proving (13.87.28), we can WLOG assume that a is an element of this basis $(m_\lambda)_{\lambda\in\operatorname{Par}}$ (because the equality (13.87.28) is $\mathbf{k}$-linear in a). Assume this. Thus, a is an element of the basis $(m_\lambda)_{\lambda\in\operatorname{Par}}$. In other words, there exists a $\mu \in \operatorname{Par}$ such that $a = m_\mu$. Consider this μ. We have $\mathbf{f}_n \underbrace{a}_{=m_\mu} = \mathbf{f}_n m_\mu = m_{\mu\{n\}}$ (by (13.87.21), applied to $\lambda = \mu$).

Recall that $(h_\lambda)_{\lambda\in\operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, in proving (13.87.28), we can WLOG assume that b is an element of this basis $(h_\lambda)_{\lambda\in\operatorname{Par}}$ (because the equality (13.87.28) is $\mathbf{k}$-linear in b). Assume this. Thus, b is an element of the basis $(h_\lambda)_{\lambda\in\operatorname{Par}}$. In other words, there exists a $\nu \in \operatorname{Par}$ such that $b = h_\nu$. Consider this ν. We have

$$\left(\underbrace{\mathbf{f}_n a}_{=m_{\mu\{n\}}}, \underbrace{b}_{=h_\nu}\right) = \left(m_{\mu\{n\}}, h_\nu\right) = \delta_{\mu\{n\},\nu} \tag{13.87.29}$$

(by (13.87.19), applied to $\mu\{n\}$ and ν instead of λ and μ).

Let us write the partition ν in the form $(\nu_1, \nu_2, \nu_3, \ldots)$. Then, $\nu = \left(\nu_1, \nu_2, \ldots, \nu_{\ell(\nu)}\right)$, so that $h_\nu = h_{\nu_1} h_{\nu_2} \cdots h_{\nu_{\ell(\nu)}}$ (by the definition of h_ν).

Let us first assume that

$$(\text{there exists an } i \in \{1,2,3,\ldots\} \text{ such that } n \nmid \nu_i)\,. \tag{13.87.30}$$

Then, $\mathbf{v}_n(h_\nu) = 0$ [690]. Also, $\mu\{n\} \neq \nu$ [691], so that $\delta_{\mu\{n\},\nu} = 0$. Thus, (13.87.29) becomes $(\mathbf{f}_n a, b) = \delta_{\mu\{n\},\nu} = 0$. Compared with $\left(a, \mathbf{v}_n \underbrace{b}_{=h_\nu}\right) = \left(a, \underbrace{\mathbf{v}_n(h_\nu)}_{=0}\right) = (a, 0) = 0$ (since the Hall inner product is $\mathbf{k}$-bilinear), this yields $(\mathbf{f}_n a, b) = (a, \mathbf{v}_n b)$. Thus, (13.87.28) holds.

Now, let us forget that we assumed that (13.87.30) holds. We thus have proven (13.87.28) under the assumption that (13.87.30) holds. Hence, for the rest of our proof of (13.87.28), we can WLOG assume that (13.87.30) does not hold. Assume this.

(here, we substituted α for $\alpha\{n\}$ in the sum, since the map

$$\mathfrak{S}_{(\infty)}\lambda \to \mathfrak{S}_{(\infty)}(\lambda\{n\}),$$
$$\alpha \mapsto \alpha\{n\}$$

is bijective). Compared with

$$m_{\lambda\{n\}} = \sum_{\alpha\in\mathfrak{S}_{(\infty)}(\lambda\{n\})} \mathbf{x}^\alpha \qquad \left(\text{by the definition of } m_{\lambda\{n\}}\right),$$

this yields $\mathbf{f}_n m_\lambda = m_{\lambda\{n\}}$. Thus, (13.87.21) is proven.

[690] *Proof.* There exists an $i \in \{1,2,3,\ldots\}$ such that $n \nmid \nu_i$. Consider this i. We have $n \nmid \nu_i$, thus $\nu_i \neq 0$, and therefore ν_i is a positive integer. Hence, $i \leq \ell(\nu)$, so that $i \in \{1,2,\ldots,\ell(\nu)\}$. Also, the definition of $\mathbf{v}_n$ yields $\mathbf{v}_n(h_{\nu_i}) = \begin{cases} h_{\nu_i/n}, & \text{if } n \mid \nu_i; \\ 0, & \text{if } n \nmid \nu_i \end{cases} = 0$ (since $n \nmid \nu_i$). But

$$h_\nu = h_{\nu_1} h_{\nu_2} \cdots h_{\nu_{\ell(\nu)}} = \left(h_{\nu_1} h_{\nu_2} \cdots h_{\nu_{i-1}}\right) h_{\nu_i} \left(h_{\nu_{i+1}} h_{\nu_{i+2}} \cdots h_{\nu_{\ell(\nu)}}\right) \qquad (\text{since } i \in \{1,2,\ldots,\ell(\nu)\})\,.$$

Applying the map $\mathbf{v}_n$ to both sides of this equality, we obtain

$$\begin{aligned}\mathbf{v}_n(h_\nu) &= \mathbf{v}_n\left(\left(h_{\nu_1} h_{\nu_2} \cdots h_{\nu_{i-1}}\right) h_{\nu_i} \left(h_{\nu_{i+1}} h_{\nu_{i+2}} \cdots h_{\nu_{\ell(\nu)}}\right)\right) \\ &= \mathbf{v}_n\left(h_{\nu_1} h_{\nu_2} \cdots h_{\nu_{i-1}}\right) \cdot \underbrace{\mathbf{v}_n(h_{\nu_i})}_{=0} \cdot \mathbf{v}_n\left(h_{\nu_{i+1}} h_{\nu_{i+2}} \cdots h_{\nu_{\ell(\nu)}}\right) \qquad (\text{since } \mathbf{v}_n \text{ is a } \mathbf{k}\text{-algebra homomorphism}) \\ &= 0,\end{aligned}$$

qed.

[691] *Proof.* Assume the contrary. Thus, $\mu\{n\} = \nu$. Let us write the partition μ in the form $(\mu_1, \mu_2, \mu_3, \ldots)$. Then, $\mu\{n\} = (n\mu_1, n\mu_2, n\mu_3, \ldots)$ (by the definition of $\mu\{n\}$). Hence, $(\nu_1, \nu_2, \nu_3, \ldots) = \nu = \mu\{n\} = (n\mu_1, n\mu_2, n\mu_3, \ldots)$. Thus, every positive integer j satisfies $\nu_j = n\mu_j$.

But (13.87.30) yields that there exists an $i \in \{1,2,3,\ldots\}$ such that $n \nmid \nu_i$. Consider this i. Now, recall that every positive integer j satisfies $\nu_j = n\mu_j$. Applied to $j = i$, this yields $\nu_i = n\mu_i$, so that $n \mid \nu_i$. This contradicts $n \nmid \nu_i$. This contradiction proves that our assumption was wrong, qed.

We have assumed that (13.87.30) does not hold. In other words, there exists no $i \in \{1, 2, 3, \ldots\}$ such that $n \nmid \nu_i$. In other words,

$$\text{every } i \in \{1, 2, 3, \ldots\} \text{ satisfies } n \mid \nu_i. \tag{13.87.31}$$

Thus, ν_i / n is a nonnegative integer for every $i \in \{1, 2, 3, \ldots\}$. These nonnegative integers satisfy $\nu_1/n \geq \nu_2/n \geq \nu_3/n \geq \cdots$ (since $\nu_1 \geq \nu_2 \geq \nu_3 \geq \cdots$ (since $(\nu_1, \nu_2, \nu_3, \ldots) = \nu$ is a partition)) and $(\nu_i/n = 0 \text{ for all sufficiently high } i)$ (since $(\nu_i = 0 \text{ for all sufficiently high } i)$ (since $(\nu_1, \nu_2, \nu_3, \ldots) = \nu$ is a partition)). Hence, $(\nu_1/n, \nu_2/n, \nu_3/n, \ldots)$ is a partition. Let us denote this partition by κ. We have $\kappa\{n\} = \nu$ [692] and thus $\ell(\kappa) = \ell(\nu)$ [693]. We have $\mathbf{v}_n(h_\nu) = h_\kappa$ [694] and thus

$$\left(\underbrace{a}_{=m_\mu}, \mathbf{v}_n \underbrace{b}_{=h_\nu}\right) = \left(m_\mu, \underbrace{\mathbf{v}_n(h_\nu)}_{=h_\kappa}\right) = (m_\mu, h_\kappa) = \delta_{\mu,\kappa} \tag{13.87.32}$$

(by (13.87.19), applied to μ and κ instead of λ and μ).

Now, let us write the partition μ in the form $(\mu_1, \mu_2, \mu_3, \ldots)$. Then, $\mu\{n\} = (n\mu_1, n\mu_2, n\mu_3, \ldots)$ (by the definition of $\mu\{n\}$).

Now, we have the following equivalence of assertions:

$$\begin{aligned}
&(\mu\{n\} = \nu) \\
\Longleftrightarrow\ & ((n\mu_1, n\mu_2, n\mu_3, \ldots) = (\nu_1, \nu_2, \nu_3, \ldots)) \\
&\qquad (\text{since } \mu\{n\} = (n\mu_1, n\mu_2, n\mu_3, \ldots) \text{ and } \nu = (\nu_1, \nu_2, \nu_3, \ldots)) \\
\Longleftrightarrow\ & (\text{every } i \in \{1, 2, 3, \ldots\} \text{ satisfies } n\mu_i = \nu_i) \\
\Longleftrightarrow\ & (\text{every } i \in \{1, 2, 3, \ldots\} \text{ satisfies } \mu_i = \nu_i/n) \\
\Longleftrightarrow\ & ((\mu_1, \mu_2, \mu_3, \ldots) = (\nu_1/n, \nu_2/n, \nu_3/n, \ldots)) \\
\Longleftrightarrow\ & (\mu = \kappa) \qquad (\text{since } (\mu_1, \mu_2, \mu_3, \ldots) = \mu \text{ and } (\nu_1/n, \nu_2/n, \nu_3/n, \ldots) = \kappa).
\end{aligned} \tag{13.87.33}$$

[692] *Proof.* We have $\kappa = (\nu_1/n, \nu_2/n, \nu_3/n, \ldots)$. Hence, the definition of $\kappa\{n\}$ yields $\kappa\{n\} = (n(\nu_1/n), n(\nu_2/n), n(\nu_3/n), \ldots) = (\nu_1, \nu_2, \nu_3, \ldots) = \nu$, qed.

[693] *Proof.* Applying (13.87.20) to κ and n instead of λ and s, we obtain $\ell(\kappa\{n\}) = \ell(\kappa)$. Since $\kappa\{n\} = \nu$, this rewrites as $\ell(\nu) = \ell(\kappa)$, qed.

[694] *Proof.* We have $\kappa = (\nu_1/n, \nu_2/n, \nu_3/n, \ldots)$ and therefore $\kappa = \left(\nu_1/n, \nu_2/n, \ldots, \nu_{\ell(\kappa)}/n\right)$. Since $\ell(\kappa) = \ell(\nu)$, this rewrites as $\kappa = \left(\nu_1/n, \nu_2/n, \ldots, \nu_{\ell(\nu)}/n\right)$. Hence, the definition of h_κ yields $h_\kappa = h_{\nu_1/n} h_{\nu_2/n} \cdots h_{\nu_{\ell(\nu)}/n} = \prod_{i=1}^{\ell(\nu)} h_{\nu_i/n}$.

On the other hand, $\nu = \left(\nu_1, \nu_2, \ldots, \nu_{\ell(\nu)}\right)$, so that the definition of h_ν yields $h_\nu = h_{\nu_1} h_{\nu_2} \cdots h_{\nu_{\ell(\nu)}} = \prod_{i=1}^{\ell(\nu)} h_{\nu_i}$. Applying the map $\mathbf{v}_n$ to both sides of this equality, we obtain

$$\begin{aligned}
\mathbf{v}_n(h_\nu) = \mathbf{v}_n\left(\prod_{i=1}^{\ell(\nu)} h_{\nu_i}\right) &= \prod_{i=1}^{\ell(\nu)} \underbrace{\mathbf{v}_n(h_{\nu_i})}_{\substack{=\begin{cases} h_{\nu_i/n}, & \text{if } n \mid \nu_i; \\ 0, & \text{if } n \nmid \nu_i \end{cases} \\ \text{(by (13.87.1), applied to } m = \nu_i)}} \qquad (\text{since } \mathbf{v}_n \text{ is a } \mathbf{k}\text{-algebra homomorphism}) \\
&= \prod_{i=1}^{\ell(\nu)} \underbrace{\begin{cases} h_{\nu_i/n}, & \text{if } n \mid \nu_i; \\ 0, & \text{if } n \nmid \nu_i \end{cases}}_{\substack{=h_{\nu_i/n} \\ \text{(since } n \mid \nu_i \text{ (by (13.87.31)))}}} = \prod_{i=1}^{\ell(\nu)} h_{\nu_i/n} = h_\kappa
\end{aligned}$$

(since $h_\kappa = \prod_{i=1}^{\ell(\nu)} h_{\nu_i/n}$), qed.

But (13.87.29) becomes

$$\begin{aligned}
(\mathbf{f}_n a, b) &= \delta_{\mu\{n\},\nu} = \begin{cases} 1, & \text{if } \mu\{n\} = \nu; \\ 0, & \text{otherwise} \end{cases} \qquad \left(\text{by the definition of } \delta_{\mu\{n\},\nu}\right) \\
&= \begin{cases} 1, & \text{if } \mu = \kappa; \\ 0, & \text{otherwise} \end{cases} \qquad \left(\text{since } \mu\{n\} = \nu \text{ is equivalent to } \mu = \kappa \text{ (by (13.87.33))}\right) \\
&= \delta_{\mu,\kappa} \qquad \left(\text{since } \delta_{\mu,\kappa} = \begin{cases} 1, & \text{if } \mu = \kappa; \\ 0, & \text{otherwise} \end{cases} \text{ (by the definition of } \delta_{\mu,\kappa})\right) \\
&= (a, \mathbf{v}_n b) \qquad (\text{by (13.87.32)}) .
\end{aligned}$$

Thus, (13.87.28) is proven. As we know, this completes the solution of Exercise 2.9.10(f).

(g) Our solution to Exercise 2.9.10(g) shall proceed in three steps:

- *Step 1:* proving that Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Q}$.
- *Step 2:* proving that Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Z}$.
- *Step 3:* proving that Exercise 2.9.10(g) holds in the general case.

Let us now get to the details of these three steps:

Step 1: We shall prove that Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Q}$.

Indeed, assume that $\mathbf{k} = \mathbb{Q}$. We know that $\mathbf{f}_n$ is a $\mathbf{k}$-algebra homomorphism (due to Exercise 2.9.9(a)), and that $\mathbf{v}_n$ is a $\mathbf{k}$-algebra homomorphism. Hence, $\mathbf{v}_n \circ \mathbf{f}_n$ is a $\mathbf{k}$-algebra homomorphism. Also, $\underbrace{\operatorname{id}_\Lambda \star \operatorname{id}_\Lambda \star \cdots \star \operatorname{id}_\Lambda}_{n \text{ times}}$ is a $\mathbf{k}$-algebra homomorphism (due to Exercise 1.5.11(b), applied to $H = \Lambda$, $A = \Lambda$, $k = n$ and $f_i = \operatorname{id}_\Lambda$). In other words, $\operatorname{id}_\Lambda^{\star n}$ is a $\mathbf{k}$-algebra homomorphism.

Let r be a positive integer. We shall now show that $(\mathbf{v}_n \circ \mathbf{f}_n)(p_r) = \operatorname{id}_\Lambda^{\star n}(p_r)$.

Indeed, it is easy to see that

$$\operatorname{id}_\Lambda^{\star a}(p_r) = a p_r \qquad \text{for every } a \in \mathbb{N} \tag{13.87.34}$$

[695]. Applied to $a = n$, this yields $\operatorname{id}_\Lambda^{\star n}(p_r) = np_r$. But the definition of $\mathbf{f}_n(p_r)$ yields

$$\begin{aligned}
\mathbf{f}_n(p_r) &= p_r\left(x_1^n, x_2^n, x_3^n, \ldots\right) \\
&= \left(x_1^n\right)^r + \left(x_2^n\right)^r + \left(x_3^n\right)^r + \cdots \qquad \left(\text{since } p_r = x_1^r + x_2^r + x_3^r + \cdots\right) \\
&= x_1^{rn} + x_2^{rn} + x_3^{rn} + \ldots = p_{rn}.
\end{aligned} \tag{13.87.35}$$

Hence,

$$\begin{aligned}
\left(\mathbf{v}_n \circ \mathbf{f}_n\right)(p_r) &= \mathbf{v}_n\left(\underbrace{\mathbf{f}_n(p_r)}_{=p_{rn}}\right) = \mathbf{v}_n(p_{rn}) \\
&= \begin{cases} np_{rn/n}, & \text{if } n \mid rn; \\ 0, & \text{if } n \nmid rn \end{cases} \qquad (\text{by Exercise 2.9.10(a), applied to } m = rn) \\
&= np_{rn/n} \qquad (\text{since } n \mid rn) \\
&= np_r = \operatorname{id}_\Lambda^{\star n}(p_r)
\end{aligned}$$

(since $\operatorname{id}_\Lambda^{\star n}(p_r) = np_r$).

Now, let us forget that we fixed r. We thus have proven that

$$\left(\mathbf{v}_n \circ \mathbf{f}_n\right)(p_r) = \operatorname{id}_\Lambda^{\star n}(p_r) \qquad \text{for every positive integer } r. \tag{13.87.36}$$

We have assumed that $\mathbf{k} = \mathbb{Q}$. Thus, $\mathbb{Q}$ is a subring of $\mathbf{k}$. Hence, the elements $p_1, p_2, p_3, \ldots$ of Λ generate the $\mathbf{k}$-algebra Λ (due to Proposition 2.4.1). But $\mathbf{v}_n \circ \mathbf{f}_n$ and $\operatorname{id}_\Lambda^{\star n}$ are two $\mathbf{k}$-algebra homomorphisms from Λ. These two homomorphisms $\mathbf{v}_n \circ \mathbf{f}_n$ and $\operatorname{id}_\Lambda^{\star n}$ are equal to each other on each of the elements $p_1, p_2, p_3, \ldots$ (due to (13.87.36)), and therefore are identical (because if two $\mathbf{k}$-algebra homomorphisms with one and the same domain are equal to each other on a generating set of the domain, then these homomorphisms must be identical). In other words, $\mathbf{v}_n \circ \mathbf{f}_n = \operatorname{id}_\Lambda^{\star n}$. Thus, Exercise 2.9.10(g) is solved under the assumption that $\mathbf{k} = \mathbb{Q}$. Our Step 1 is complete.

Step 2: We shall prove that Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Z}$.

Indeed, let us first consider the general case, without any assumptions on $\mathbf{k}$.

[695] *Proof of (13.87.34):* We shall prove (13.87.34) by induction over a:

Induction base: We have $\epsilon(p_r) = 0$ (since r is positive). Now, $\underbrace{\operatorname{id}_\Lambda^{\star 0}}_{=u\circ\epsilon}(p_r) = (u \circ \epsilon)(p_r) = u\left(\underbrace{\epsilon(p_r)}_{=0}\right) = u(0) = 0$, so that $\operatorname{id}_\Lambda^{\star 0}(p_r) = 0 = 0p_r$. In other words, (13.87.34) holds for $a = 0$. This completes the induction base.

Induction step: Let A be a positive integer. Assume that (13.87.34) holds for $a = A - 1$. We now need to show that (13.87.34) holds for $a = A$.

We know that (13.87.34) holds for $a = A-1$. In other words, $\operatorname{id}_\Lambda^{\star(A-1)}(p_r) = (A-1)p_r$. Now, recall that $\Delta p_r = 1 \otimes p_r + p_r \otimes 1$ (by Proposition 2.3.6(i), applied to r instead of n). On the other hand, $\operatorname{id}_\Lambda^{\star(A-1)}$ is a $\mathbf{k}$-algebra homomorphism (in fact, this is shown in the same way as we have shown that $\operatorname{id}_\Lambda^{\star n}$ is a $\mathbf{k}$-algebra homomorphism), so that we have $\operatorname{id}_\Lambda^{\star(A-1)}(1) = 1$. Now, $\operatorname{id}_\Lambda^{\star A} = \operatorname{id}_\Lambda^{\star(A-1)} \star \operatorname{id}_\Lambda = m \circ \left(\operatorname{id}_\Lambda^{\star(A-1)} \otimes \operatorname{id}_\Lambda\right) \circ \Delta$ (by the definition of convolution). Applying both sides of this equality to p_r, we obtain

$$\begin{aligned}
\operatorname{id}_\Lambda^{\star A}(p_r) &= \left(m \circ \left(\operatorname{id}_\Lambda^{\star(A-1)} \otimes \operatorname{id}_\Lambda\right) \circ \Delta\right)(p_r) = m\left(\left(\operatorname{id}_\Lambda^{\star(A-1)} \otimes \operatorname{id}_\Lambda\right) \underbrace{(\Delta p_r)}_{=1\otimes p_r + p_r \otimes 1}\right) \\
&= m\left(\underbrace{\left(\operatorname{id}_\Lambda^{\star(A-1)} \otimes \operatorname{id}_\Lambda\right)(1 \otimes p_r + p_r \otimes 1)}_{=\operatorname{id}_\Lambda^{\star(A-1)}(1)\otimes \operatorname{id}_\Lambda(p_r) + \operatorname{id}_\Lambda^{\star(A-1)}(p_r)\otimes \operatorname{id}_\Lambda(1)}\right) \\
&= m\left(\operatorname{id}_\Lambda^{\star(A-1)}(1) \otimes \operatorname{id}_\Lambda(p_r) + \operatorname{id}_\Lambda^{\star(A-1)}(p_r) \otimes \operatorname{id}_\Lambda(1)\right) \\
&= \underbrace{\operatorname{id}_\Lambda^{\star(A-1)}(1)}_{=1} \cdot \underbrace{\operatorname{id}_\Lambda(p_r)}_{=p_r} + \underbrace{\operatorname{id}_\Lambda^{\star(A-1)}(p_r)}_{=(A-1)p_r} \cdot \underbrace{\operatorname{id}_\Lambda(1)}_{=1} = p_r + (A-1)p_r = Ap_r.
\end{aligned}$$

Thus, (13.87.34) holds for $a = A$. This completes the induction step, so that (13.87.34) is proven.

We shall now formalize the intuitive concept that the constructions relevant to Exercise 2.9.10(g) (the Hopf algebra Λ, its elements m_λ, p_λ, e_λ etc., and the maps $\mathbf{v}_n$, $\mathbf{f}_n$ and $\operatorname{id}_\Lambda^{\star n}$) are "functorial" with respect to the base ring $\mathbf{k}$. This is chiefly a matter of introducing notations:

- We denote the $\mathbf{k}$-algebra $\Lambda = \Lambda_\mathbf{k}$ by $\Lambda^{[\mathbf{k}]}$. (This is just a minor change of notation that serves to make it more similar to the notations $\mathbf{f}_n^{[\mathbf{k}]}$, $\mathbf{v}_n^{[\mathbf{k}]}$ and $m_\lambda^{[\mathbf{k}]}$ further below.)
- If $\mathbf{m}$ and $\mathbf{n}$ are two commutative rings, and $\varphi : \mathbf{m} \to \mathbf{n}$ is a ring homomorphism, then φ canonically induces a ring homomorphism $\Lambda^{[\mathbf{m}]} \to \Lambda^{[\mathbf{n}]}$. [696] We denote this latter homomorphism by $\Lambda^{[\varphi]}$.

  Notice that while $\Lambda^{[\mathbf{k}]}$ denotes a ring, $\Lambda^{[\varphi]}$ denotes a map. This might look confusing, but it makes sense from the viewpoint of category theory: There is a functor from the category of commutative rings to itself, which sends every commutative ring $\mathbf{k}$ to $\Lambda^{[\mathbf{k}]}$, and every morphism $\varphi : \mathbf{m} \to \mathbf{n}$ of commutative rings to $\Lambda^{[\varphi]}$. Unsurprisingly, this functor is denoted by Λ.
- A ring homomorphism $\varphi : \mathbf{m} \to \mathbf{n}$ also induces a ring homomorphism $\Lambda^{[\mathbf{m}]} \otimes_\mathbf{m} \Lambda^{[\mathbf{m}]} \to \Lambda^{[\mathbf{n}]} \otimes_\mathbf{n} \Lambda^{[\mathbf{n}]}$ [697]. This makes $\Lambda \otimes \Lambda$ into a functor of $\mathbf{k}$.
- For every partition λ, we shall denote the monomial symmetric function $m_\lambda \in \Lambda$ by $m_\lambda^{[\mathbf{k}]}$. This notation makes the dependency of m_λ on the base ring $\mathbf{k}$ more explicit, and thus allows us to talk about these elements defined over several different base rings at the same time (without the danger of confusing them). Of course, the element m_λ does not "really" depend on $\mathbf{k}$, in the sense that it is defined in the same way for every $\mathbf{k}$. This entails that for any two commutative rings $\mathbf{m}$ and $\mathbf{n}$ and any ring homomorphism $\varphi : \mathbf{m} \to \mathbf{n}$, we have
$$m_\lambda^{[\mathbf{n}]} = \Lambda^{[\varphi]} \left(m_\lambda^{[\mathbf{m}]} \right) \tag{13.87.37}$$
  for every partition λ.
- We shall denote the homomorphism $\mathbf{f}_n : \Lambda \to \Lambda$ by $\mathbf{f}_n^{[\mathbf{k}]}$. This notation makes the dependency of $\mathbf{f}_n$ on the base ring $\mathbf{k}$ more explicit.

  The definition of $\mathbf{f}_n$ was functorial in $\mathbf{k}$. Thus, for any two commutative rings $\mathbf{m}$ and $\mathbf{n}$ and any ring homomorphism $\varphi : \mathbf{m} \to \mathbf{n}$, we have
$$\mathbf{f}_n^{[\mathbf{n}]} \circ \Lambda^{[\varphi]} = \Lambda^{[\varphi]} \circ \mathbf{f}_n^{[\mathbf{m}]} \tag{13.87.38}$$
  as maps from $\Lambda^{[\mathbf{m}]}$ to $\Lambda^{[\mathbf{n}]}$.
- Similarly, we shall denote the homomorphism $\mathbf{v}_n : \Lambda \to \Lambda$ by $\mathbf{v}_n^{[\mathbf{k}]}$. This homomorphism is again defined in a way that is functorial in $\mathbf{k}$. Thus, for any two commutative rings $\mathbf{m}$ and $\mathbf{n}$ and any ring homomorphism $\varphi : \mathbf{m} \to \mathbf{n}$, we have
$$\mathbf{v}_n^{[\mathbf{n}]} \circ \Lambda^{[\varphi]} = \Lambda^{[\varphi]} \circ \mathbf{v}_n^{[\mathbf{m}]} \tag{13.87.39}$$
  as maps from $\Lambda^{[\mathbf{m}]}$ to $\Lambda^{[\mathbf{n}]}$.
- Notice that the Hopf algebra structure on Λ is functorial in $\mathbf{k}$. [698] As a consequence, for any two commutative rings $\mathbf{m}$ and $\mathbf{n}$ and any ring homomorphism $\varphi : \mathbf{m} \to \mathbf{n}$, we have
$$\operatorname{id}_{\Lambda_\mathbf{n}}^{\star n} \circ \Lambda^{[\varphi]} = \Lambda^{[\varphi]} \circ \operatorname{id}_{\Lambda_\mathbf{m}}^{\star n} \tag{13.87.40}$$
  as maps from $\Lambda^{[\mathbf{m}]}$ to $\Lambda^{[\mathbf{n}]}$.
- For every commutative ring $\mathbf{k}$, there exists a canonical (and unique) ring homomorphism $\mathbb{Z} \to \mathbf{k}$. Denote this homomorphism by $\rho_\mathbf{k}$.

[696] In fact, this ring homomorphism $\Lambda^{[\mathbf{m}]} \to \Lambda^{[\mathbf{n}]}$ can be defined by taking the ring homomorphism $\varphi[[\mathbf{x}]] : \mathbf{m}[[\mathbf{x}]] \to \mathbf{n}[[\mathbf{x}]]$ canonically induced by φ and restricting it to the subring $\Lambda^{[\mathbf{m}]}$ of $\mathbf{m}[[\mathbf{x}]]$.

[697] There are several ways to define this homomorphism. One of them is to define it as the $\mathbf{m}$-module homomorphism $\Lambda^{[\mathbf{m}]} \otimes_\mathbf{m} \Lambda^{[\mathbf{m}]} \to \Lambda^{[\mathbf{n}]} \otimes_\mathbf{n} \Lambda^{[\mathbf{n}]}$ canonically induced by the $\mathbf{m}$-bilinear map
$$\Lambda^{[\mathbf{m}]} \times \Lambda^{[\mathbf{m}]} \to \Lambda^{[\mathbf{n}]} \otimes_\mathbf{n} \Lambda^{[\mathbf{n}]},$$
$$(a, b) \mapsto \left(\Lambda^{[\varphi]}(a) \right) \otimes_\mathbf{n} \left(\Lambda^{[\varphi]}(b) \right).$$
(Here, $\Lambda^{[\mathbf{n}]} \otimes_\mathbf{n} \Lambda^{[\mathbf{n}]}$ is an $\mathbf{m}$-module because the ring homomorphism $\varphi : \mathbf{m} \to \mathbf{n}$ makes $\mathbf{n}$ into an $\mathbf{m}$-algebra.)

[698] To make sense of this statement, we need to recall that $\Lambda \otimes \Lambda$ has been made into a functor of $\mathbf{k}$.

In Step 1, we have shown that Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Q}$. In other words, we have $\mathbf{v}_n \circ \mathbf{f}_n = \mathrm{id}_\Lambda^{\star n}$ if $\mathbf{k} = \mathbb{Q}$. In other words,

$$\mathbf{v}_n^{[\mathbb{Q}]} \circ \mathbf{f}_n^{[\mathbb{Q}]} = \mathrm{id}_{\Lambda_\mathbb{Q}}^{\star n}. \tag{13.87.41}$$

Recall that $\left(m_\lambda^{[\mathbf{k}]}\right)_{\lambda \in \mathrm{Par}} = (m_\lambda)_{\lambda \in \mathrm{Par}}$ is a basis of the $\mathbf{k}$-module $\Lambda_\mathbf{k}$ for every commutative ring $\mathbf{k}$. Applying this to $\mathbf{k} = \mathbb{Z}$, we conclude that $\left(m_\lambda^{[\mathbb{Z}]}\right)_{\lambda \in \mathrm{Par}}$ is a basis of the $\mathbb{Z}$-module $\Lambda_\mathbb{Z}$.

The ring homomorphism $\rho_\mathbb{Q} : \mathbb{Z} \to \mathbb{Q}$ is just the canonical inclusion of $\mathbb{Z}$ into $\mathbb{Q}$, and thus is injective. Hence, the map $\Lambda^{[\rho_\mathbb{Q}]}$ is injective (because $\Lambda^{[\varphi]}$ is injective for every injective ring homomorphism φ).

Now, let us recall that our goal (in Step 2) is to show that Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Z}$. In other words, our goal is to show that

$$\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]} = \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}.$$

This is an equality between $\mathbb{Z}$-module homomorphisms (indeed, it is clear that both $\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]}$ and $\mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}$ are $\mathbb{Z}$-module homomorphisms). Hence, in order to prove it, it is sufficient to verify it on the basis $\left(m_\lambda^{[\mathbb{Z}]}\right)_{\lambda \in \mathrm{Par}}$ of the $\mathbb{Z}$-module $\Lambda_\mathbb{Z}$. In other words, it is sufficient to prove that

$$\left(\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) = \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}\left(m_\lambda^{[\mathbb{Z}]}\right) \qquad \text{for every } \lambda \in \mathrm{Par}. \tag{13.87.42}$$

So let us prove (13.87.42) now:

Proof of (13.87.42): Let $\lambda \in \mathrm{Par}$. We have

$$\begin{aligned}
&\Lambda^{[\rho_\mathbb{Q}]}\left(\left(\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]}\right)\left(m_\lambda^{[\mathbb{Z}]}\right)\right) \\
&= \left(\underbrace{\Lambda^{[\rho_\mathbb{Q}]} \circ \mathbf{v}_n^{[\mathbb{Z}]}}_{\substack{= \mathbf{v}_n^{[\mathbb{Q}]} \circ \Lambda^{[\rho_\mathbb{Q}]} \\ \text{(because of } \mathbf{v}_n^{[\mathbb{Q}]} \circ \Lambda^{[\rho_\mathbb{Q}]} = \Lambda^{[\rho_\mathbb{Q}]} \circ \mathbf{v}_n^{[\mathbb{Z}]} \\ \text{(by (13.87.39), applied} \\ \text{to } \mathbf{m} = \mathbb{Z},\ \mathbf{n} = \mathbb{Q} \text{ and } \varphi = \rho_\mathbb{Q}))}} \circ \mathbf{f}_n^{[\mathbb{Z}]}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) = \left(\mathbf{v}_n^{[\mathbb{Q}]} \circ \underbrace{\Lambda^{[\rho_\mathbb{Q}]} \circ \mathbf{f}_n^{[\mathbb{Z}]}}_{\substack{= \mathbf{f}_n^{[\mathbb{Q}]} \circ \Lambda^{[\rho_\mathbb{Q}]} \\ \text{(because of } \mathbf{f}_n^{[\mathbb{Q}]} \circ \Lambda^{[\rho_\mathbb{Q}]} = \Lambda^{[\rho_\mathbb{Q}]} \circ \mathbf{f}_n^{[\mathbb{Z}]} \\ \text{(by (13.87.38), applied} \\ \text{to } \mathbf{m} = \mathbb{Z},\ \mathbf{n} = \mathbb{Q} \text{ and } \varphi = \rho_\mathbb{Q}))}}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) \\
&= \left(\underbrace{\mathbf{v}_n^{[\mathbb{Q}]} \circ \mathbf{f}_n^{[\mathbb{Q}]}}_{\substack{= \mathrm{id}_{\Lambda_\mathbb{Q}}^{\star n} \\ \text{(by (13.87.41))}}} \circ \Lambda^{[\rho_\mathbb{Q}]}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) = \underbrace{\left(\mathrm{id}_{\Lambda_\mathbb{Q}}^{\star n} \circ \Lambda^{[\rho_\mathbb{Q}]}\right)}_{\substack{= \Lambda^{[\rho_\mathbb{Q}]} \circ \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n} \\ \text{(by (13.87.40), applied} \\ \text{to } \mathbf{m} = \mathbb{Z},\ \mathbf{n} = \mathbb{Q} \text{ and } \varphi = \rho_\mathbb{Q})}} \left(m_\lambda^{[\mathbb{Z}]}\right) \\
&= \left(\Lambda^{[\rho_\mathbb{Q}]} \circ \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) = \Lambda^{[\rho_\mathbb{Q}]}\left(\mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}\left(m_\lambda^{[\mathbb{Z}]}\right)\right).
\end{aligned}$$

Since the map $\Lambda^{[\rho_\mathbb{Q}]}$ is injective, this yields $\left(\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) = \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}\left(m_\lambda^{[\mathbb{Z}]}\right)$. Thus, (13.87.42) is proven.

As we said, proving (13.87.42) is sufficient to showing that $\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]} = \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}$. Hence, $\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]} = \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}$ is shown (since (13.87.42) is proven). In other words, Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Z}$. This completes Step 2.

Step 3: We shall now prove that Exercise 2.9.10(g) holds in the general case.

Let us use all the notations that we introduced in Step 2.

In Step 2, we have shown that Exercise 2.9.10(g) holds if $\mathbf{k} = \mathbb{Z}$. In other words, we have $\mathbf{v}_n \circ \mathbf{f}_n = \mathrm{id}_\Lambda^{\star n}$ if $\mathbf{k} = \mathbb{Z}$. In other words,

$$\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]} = \mathrm{id}_{\Lambda_\mathbb{Z}}^{\star n}. \tag{13.87.43}$$

Recall that $(m_\lambda)_{\lambda \in \mathrm{Par}}$ is a basis of the $\mathbf{k}$-module $\Lambda_\mathbf{k}$.

Now, let us recall that our goal (in Step 3) is to show that Exercise 2.9.10(g) holds. In other words, our goal is to show that

$$\mathbf{v}_n \circ \mathbf{f}_n = \mathrm{id}^{\star n}.$$

This is an equality between $\mathbf{k}$-module homomorphisms (indeed, it is clear that both $\mathbf{v}_n \circ \mathbf{f}_n$ and $\operatorname{id}^{\star n}$ are $\mathbf{k}$-module homomorphisms). Hence, in order to prove it, it is sufficient to verify it on the basis $(m_\lambda)_{\lambda \in \operatorname{Par}}$ of the $\mathbf{k}$-module $\Lambda_{\mathbf{k}}$. In other words, it is sufficient to prove that

$$(\mathbf{v}_n \circ \mathbf{f}_n)(m_\lambda) = \operatorname{id}^{\star n}(m_\lambda) \qquad \text{for every } \lambda \in \operatorname{Par}. \tag{13.87.44}$$

So let us prove (13.87.44) now:

Proof of (13.87.44): Let $\lambda \in \operatorname{Par}$. Then,

$$m_\lambda = m_\lambda^{[\mathbf{k}]} = \Lambda^{[\rho_{\mathbf{k}}]}\left(m_\lambda^{[\mathbb{Z}]}\right) \qquad (\text{by (13.87.37) (applied to } \mathbf{m} = \mathbb{Z},\ \mathbf{n} = \mathbf{k} \text{ and } \varphi = \rho_{\mathbf{k}})). \tag{13.87.45}$$

Hence,

$$\left(\underbrace{\mathbf{v}_n}_{=\mathbf{v}_n^{[\mathbf{k}]}} \circ \underbrace{\mathbf{f}_n}_{=\mathbf{f}_n^{[\mathbf{k}]}}\right)\left(\underbrace{m_\lambda}_{=\Lambda^{[\rho_{\mathbf{k}}]}\left(m_\lambda^{[\mathbb{Z}]}\right)}\right) = \left(\mathbf{v}_n^{[\mathbf{k}]} \circ \mathbf{f}_n^{[\mathbf{k}]}\right)\left(\Lambda^{[\rho_{\mathbf{k}}]}\left(m_\lambda^{[\mathbb{Z}]}\right)\right) = \left(\mathbf{v}_n^{[\mathbf{k}]} \circ \underbrace{\mathbf{f}_n^{[\mathbf{k}]} \circ \Lambda^{[\rho_{\mathbf{k}}]}}_{\substack{=\Lambda^{[\rho_{\mathbf{k}}]} \circ \mathbf{f}_n^{[\mathbb{Z}]} \\ \text{(by (13.87.38), applied} \\ \text{to } \mathbf{m}=\mathbb{Z},\ \mathbf{n}=\mathbf{k} \text{ and } \varphi=\rho_{\mathbf{k}})}}\right)\left(m_\lambda^{[\mathbb{Z}]}\right)$$

$$= \left(\underbrace{\mathbf{v}_n^{[\mathbf{k}]} \circ \Lambda^{[\rho_{\mathbf{k}}]}}_{\substack{=\Lambda^{[\rho_{\mathbf{k}}]} \circ \mathbf{v}_n^{[\mathbb{Z}]} \\ \text{(by (13.87.39), applied} \\ \text{to } \mathbf{m}=\mathbb{Z},\ \mathbf{n}=\mathbf{k} \text{ and } \varphi=\rho_{\mathbf{k}})}} \circ \mathbf{f}_n^{[\mathbb{Z}]}\right)\left(m_\lambda^{[\mathbb{Z}]}\right)$$

$$= \left(\Lambda^{[\rho_{\mathbf{k}}]} \circ \underbrace{\mathbf{v}_n^{[\mathbb{Z}]} \circ \mathbf{f}_n^{[\mathbb{Z}]}}_{\substack{=\operatorname{id}_{\Lambda_{\mathbb{Z}}}^{\star n} \\ \text{(by (13.87.43))}}}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) = \underbrace{\left(\Lambda^{[\rho_{\mathbf{k}}]} \circ \operatorname{id}_{\Lambda_{\mathbb{Z}}}^{\star n}\right)}_{\substack{=\operatorname{id}_{\Lambda_{\mathbf{k}}}^{\star n} \circ \Lambda^{[\rho_{\mathbf{k}}]} \\ \text{(because of } \operatorname{id}_{\Lambda_{\mathbf{k}}}^{\star n} \circ \Lambda^{[\rho_{\mathbf{k}}]} = \Lambda^{[\rho_{\mathbf{k}}]} \circ \operatorname{id}_{\Lambda_{\mathbb{Z}}}^{\star n} \\ \text{(by (13.87.40), applied} \\ \text{to } \mathbf{m}=\mathbb{Z},\ \mathbf{n}=\mathbf{k} \text{ and } \varphi=\rho_{\mathbf{k}}))}}\left(m_\lambda^{[\mathbb{Z}]}\right)$$

$$= \left(\operatorname{id}_{\Lambda_{\mathbf{k}}}^{\star n} \circ \Lambda^{[\rho_{\mathbf{k}}]}\right)\left(m_\lambda^{[\mathbb{Z}]}\right) = \underbrace{\operatorname{id}_{\Lambda_{\mathbf{k}}}^{\star n}}_{=\operatorname{id}^{\star n}}\left(\underbrace{\Lambda^{[\rho_{\mathbf{k}}]}\left(m_\lambda^{[\mathbb{Z}]}\right)}_{\substack{=m_\lambda \\ \text{(by (13.87.45))}}}\right) = \operatorname{id}^{\star n}(m_\lambda).$$

Thus, (13.87.44) is proven.

As we said, proving (13.87.44) is sufficient to showing that $\mathbf{v}_n \circ \mathbf{f}_n = \operatorname{id}^{\star n}$. Hence, $\mathbf{v}_n \circ \mathbf{f}_n = \operatorname{id}^{\star n}$ is shown (since (13.87.44) is proven). In other words, Exercise 2.9.10(g) holds in the general case. This completes Step 3 and, with it, the solution of Exercise 2.9.10(g).

(h) The structure of our solution of Exercise 2.9.10(h) is similar to that of our solution of Exercise 2.9.10(g) above. It proceeds in three steps:

- *Step 1:* proving that Exercise 2.9.10(h) holds if $\mathbf{k} = \mathbb{Q}$.
- *Step 2:* proving that Exercise 2.9.10(h) holds if $\mathbf{k} = \mathbb{Z}$.
- *Step 3:* proving that Exercise 2.9.10(h) holds in the general case.

The details of Steps 2 and 3 are very similar to the details of the corresponding steps in the solution of Exercise 2.9.10(g), and so we will not dwell on these details. However, we need to give the details of Step 1:

Step 1: We shall prove that Exercise 2.9.10(h) holds if $\mathbf{k} = \mathbb{Q}$.

Indeed, assume that $\mathbf{k} = \mathbb{Q}$. We know that $\mathbf{f}_n$ is a $\mathbf{k}$-algebra homomorphism (due to Exercise 2.9.9(a)), and that $\mathbf{v}_m$ is a $\mathbf{k}$-algebra homomorphism. Hence, $\mathbf{f}_n \circ \mathbf{v}_m$ and $\mathbf{v}_m \circ \mathbf{f}_n$ are $\mathbf{k}$-algebra homomorphisms.

Let r be a positive integer. We shall show that $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = (\mathbf{v}_m \circ \mathbf{f}_n)(p_r)$.

Indeed, we first notice that

$$\mathbf{f}_n(p_r) = p_{rn}. \tag{13.87.46}$$

(This can be proven just as in (13.87.35).)

Now, let us first assume that $m \nmid r$. Then, Exercise 2.9.10(a) (applied to m and r instead of n and m) yields

$$\mathbf{v}_m(p_r) = \begin{cases} mp_{r/m}, & \text{if } m \mid r; \\ 0, & \text{if } m \nmid r \end{cases} = 0 \qquad (\text{since } m \nmid r),$$

so that $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = \mathbf{f}_n\left(\underbrace{\mathbf{v}_m(p_r)}_{=0}\right) = \mathbf{f}_n(0) = 0$ (since the map $\mathbf{f}_n$ is $\mathbf{k}$-linear). On the other hand, if we had $m \mid rn$, then we would have $m \mid r$ (since m is coprime to n), which would contradict $m \nmid r$. Hence, we cannot have $m \mid rn$. Thus, we have $m \nmid rn$. Now,

$$\begin{aligned}(\mathbf{v}_m \circ \mathbf{f}_n)(p_r) &= \mathbf{v}_m\left(\underbrace{\mathbf{f}_n(p_r)}_{\substack{=p_{rn} \\ (\text{by } (13.87.46))}}\right) = \mathbf{v}_m(p_{rn}) = \begin{cases} mp_{rn/m}, & \text{if } m \mid rn; \\ 0, & \text{if } m \nmid rn \end{cases} \\ &\qquad (\text{by Exercise 2.9.10(a), applied to } m \text{ and } rn \text{ instead of } n \text{ and } m) \\ &= 0 \qquad (\text{since } m \nmid rn).\end{aligned}$$

Compared with $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = 0$, this yields $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = (\mathbf{v}_m \circ \mathbf{f}_n)(p_r)$.

Now, let us forget our assumption that $m \nmid r$. Hence, we have proven that $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = (\mathbf{v}_m \circ \mathbf{f}_n)(p_r)$ under the assumption that $m \nmid r$. As a consequence, for the rest of the proof of $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = (\mathbf{v}_m \circ \mathbf{f}_n)(p_r)$, we can WLOG assume that we don't have $m \nmid r$. Assume this.

We have $m \mid r$ (since we don't have $m \nmid r$). Now, Exercise 2.9.10(a) (applied to m and r instead of n and m) yields

$$\mathbf{v}_m(p_r) = \begin{cases} mp_{r/m}, & \text{if } m \mid r; \\ 0, & \text{if } m \nmid r \end{cases} = mp_{r/m} \qquad (\text{since } m \mid r),$$

so that

$$\begin{aligned}(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) &= \mathbf{f}_n\left(\underbrace{\mathbf{v}_m(pr)}_{=mp_{r/m}}\right) = \mathbf{f}_n\left(mp_{r/m}\right) = m \underbrace{\mathbf{f}_n\left(p_{r/m}\right)}_{\substack{=p_{(r/m)n} \\ (\text{by } (13.87.46), \text{ applied to} \\ r/m \text{ instead of } r)}} \qquad (\text{since the map } \mathbf{f}_n \text{ is } \mathbf{k}\text{-linear}) \\ &= mp_{(r/m)n} = mp_{rn/m} \qquad (\text{since } (r/m)\,n = rn/m).\end{aligned}$$

Compared with

$$\begin{aligned}(\mathbf{v}_m \circ \mathbf{f}_n)(p_r) &= \mathbf{v}_m\left(\underbrace{\mathbf{f}_n(p_r)}_{\substack{=p_{rn} \\ (\text{by } (13.87.46))}}\right) = \mathbf{v}_m(p_{rn}) = \begin{cases} mp_{rn/m}, & \text{if } m \mid rn; \\ 0, & \text{if } m \nmid rn \end{cases} \\ &\qquad (\text{by Exercise 2.9.10(a), applied to } m \text{ and } rn \text{ instead of } n \text{ and } m) \\ &= mp_{rn/m} \qquad (\text{since } m \mid rn \text{ (since } m \mid r \mid rn)),\end{aligned}$$

this yields $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = (\mathbf{v}_m \circ \mathbf{f}_n)(p_r)$. Hence, $(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = (\mathbf{v}_m \circ \mathbf{f}_n)(p_r)$ is proven.

Now, let us forget that we fixed r. We thus have proven that

$$(\mathbf{f}_n \circ \mathbf{v}_m)(p_r) = (\mathbf{v}_m \circ \mathbf{f}_n)(p_r) \qquad \text{for every positive integer } r. \tag{13.87.47}$$

We have assumed that $\mathbf{k} = \mathbb{Q}$. Thus, $\mathbb{Q}$ is a subring of $\mathbf{k}$. Hence, the elements $p_1, p_2, p_3, \ldots$ of Λ generate the $\mathbf{k}$-algebra Λ (due to Proposition 2.4.1). But $\mathbf{f}_n \circ \mathbf{v}_m$ and $\mathbf{v}_m \circ \mathbf{f}_n$ are two $\mathbf{k}$-algebra homomorphisms from Λ. These two homomorphisms $\mathbf{f}_n \circ \mathbf{v}_m$ and $\mathbf{v}_m \circ \mathbf{f}_n$ are equal to each other on each of the elements $p_1, p_2, p_3, \ldots$ (due to (13.87.47)), and therefore are identical (because if two $\mathbf{k}$-algebra homomorphisms with one and the same domain are equal to each other on a generating set of the domain, then these homomorphisms must be identical). In other words, $\mathbf{f}_n \circ \mathbf{v}_m = \mathbf{v}_m \circ \mathbf{f}_n$. Thus, Exercise 2.9.10(h) is solved under the assumption that $\mathbf{k} = \mathbb{Q}$. Our Step 1 is complete.

As already mentioned, Steps 2 and Steps 3 are very similar to the corresponding steps in our above solution of Exercise 2.9.10(g). Thus, we forego showing these steps. Exercise 2.9.10(h) is thus solved.

(i) Our solution of Exercise 2.9.10(i) will be somewhat similar to that of Exercise 2.9.10(g), but simpler. We will only need two steps:

- *Step 1:* proving that Exercise 2.9.10(i) holds if $\mathbf{k} = \mathbb{Z}$.
- *Step 2:* proving that Exercise 2.9.10(i) holds in the general case.

Let us go through the details of each step:

Step 1: We shall prove that Exercise 2.9.10(i) holds if $\mathbf{k} = \mathbb{Z}$.

Indeed, assume that $\mathbf{k} = \mathbb{Z}$. Every positive integer r satisfies

$$p_r = \sum_{d \mid r} d w_d^{r/d} \tag{13.87.48}$$

(according to Exercise 2.9.3(e), applied to r instead of n).

Now, for every positive integer m, we define an element $\widetilde{w}_m$ of Λ by

$$\widetilde{w}_m = \begin{cases} w_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} . \tag{13.87.49}$$

It is now easy to see that every positive integer r satisfies

$$\mathbf{v}_n \left(p_r\right) = \sum_{d \mid r} d \widetilde{w}_d^{r/d}. \tag{13.87.50}$$

[699]

We shall now prove that every positive integer m satisfies

$$\mathbf{v}_n \left(w_m\right) = \widetilde{w}_m. \tag{13.87.52}$$

[699] *Proof of (13.87.50):* Let r be a positive integer. Let us first assume that $n \nmid r$. Then, every positive divisor d of r satisfies

$$\begin{aligned} \widetilde{w}_d &= \begin{cases} w_{d/n}, & \text{if } n \mid d; \\ 0, & \text{if } n \nmid d \end{cases} \qquad \left(\text{by the definition of } \widetilde{w}_d\right) \\ &= 0 \qquad \left(\begin{array}{c} \text{since } n \nmid d \text{ (because otherwise, we would have } n \mid d \\ \text{and thus } n \mid d \mid r \text{, which would contradict } n \nmid r) \end{array}\right). \end{aligned} \tag{13.87.51}$$

But Exercise 2.9.10(a) (applied to r instead of m) yields

$$\mathbf{v}_n \left(p_r\right) = \begin{cases} n p_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases} = 0 \qquad \left(\text{since } n \nmid r\right).$$

Compared with

$$\sum_{d \mid r} d \widetilde{w}_d^{r/d} = \sum_{d \mid r} d \left(\underbrace{\widetilde{w}_d}_{\substack{=0 \\ \text{(by (13.87.51))}}} \right)^{r/d} = \sum_{d \mid r} d \underbrace{0^{r/d}}_{\substack{=0 \\ \text{(since } r/d>0)}} = \sum_{d \mid r} d 0 = 0,$$

this yields $\mathbf{v}_n \left(p_r\right) = \sum_{d \mid r} d \widetilde{w}_d^{r/d}$. Thus, (13.87.50) holds.

Let us now forget that we assumed that $n \nmid r$. We thus have proven (13.87.50) under the assumption that $n \nmid r$. Hence, for the rest of the proof of (13.87.50), we can WLOG assume that we don't have $n \nmid r$. Assume this.

We have $n \mid r$ (since we don't have $n \nmid r$). Hence, r/n is a positive integer. Exercise 2.9.10(a) (applied to r instead of m) yields

$$\begin{aligned} \mathbf{v}_n \left(p_r\right) &= \begin{cases} n p_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases} = n \underbrace{p_{r/n}}_{\substack{=\sum_{d \mid r/n} d w_d^{(r/n)/d} \\ \text{(by (13.87.48), applied to} \\ r/n \text{ instead of } r)}} \qquad \left(\text{since } n \mid r\right) \\ &= n \sum_{d \mid r/n} d w_d^{(r/n)/d} = \sum_{d \mid r/n} n d \underbrace{w_d^{(r/n)/d}}_{\substack{=w_d^{r/(nd)} \\ \text{(since } (r/n)/d = r/(nd))}} = \sum_{d \mid r/n} n d w_d^{r/(nd)}. \end{aligned}$$

Proof of (13.87.52): We proceed by strong induction over m:

Induction step: Fix a positive integer M. Assume that (13.87.52) holds for every positive integer $m < M$. We now must show that (13.87.52) holds for $m = M$.

The $\mathbf{k}$-module Λ is free, and thus torsionfree. Hence,

$$\text{every element } a \text{ of } \Lambda \text{ satisfying } Ma = 0 \text{ satisfies } a = 0 \tag{13.87.53}$$

(since $\mathbf{k} = \mathbb{Z}$).

We have assumed that (13.87.52) holds for every positive integer $m < M$. In other words,

$$\mathbf{v}_n \left(w_m \right) = \widetilde{w}_m \qquad \text{for every positive integer } m < M. \tag{13.87.54}$$

Compared with

$$\begin{aligned}
\sum_{d|r} d\widetilde{w}_d^{r/d} &= \sum_{d|r} d \left(\underbrace{\widetilde{w}_d}_{\substack{= \begin{cases} w_{d/n}, & \text{if } n \mid d; \\ 0, & \text{if } n \nmid d \end{cases} \\ \text{(by the definition of } \widetilde{w}_d)}} \right)^{r/d} = \sum_{d|r} d \left(\begin{cases} w_{d/n}, & \text{if } n \mid d; \\ 0, & \text{if } n \nmid d \end{cases} \right)^{r/d} \\
&= \sum_{\substack{d|r; \\ n|d}} d \left(\underbrace{\begin{cases} w_{d/n}, & \text{if } n \mid d; \\ 0, & \text{if } n \nmid d \end{cases}}_{\substack{= w_{d/n} \\ \text{(since } n|d)}} \right)^{r/d} + \sum_{\substack{d|r; \\ n\nmid d}} d \left(\underbrace{\begin{cases} w_{d/n}, & \text{if } n \mid d; \\ 0, & \text{if } n \nmid d \end{cases}}_{\substack{=0 \\ \text{(since } n\nmid d)}} \right)^{r/d} \\
&= \sum_{\substack{d|r; \\ n|d}} dw_{d/n}^{r/d} + \sum_{\substack{d|r; \\ n\nmid d}} d \underbrace{0^{r/d}}_{\substack{=0 \\ \text{(since } r/d>0)}} = \sum_{\substack{d|r; \\ n|d}} dw_{d/n}^{r/d} + \underbrace{\sum_{\substack{d|r; \\ n\nmid d}} d0}_{=0} = \sum_{\substack{d|r; \\ n|d}} dw_{d/n}^{r/d} \\
&= \sum_{d|r/n} nd \underbrace{w_{nd/n}^{r/(nd)}}_{\substack{= w_d^{r/(nd)} \\ \text{(since } nd/n=d)}} \qquad \text{(here, we have substituted } nd \text{ for } d \text{ in the sum)} \\
&= \sum_{d|r/n} ndw_d^{r/(nd)},
\end{aligned}$$

this yields $\mathbf{v}_n \left(p_r \right) = \sum_{d|r} d\widetilde{w}_d^{r/d}$. Thus, (13.87.50) is proven.

Applying (13.87.48) to $r = M$, we obtain $p_M = \sum_{d|M} d w_d^{M/d}$. Applying the map $\mathbf{v}_n$ to both sides of this equality, we obtain

$$\begin{aligned}
\mathbf{v}_n(p_M) &= \mathbf{v}_n\left(\sum_{d|M} d w_d^{M/d}\right) = \sum_{d|M} d\left(\mathbf{v}_n(w_d)\right)^{M/d} \qquad (\text{since } \mathbf{v}_n \text{ is a } \mathbf{k}\text{-algebra homomorphism}) \\
&= M \underbrace{\left(\mathbf{v}_n(w_M)\right)^{M/M}}_{=(\mathbf{v}_n(w_M))^1=\mathbf{v}_n(w_M)} + \underbrace{\sum_{\substack{d|M;\\ d\neq M}}}_{=\sum_{\substack{d|M;\\ d<M}}} d\left(\mathbf{v}_n(w_d)\right)^{M/d} \\
&\qquad (\text{here, we have split off the addend for } d = M \text{ from the sum}) \\
&= M\mathbf{v}_n(w_M) + \sum_{\substack{d|M;\\ d<M}} d\left(\underbrace{\mathbf{v}_n(w_d)}_{\substack{=\widetilde{w}_d \\ (\text{by (13.87.54), applied} \\ \text{to } m=d)}}\right)^{M/d} = M\mathbf{v}_n(w_M) + \sum_{\substack{d|M;\\ d<M}} d\widetilde{w}_d^{M/d}.
\end{aligned}$$

Compared with

$$\begin{aligned}
\mathbf{v}_n(p_M) &= \sum_{d|M} d\widetilde{w}_d^{M/d} \qquad (\text{by (13.87.50), applied to } r = M) \\
&= M \underbrace{\widetilde{w}_M^{M/M}}_{=\widetilde{w}_M^1=\widetilde{w}_M} + \underbrace{\sum_{\substack{d|M;\\ d\neq M}}}_{=\sum_{\substack{d|M;\\ d<M}}} d\widetilde{w}_d^{M/d} \qquad (\text{here, we have split off the addend for } d = M \text{ from the sum}) \\
&= M\widetilde{w}_M + \sum_{\substack{d|M;\\ d<M}} d\widetilde{w}_d^{M/d},
\end{aligned}$$

this yields

$$M\mathbf{v}_n(w_M) + \sum_{\substack{d|M;\\ d<M}} d\widetilde{w}_d^{M/d} = M\widetilde{w}_M + \sum_{\substack{d|M;\\ d<M}} d\widetilde{w}_d^{M/d}.$$

Subtracting $\sum_{\substack{d|M;\\ d<M}} d\widetilde{w}_d^{M/d}$ from both sides of this equality, we obtain $M\mathbf{v}_n(w_M) = M\widetilde{w}_M$. Hence,

$$M\left(\mathbf{v}_n(w_M) - \widetilde{w}_M\right) = \underbrace{M\mathbf{v}_n(w_M)}_{=M\widetilde{w}_M} - M\widetilde{w}_M = M\widetilde{w}_M - M\widetilde{w}_M = 0.$$

Thus, (13.87.53) (applied to $a = \mathbf{v}_n(w_M) - \widetilde{w}_M$) yields $\mathbf{v}_n(w_M) - \widetilde{w}_M = 0$, so that $\mathbf{v}_n(w_M) = \widetilde{w}_M$. In other words, (13.87.52) holds for $m = M$. This completes the induction step. Thus, (13.87.52) is proven.

Now, every positive integer m satisfies

$$\begin{aligned}
\mathbf{v}_n(w_m) &= \widetilde{w}_m \qquad (\text{by (13.87.52)}) \\
&= \begin{cases} w_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} \qquad (\text{by the definition of } \widetilde{w}_m).
\end{aligned}$$

Thus, Exercise 2.9.10(i) is solved in the case when $\mathbf{k} = \mathbb{Z}$. In other words, Step 1 is finished.

Step 2: We shall now show that Exercise 2.9.10(i) holds in the general case.

Indeed, let us use all the notations that we introduced in Step 2 of the solution of Exercise 2.9.10(g). Let us furthermore introduce one more notation:

- For every positive integer m, we shall denote the element w_m of Λ by $w_m^{[\mathbf{k}]}$. This notation makes the dependency of w_m on the base ring $\mathbf{k}$ more explicit. Of course, the element w_m does not "really" depend on $\mathbf{k}$, in the sense that it is defined in the same way for every $\mathbf{k}$. This entails that for any two commutative rings $\mathbf{m}$ and $\mathbf{n}$ and any ring homomorphism $\varphi : \mathbf{m} \to \mathbf{n}$, we have
$$w_m^{[\mathbf{n}]} = \Lambda^{[\varphi]} \left(w_m^{[\mathbf{m}]} \right) \tag{13.87.55}$$
for every positive integer m.

Now, fix a positive integer m. In Step 1, we have shown that Exercise 2.9.10(i) holds if $\mathbf{k} = \mathbb{Z}$. In other words, we have
$$\mathbf{v}_n \left(w_m \right) = \begin{cases} w_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} \qquad \text{if } \mathbf{k} = \mathbb{Z}.$$
In other words,
$$\mathbf{v}_n^{[\mathbb{Z}]} \left(w_m^{[\mathbb{Z}]} \right) = \begin{cases} w_{m/n}^{[\mathbb{Z}]}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} . \tag{13.87.56}$$

Now,
$$w_m = w_m^{[\mathbf{k}]} = \Lambda^{[\rho_{\mathbf{k}}]} \left(w_m^{[\mathbb{Z}]} \right) \tag{13.87.57}$$
(by (13.87.55) (applied to $\mathbf{m} = \mathbb{Z}$, $\mathbf{n} = \mathbf{k}$ and $\varphi = \rho_{\mathbf{k}}$)). Thus,
$$\begin{aligned}
\underbrace{\mathbf{v}_n}_{=\mathbf{v}_n^{[\mathbf{k}]}} \left(\underbrace{w_m}_{=\Lambda^{[\rho_{\mathbf{k}}]}\left(w_m^{[\mathbb{Z}]}\right)} \right) &= \mathbf{v}_n^{[\mathbf{k}]} \left(\Lambda^{[\rho_{\mathbf{k}}]} \left(w_m^{[\mathbb{Z}]} \right) \right) = \underbrace{\left(\mathbf{v}_n^{[\mathbf{k}]} \circ \Lambda^{[\rho_{\mathbf{k}}]} \right)}_{\substack{=\Lambda^{[\rho_{\mathbf{k}}]} \circ \mathbf{v}_n^{[\mathbb{Z}]} \\ \text{(by (13.87.39), applied to} \\ \mathbf{m}=\mathbb{Z},\ \mathbf{n}=\mathbf{k} \text{ and } \varphi=\rho_{\mathbf{k}})}} \left(w_m^{[\mathbb{Z}]} \right) \\
&= \left(\Lambda^{[\rho_{\mathbf{k}}]} \circ \mathbf{v}_n^{[\mathbb{Z}]} \right) \left(w_m^{[\mathbb{Z}]} \right) = \Lambda^{[\rho_{\mathbf{k}}]} \left(\underbrace{\mathbf{v}_n^{[\mathbb{Z}]} \left(w_m^{[\mathbb{Z}]} \right)}_{\substack{= \begin{cases} w_{m/n}^{[\mathbb{Z}]}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} \\ \text{(by (13.87.56))}}} \right) \\
&= \Lambda^{[\rho_{\mathbf{k}}]} \left(\begin{cases} w_{m/n}^{[\mathbb{Z}]}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} \right) = \begin{cases} \Lambda^{[\rho_{\mathbf{k}}]} \left(w_{m/n}^{[\mathbb{Z}]} \right), & \text{if } n \mid m; \\ \Lambda^{[\rho_{\mathbf{k}}]} \left(0 \right), & \text{if } n \nmid m \end{cases} \\
&= \begin{cases} \Lambda^{[\rho_{\mathbf{k}}]} \left(w_{m/n}^{[\mathbb{Z}]} \right), & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} \\
&\qquad \left(\begin{array}{c} \text{since } \Lambda^{[\rho_{\mathbf{k}}]} \left(0 \right) = 0 \text{ (because } \Lambda^{[\rho_{\mathbf{k}}]} \text{ is a ring homomorphism)} \\ \text{in the case when } n \nmid m \end{array} \right) .
\end{aligned} \tag{13.87.58}$$

On the other hand, we have
$$\Lambda^{[\rho_{\mathbf{k}}]} \left(w_{m/n}^{[\mathbb{Z}]} \right) = w_{m/n} \qquad \text{in the case when } n \mid m \tag{13.87.59}$$

[700]. Now, (13.87.58) becomes

$$\mathbf{v}_n (w_m) = \begin{cases} \Lambda^{[\rho_{\mathbf{k}}]} \left(w^{[\mathbb{Z}]}_{m/n} \right), & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases} = \begin{cases} w_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m \end{cases}$$

$$\left(\begin{array}{c} \text{since } \Lambda^{[\rho_{\mathbf{k}}]} \left(w^{[\mathbb{Z}]}_{m/n} \right) = w_{m/n} \text{ (according to (13.87.59))} \\ \text{in the case when } n \mid m \end{array} \right).$$

Thus, Exercise 2.9.10(i) holds. This completes Step 2, and thus Exercise 2.9.10(i) is solved.

13.88. **Solution to Exercise 2.9.11.** *Solution to Exercise 2.9.11.* (b) Let us first notice that

$$X_{n,d,s} = \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n; \\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s}} x_{w_1} x_{w_2} \cdots x_{w_n} \qquad \text{for all } d \in \mathbb{N} \text{ and } s \in \mathbb{N}. \tag{13.88.1}$$

(This is just the definition of $X_{n,d,s}$, written as a formula.)

Let us first show that if n is a positive integer, then any $d \in \mathbb{N}$ and $s \in \mathbb{N}$ satisfy

$$\begin{aligned} &(d+1) X_{n,d+1,s} + (s+1) X_{n,d,s+1} + (n-1-d-s) X_{n,d,s} \\ &= \sum_{i=1}^{n-1} \sum_{e=0}^{d} \sum_{t=0}^{s} X_{i,e,t} X_{n-i,d-e,s-t}. \end{aligned} \tag{13.88.2}$$

Proof of (13.88.2): Let n be a positive integer. Let $d \in \mathbb{N}$ and $s \in \mathbb{N}$. Let $i \in \{1, 2, ..., n-1\}$ be arbitrary. We make some more definitions:

- Define a power series $\mathcal{D}_i \in \mathbf{k}[[\mathbf{x}]]$ as the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all n-tuples $w = (w_1, w_2, ..., w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d+1$, $|\operatorname{Stag}(w)| = s$ and $w_i > w_{i+1}$.
- Define a power series $\mathcal{S}_i \in \mathbf{k}[[\mathbf{x}]]$ as the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all n-tuples $w = (w_1, w_2, ..., w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d$, $|\operatorname{Stag}(w)| = s+1$ and $w_i = w_{i+1}$.
- Define a power series $\mathcal{A}_i \in \mathbf{k}[[\mathbf{x}]]$ as the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all n-tuples $w = (w_1, w_2, ..., w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d$, $|\operatorname{Stag}(w)| = s$ and $w_i < w_{i+1}$.

These three power series $\mathcal{D}_i$, $\mathcal{S}_i$ and $\mathcal{A}_i$ are not necessarily symmetric (but will nevertheless come useful). Let us notice that the definitions of $\mathcal{D}_i$, $\mathcal{S}_i$ and $\mathcal{A}_i$ can be rewritten as follows:

- The power series $\mathcal{D}_i \in \mathbf{k}[[\mathbf{x}]]$ is the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all n-tuples $w = (w_1, w_2, ..., w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $|(\operatorname{Des}(w)) \setminus \{i\}| = d$, $|(\operatorname{Stag}(w)) \setminus \{i\}| = s$ and $w_i > w_{i+1}$.
- The power series $\mathcal{S}_i \in \mathbf{k}[[\mathbf{x}]]$ is the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all n-tuples $w = (w_1, w_2, ..., w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $|(\operatorname{Des}(w)) \setminus \{i\}| = d$, $|(\operatorname{Stag}(w)) \setminus \{i\}| = s$ and $w_i = w_{i+1}$.
- The power series $\mathcal{A}_i \in \mathbf{k}[[\mathbf{x}]]$ is the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all n-tuples $w = (w_1, w_2, ..., w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $|(\operatorname{Des}(w)) \setminus \{i\}| = d$, $|(\operatorname{Stag}(w)) \setminus \{i\}| = s$ and $w_i < w_{i+1}$.

These reformulations make it obvious that the sum $\mathcal{D}_i + \mathcal{S}_i + \mathcal{A}_i$ is precisely the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all n-tuples $w = (w_1, w_2, ..., w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $|(\operatorname{Des}(w)) \setminus \{i\}| = d$ and $|(\operatorname{Stag}(w)) \setminus \{i\}| = s$. In other words,

$$\mathcal{D}_i + \mathcal{S}_i + \mathcal{A}_i = \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n; \\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s}} x_{w_1} x_{w_2} \cdots x_{w_n}. \tag{13.88.3}$$

But the sum on the right hand side of (13.88.3) can be rewritten in terms of more familiar sums. In fact, the n-tuples $w \in \{1, 2, 3, \ldots\}^n$ are in bijection with the pairs (u, v) consisting of an i-tuple $u \in \{1, 2, 3, \ldots\}^i$ and an $(n-i)$-tuple $v \in \{1, 2, 3, \ldots\}^{n-i}$. This bijection sends an n-tuple $(w_1, w_2, ..., w_n)$ to the

[700] *Proof of (13.87.59):* Assume that $n \mid m$. Then, m/n is a positive integer. Hence, $w_{m/n} = \Lambda^{[\rho_{\mathbf{k}}]} \left(w^{[\mathbb{Z}]}_{m/n} \right)$ (in fact, this follows from the same argument that was used to prove (13.87.57), but with m replaced by m/n). In other words, $\Lambda^{[\rho_{\mathbf{k}}]} \left(w^{[\mathbb{Z}]}_{m/n} \right) = w_{m/n}$. This proves (13.87.59).

pair $((w_1, w_2, ..., w_i), (w_{i+1}, w_{i+2}, ..., w_n))$, and has the property that $|(\operatorname{Des}(w)) \setminus \{i\}| = |\operatorname{Des}(u)| + |\operatorname{Des}(v)|$ [701] and $|(\operatorname{Stag}(w)) \setminus \{i\}| = |\operatorname{Stag}(u)| + |\operatorname{Stag}(v)|$ [702]. Hence,

$$\begin{aligned}
&\sum_{\substack{w=(w_1,w_2,...,w_n)\in\{1,2,3,...\}^n;\\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&= \underbrace{\sum_{\substack{u=(u_1,u_2,...,u_i)\in\{1,2,3,...\}^i;\\ v=(v_1,v_2,...,v_{n-i})\in\{1,2,3,...\}^{n-i};\\ |\operatorname{Des}(u)|+|\operatorname{Des}(v)|=d;\\ |\operatorname{Stag}(u)|+|\operatorname{Stag}(v)|=s}}}_{=\sum_{e=0}^{d}\sum_{t=0}^{s}\sum_{\substack{u=(u_1,u_2,...,u_i)\in\{1,2,3,...\}^i;\\ |\operatorname{Des}(u)|=e;\ |\operatorname{Stag}(u)|=t}}\sum_{\substack{v=(v_1,v_2,...,v_{n-i})\in\{1,2,3,...\}^{n-i};\\ |\operatorname{Des}(v)|=d-e;\ |\operatorname{Stag}(v)|=s-t}}} x_{u_1}x_{u_2}\cdots x_{u_i}x_{v_1}x_{v_2}\cdots x_{v_{n-i}} \\
&= \sum_{e=0}^{d}\sum_{t=0}^{s} \sum_{\substack{u=(u_1,u_2,...,u_i)\in\{1,2,3,...\}^i;\\ |\operatorname{Des}(u)|=e;\ |\operatorname{Stag}(u)|=t}} \sum_{\substack{v=(v_1,v_2,...,v_{n-i})\in\{1,2,3,...\}^{n-i};\\ |\operatorname{Des}(v)|=d-e;\ |\operatorname{Stag}(v)|=s-t}} x_{u_1}x_{u_2}\cdots x_{u_i}x_{v_1}x_{v_2}\cdots x_{v_{n-i}} \\
&= \sum_{e=0}^{d}\sum_{t=0}^{s} \left(\sum_{\substack{u=(u_1,u_2,...,u_i)\in\{1,2,3,...\}^i;\\ |\operatorname{Des}(u)|=e;\ |\operatorname{Stag}(u)|=t}} x_{u_1}x_{u_2}\cdots x_{u_i} \right) \left(\sum_{\substack{v=(v_1,v_2,...,v_{n-i})\in\{1,2,3,...\}^{n-i};\\ |\operatorname{Des}(v)|=d-e;\ |\operatorname{Stag}(v)|=s-t}} x_{v_1}x_{v_2}\cdots x_{v_{n-i}} \right). \qquad (13.88.4)
\end{aligned}$$

However, for every $e \in \{0, 1, ..., d\}$ and $t \in \{0, 1, ..., s\}$, the equality (13.88.1) (applied to i, e and t instead of n, d and s) yields

$$X_{i,e,t} = \sum_{\substack{w=(w_1,w_2,...,w_i)\in\{1,2,3,...\}^i;\\ |\operatorname{Des}(w)|=e;\ |\operatorname{Stag}(w)|=t}} x_{w_1}x_{w_2}\cdots x_{w_i} = \sum_{\substack{u=(u_1,u_2,...,u_i)\in\{1,2,3,...\}^i;\\ |\operatorname{Des}(u)|=e;\ |\operatorname{Stag}(u)|=t}} x_{u_1}x_{u_2}\cdots x_{u_i}. \tag{13.88.5}$$

Also, for every $e \in \{0, 1, ..., d\}$ and $t \in \{0, 1, ..., s\}$, the equality (13.88.1) (applied to $n - i$, $d - e$ and $s - t$ instead of n, d and s) yields

$$X_{n-i,d-e,s-t} = \sum_{\substack{w=(w_1,w_2,...,w_{n-i})\in\{1,2,3,...\}^{n-i};\\ |\operatorname{Des}(w)|=d-e;\ |\operatorname{Stag}(w)|=s-t}} x_{w_1}x_{w_2}\cdots x_{w_{n-i}} = \sum_{\substack{v=(v_1,v_2,...,v_{n-i})\in\{1,2,3,...\}^{n-i};\\ |\operatorname{Des}(v)|=d-e;\ |\operatorname{Stag}(v)|=s-t}} x_{v_1}x_{v_2}\cdots x_{v_{n-i}}. \tag{13.88.6}$$

Now, (13.88.4) becomes

$$\begin{aligned}
&\sum_{\substack{w=(w_1,w_2,...,w_n)\in\{1,2,3,...\}^n;\\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&= \sum_{e=0}^{d}\sum_{t=0}^{s} \underbrace{\left(\sum_{\substack{u=(u_1,u_2,...,u_i)\in\{1,2,3,...\}^i;\\ |\operatorname{Des}(u)|=e;\ |\operatorname{Stag}(u)|=t}} x_{u_1}x_{u_2}\cdots x_{u_i} \right)}_{\substack{=X_{i,e,t}\\ \text{(by (13.88.5))}}} \underbrace{\left(\sum_{\substack{v=(v_1,v_2,...,v_{n-i})\in\{1,2,3,...\}^{n-i};\\ |\operatorname{Des}(v)|=d-e;\ |\operatorname{Stag}(v)|=s-t}} x_{v_1}x_{v_2}\cdots x_{v_{n-i}} \right)}_{\substack{=X_{n-i,d-e,s-t}\\ \text{(by (13.88.6))}}} \\
&= \sum_{e=0}^{d}\sum_{t=0}^{s} X_{i,e,t}X_{n-i,d-e,s-t}.
\end{aligned}$$

[701] In fact, $(\operatorname{Des}(w))\setminus\{i\}$ is the union of the set $\operatorname{Des}(u)$ with the set $\operatorname{Des}(v)$ shifted by i (that is, the set $\{p + i \mid p \in \operatorname{Des}(v)\}$). This is a disjoint union, and thus we find $|(\operatorname{Des}(w)) \setminus \{i\}| = |\operatorname{Des}(u)| + |\operatorname{Des}(v)|$ (since the set $\operatorname{Des}(v)$ shifted by i has cardinality $|\operatorname{Des}(v)|$).

[702] for similar reasons

Hence, (13.88.3) becomes

$$\mathcal{D}_i + \mathcal{S}_i + \mathcal{A}_i = \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s}} x_{w_1}x_{w_2}\cdots x_{w_n}$$

$$= \sum_{e=0}^{d}\sum_{t=0}^{s} X_{i,e,t}X_{n-i,d-e,s-t}. \qquad (13.88.7)$$

Now, let us forget that we fixed i. We thus have defined $\mathcal{D}_i$, $\mathcal{S}_i$ and $\mathcal{A}_i$ and proven the equality (13.88.7) for all $i \in \{1, 2, ..., n-1\}$.

Now, let us take a closer look at the sums $\sum_{i=1}^{n-1}\mathcal{D}_i$, $\sum_{i=1}^{n-1}\mathcal{S}_i$ and $\sum_{i=1}^{n-1}\mathcal{A}_i$:

- The definition of $\mathcal{D}_i$ can be rewritten as follows:

$$\mathcal{D}_i = \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d+1;\ |\operatorname{Stag}(w)|=s;\ w_i>w_{i+1}}} x_{w_1}x_{w_2}\cdots x_{w_n} \qquad \text{for every } i\in\{1,2,...,n-1\}.$$

Summing up these equations over all $i \in \{1, 2, ..., n-1\}$, we obtain

$$\sum_{i=1}^{n-1}\mathcal{D}_i = \sum_{i=1}^{n-1}\sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d+1;\ |\operatorname{Stag}(w)|=s;\ w_i>w_{i+1}}} x_{w_1}x_{w_2}\cdots x_{w_n}$$

$$= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d+1;\ |\operatorname{Stag}(w)|=s}} \underbrace{\sum_{\substack{i\in\{1,2,\ldots,n-1\};\\ w_i>w_{i+1}}} x_{w_1}x_{w_2}\cdots x_{w_n}}_{=|\{i\in\{1,2,\ldots,n-1\}\ |\ w_i>w_{i+1}\}|x_{w_1}x_{w_2}\cdots x_{w_n}}$$

$$= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d+1;\ |\operatorname{Stag}(w)|=s}} \underbrace{|\{i\in\{1,2,...,n-1\}\ \mid\ w_i>w_{i+1}\}|}_{=|\operatorname{Des} w|=d+1} x_{w_1}x_{w_2}\cdots x_{w_n}$$

$$= (d+1)\underbrace{\sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d+1;\ |\operatorname{Stag}(w)|=s}} x_{w_1}x_{w_2}\cdots x_{w_n}}_{\substack{=X_{n,d+1,s}\\ \text{(by (13.88.1), applied to } d+1 \text{ instead of } d)}}$$

$$= (d+1)\,X_{n,d+1,s}. \qquad (13.88.8)$$

- Similarly, we can see that

$$\sum_{i=1}^{n-1}\mathcal{S}_i = (s+1)\,X_{n,d,s+1}. \qquad (13.88.9)$$

- Similarly, we can see that

$$\sum_{i=1}^{n-1}\mathcal{A}_i = (n-1-d-s)\,X_{n,d,s}. \qquad (13.88.10)$$

[703]

Now, summing the equality (13.88.7) over all $i \in \{1, 2, ..., n-1\}$ yields

$$\sum_{i=1}^{n-1}(\mathcal{D}_i + \mathcal{S}_i + \mathcal{A}_i) = \sum_{i=1}^{n-1}\sum_{e=0}^{d}\sum_{t=0}^{s} X_{i,e,t}X_{n-i,d-e,s-t}.$$

[703] In proving this, we have to observe that $|\{i \in \{1, 2, ..., n-1\} \mid w_i < w_{i+1}\}| = n - 1 - |\operatorname{Des} w| - |\operatorname{Stag} w|$ for every $w = (w_1, w_2, \ldots, w_n) \in \{1, 2, 3, ...\}^n$. This is clear from realizing that the sets $\{i \in \{1, 2, ..., n-1\} \mid w_i < w_{i+1}\}$, $\operatorname{Des} w$ and $\operatorname{Stag} w$ are disjoint and their union is $\{1, 2, ..., n-1\}$.

Hence,

$$\begin{aligned}
&\sum_{i=1}^{n-1}\sum_{e=0}^{d}\sum_{t=0}^{s} X_{i,e,t}X_{n-i,d-e,s-t} \\
&= \sum_{i=1}^{n-1}\left(\mathcal{D}_i+\mathcal{S}_i+\mathcal{A}_i\right) = \underbrace{\sum_{i=1}^{n-1}\mathcal{D}_i}_{\substack{=(d+1)X_{n,d+1,s} \\ \text{(by (13.88.8))}}} + \underbrace{\sum_{i=1}^{n-1}\mathcal{S}_i}_{\substack{=(s+1)X_{n,d,s+1} \\ \text{(by (13.88.9))}}} + \underbrace{\sum_{i=1}^{n-1}\mathcal{A}_i}_{\substack{=(n-1-d-s)X_{n,d,s} \\ \text{(by (13.88.10))}}} \\
&= (d+1)\,X_{n,d+1,s} + (s+1)\,X_{n,d,s+1} + (n-1-d-s)\,X_{n,d,s}.
\end{aligned}$$

This proves (13.88.2).

In solving Exercise 2.9.11(b), we shall use the following trick to simplify our life. Recall that there is a canonical ring homomorphism $\varphi : \mathbb{Z} \to \mathbf{k}$. This homomorphism gives rise to a ring homomorphism $\varphi[[\mathbf{x}]] : \mathbb{Z}[[\mathbf{x}]] \to \mathbf{k}[[\mathbf{x}]]$, and this latter homomorphism $\varphi[[\mathbf{x}]]$ sends $\Lambda_{\mathbb{Z}}$ to $\Lambda_{\mathbf{k}}$; that is, we have $(\varphi[[\mathbf{x}]])(\Lambda_{\mathbb{Z}}) \subset \Lambda_{\mathbf{k}}$. Moreover, it is clear that (for any nonnegative integers d and s) the ring homomorphism $\varphi[[\mathbf{x}]]$ sends the element $X_{n,d,s}$ of $\mathbb{Z}[[\mathbf{x}]]$ to the element $X_{n,d,s}$ of $\mathbf{k}[[\mathbf{x}]]$ (because the definition of $X_{n,d,s}$ is functorial in the base ring $\mathbf{k}$). Therefore, if we can prove (for given nonnegative integers d and s) that the element $X_{n,d,s}$ of $\mathbb{Z}[[\mathbf{x}]]$ belongs to $\Lambda_{\mathbb{Z}}$, then it will automatically follow that the element $X_{n,d,s}$ of $\mathbf{k}[[\mathbf{x}]]$ belongs to $(\varphi[[\mathbf{x}]])(\Lambda_{\mathbb{Z}}) \subset \Lambda_{\mathbf{k}}$; this will complete the solution to Exercise 2.9.11(b). Hence, in order to solve Exercise 2.9.11(b), it only remains to prove (for any nonnegative integers d and s) that the element $X_{n,d,s}$ of $\mathbb{Z}[[\mathbf{x}]]$ belongs to $\Lambda_{\mathbb{Z}}$. In other words, it only remains to solve Exercise 2.9.11(b) in the case of $\mathbf{k} = \mathbb{Z}$. Hence, in solving Exercise 2.9.11(b), we can WLOG assume that $\mathbf{k} = \mathbb{Z}$. Assume this.

Now, we are going to solve Exercise 2.9.11(b) by strong induction over $n + d$. So (for the induction step) we need to show that $X_{n,d,s} \in \Lambda$, and we can assume (as the induction hypothesis) that $X_{n',d',s'} \in \Lambda$ is already known to hold for any nonnegative integers n', d' and s' satisfying $n' + d' < n + d$.

We must be in one of the following two cases:

Case 1: We have $d > 0$.

Case 2: We have $d = 0$.

Let us first consider Case 1. In this case, we have $d > 0$. Hence, $d - 1 \in \mathbb{N}$. We also WLOG assume that n is positive (otherwise, $X_{n,d,s}$ is a constant and thus lies in Λ for sure). Applying (13.88.2) to $d - 1$ instead of d, we obtain

$$dX_{n,d,s} + (s+1)\,X_{n,d-1,s+1} + (n-d-s)\,X_{n,d-1,s} = \sum_{i=1}^{n-1}\sum_{e=0}^{d-1}\sum_{t=0}^{s} X_{i,e,t}X_{n-i,d-1-e,s-t}.$$

Thus,

$$dX_{n,d,s} = \sum_{i=1}^{n-1}\sum_{e=0}^{d-1}\sum_{t=0}^{s} X_{i,e,t}X_{n-i,d-1-e,s-t} - (s+1)\,X_{n,d-1,s+1} + (n-d-s)\,X_{n,d-1,s}. \tag{13.88.11}$$

Each of the power series $X_{i,e,t}$, $X_{n-i,d-1-e,s-t}$, $X_{n,d-1,s+1}$ and $X_{n,d-1,s}$ on the right hand side of this equality is already known to lie in Λ (by the induction hypothesis). Hence, the right hand side of (13.88.11) lies in Λ (since Λ is a ring), and thus (13.88.11) shows that $dX_{n,d,s} \in \Lambda$. Since $d > 0$, this yields $X_{n,d,s} \in \Lambda$ (because if a power series $Q \in \mathbb{Z}[[\mathbf{x}]]$ satisfies $dQ \in \Lambda$, then Q must belong to Λ itself[704]). Hence, the induction step is complete in Case 1.

Let us now consider Case 2. In this case, we have $d = 0$. Hence, $X_{n,d,s} = X_{n,0,s}$.

We shall now show that

$$X_{n,0,s} = \sum_{\substack{\lambda\in\operatorname{Par}_n; \\ \ell(\lambda)=n-s}} m_\lambda. \tag{13.88.12}$$

[704] It is here that we are using our assumption that $\mathbf{k} = \mathbb{Z}$.

Proof of (13.88.12): Summing up the equality (2.1.1) over all $\lambda \in \operatorname{Par}_n$ satisfying $\ell(\lambda) = n - s$, we obtain

$$\sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \ell(\lambda) = n-s}} m_\lambda = \sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \ell(\lambda) = n-s}} \sum_{\alpha \in \mathfrak{S}_{(\infty)}\lambda} \mathbf{x}^\alpha . \tag{13.88.13}$$

On the other hand, the equality (13.88.1) (applied to 0 instead of d) yields

$$X_{n,0,s} = \sum_{\substack{w=(w_1,w_2,\ldots,w_n) \in \{1,2,3,\ldots\}^n; \\ |\operatorname{Des}(w)|=0; \ |\operatorname{Stag}(w)|=s}} x_{w_1} x_{w_2} \cdots x_{w_n} . \tag{13.88.14}$$

The condition $|\operatorname{Des}(w)| = 0$ on an n-tuple $w = (w_1, w_2, \ldots, w_n) \in \{1, 2, 3, \ldots\}^n$ is equivalent to $w_1 \leq w_2 \leq \ldots \leq w_n$, and therefore (13.88.14) rewrites as

$$X_{n,0,s} = \sum_{\substack{w=(w_1,w_2,\ldots,w_n) \in \{1,2,3,\ldots\}^n; \\ w_1 \leq w_2 \leq \ldots \leq w_n; \ |\operatorname{Stag}(w)|=s}} x_{w_1} x_{w_2} \cdots x_{w_n} . \tag{13.88.15}$$

For an n-tuple $w = (w_1, w_2, \ldots, w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $w_1 \leq w_2 \leq \ldots \leq w_n$, the condition $|\operatorname{Stag}(w)| = s$ is equivalent to the condition that $|\{w_1, w_2, \ldots, w_n\}| = n - s$. Hence, (13.88.15) rewrites as

$$X_{n,0,s} = \sum_{\substack{w=(w_1,w_2,\ldots,w_n) \in \{1,2,3,\ldots\}^n; \\ w_1 \leq w_2 \leq \ldots \leq w_n; \ |\{w_1,w_2,\ldots,w_n\}|=n-s}} x_{w_1} x_{w_2} \cdots x_{w_n} . \tag{13.88.16}$$

For any fixed weak composition $\alpha = (\alpha_1, \alpha_2, \alpha_3, \ldots)$, the monomial $\mathbf{x}^\alpha$ occurs **at most once** on the right hand side of (13.88.16) (because there is at most one way to write $\mathbf{x}^\alpha$ in the form $x_{w_1} x_{w_2} \cdots x_{w_n}$ for a $w = (w_1, w_2, \ldots, w_n) \in \{1, 2, 3, \ldots\}^n$ satisfying $w_1 \leq w_2 \leq \ldots \leq w_n$). We can easily tell whether it occurs or not by looking at the size $|\alpha|$ of α and the number of positive integers i satisfying $\alpha_i \neq 0$: Namely, the monomial $\mathbf{x}^\alpha$ for a fixed weak composition $\alpha = (\alpha_1, \alpha_2, \alpha_3, \ldots)$ occurs on the right hand side of (13.88.16) if and only if it satisfies the following two properties:

- We have $|\alpha| = n$.
- There are precisely $n - s$ positive integers i satisfying $\alpha_i \neq 0$.

Thus, the monomials satisfying these two properties occur exactly once on the right hand side of (13.88.16), while all other monomials don't occur there at all. But the same conclusion can be reached for the right hand side of (13.88.13). Hence, for any fixed weak composition $\alpha = (\alpha_1, \alpha_2, \alpha_3, \ldots)$, the monomial $\mathbf{x}^\alpha$ occurs on the right hand side of (13.88.16) precisely as often as it occurs on the right hand side of (13.88.13). Hence, the right hand side of (13.88.16) equals the right hand side of (13.88.13). Therefore, the left hand side of (13.88.16) also equals the left hand side of (13.88.13). In other words, $X_{n,0,s} = \sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \ell(\lambda)=n-s}} m_\lambda$. This proves (13.88.12).

Now, (13.88.12) yields $X_{n,0,s} = \sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \ell(\lambda)=n-s}} \underbrace{m_\lambda}_{\in \Lambda} \in \Lambda$, so that $X_{n,d,s} = X_{n,0,s} \in \Lambda$. This completes the induction step in Case 2.

Thus, the induction step is complete in both Cases 1 and 2. This finally completes the induction step. Exercise 2.9.11(b) is thus solved.

(a) *First solution of Exercise 2.9.11(a):* Recall the power series $X_{n,d,s}$ defined in Exercise 2.9.11(b) for any $d \in \mathbb{N}$ and $s \in \mathbb{N}$. Exercise 2.9.11(b) yields that $X_{n,k,0} \in \Lambda$. But an n-tuple w is Smirnov if and only if its stagnation set $\operatorname{Stag}(w)$ is empty, i.e., if and only if $|\operatorname{Stag}(w)| = 0$. Hence, $X_{n,k,0}$ is the sum of the monomials $x_{w_1} x_{w_2} \cdots x_{w_n}$ over all Smirnov n-tuples $w \in \{1, 2, 3, \ldots\}^n$ satisfying $|\operatorname{Des}(w)| = k$. This shows that $X_{n,k,0} = X_{n,k}$. Thus, $X_{n,k} = X_{n,k,0} \in \Lambda$, so that Exercise 2.9.11(a) is solved.

Second solution of Exercise 2.9.11(a): Here is an alternative solution to Exercise 2.9.11(a), which avoids using part (b). It is an application of [199, proof of Theorem 4.5] to our special setting.

We proceed similarly to the proof of Proposition 2.2.4: It suffices to show that for every positive integer p, the power series $X_{n,k}$ is invariant under swapping the variables x_p and x_{p+1}. So let us fix a positive integer p.

Let $S_{n,k}$ denote the set of all Smirnov n-tuples $w \in \{1,2,3,\ldots\}^n$ satisfying $|\operatorname{Des}(w)| = k$. Then, the definition of $X_{n,k}$ rewrites as follows:

$$X_{n,k} = \sum_{w=(w_1,w_2,\ldots,w_n)\in S_{n,k}} x_{w_1}x_{w_2}\ldots x_{w_n}. \tag{13.88.17}$$

For every $w \in S_{n,k}$, let $\mathbf{x}_w$ denote the monomial $x_{w_1}x_{w_2}\ldots x_{w_n}$, where w is written in the form $w = (w_1, w_2, \ldots, w_n)$. Then, (13.88.17) rewrites as

$$X_{n,k} = \sum_{w\in S_{n,k}} \mathbf{x}_w. \tag{13.88.18}$$

We need to show that this power series $X_{n,k}$ is invariant under swapping the variables x_p and x_{p+1}. In order to do so, it is clearly enough to provide an involution $J : S_{n,k} \to S_{n,k}$ which has the property that for every $w \in S_{n,k}$, the monomial $\mathbf{x}_{J(w)}$ is obtained from the monomial $\mathbf{x}_w$ by swapping the variables x_p and x_{p+1}.

To define the involution J, we introduce some notations. If $w = (w_1, w_2, \ldots, w_n) \in \{1,2,3,\ldots\}^n$ is any n-tuple, then a nonempty interval I of $\{1,2,\ldots,n\}$ will be called a $(p,p+1)$-*interval* of w if every $i \in I$ satisfies $w_i \in \{p,p+1\}$. A $(p,p+1)$-*run* of w will mean a $(p,p+1)$-interval of w maximal with respect to inclusion. For instance, if $n = 9$, $w = (3,1,2,5,4,2,3,2,4)$ and $p = 2$, then the $(p,p+1)$-intervals of w are $\{1\}$, $\{3\}$, $\{6\}$, $\{7\}$, $\{8\}$, $\{6,7\}$, $\{7,8\}$ and $\{6,7,8\}$ (since the letters of w belonging to $\{p,p+1\}$ are the 1-st, 3-rd, the 6-th, the 7-th and the 8-th letter), while only $\{1\}$, $\{3\}$ and $\{6,7,8\}$ are $(p,p+1)$-runs of w.

An interval of $\{1,2,\ldots,n\}$ is said to be *even* if it has even size, and *odd* if it has odd size.

It is easy to see that if $w = (w_1, w_2, \ldots, w_n) \in \{1,2,3,\ldots\}^n$ is any Smirnov n-tuple, and $\{a+1, a+2, \ldots, b\}$ is any $(p,p+1)$-interval of w, then the $(b-a)$-tuple $(w_{a+1}, w_{a+2}, \ldots, w_b)$ alternates between p's and $(p+1)$'s, that is, has one of the forms

$$(p, p+1, p, p+1, p, \ldots, p+1) \qquad \text{and} \qquad (p+1, p, p+1, p, p+1, \ldots, p)$$

(if $b-a$ is even) or one of the forms

$$(p, p+1, p, p+1, p, \ldots, p) \qquad \text{and} \qquad (p+1, p, p+1, p, p+1, \ldots, p+1)$$

(if $b-a$ is odd).

Now, we define a map $J : S_{n,k} \to S_{n,k}$ as follows: Let $w = (w_1, w_2, \ldots, w_n) \in S_{n,k}$. We know that w is Smirnov and satisfies $|\operatorname{Des}(w)| = k$. It is clear that the $(p,p+1)$-runs of w are disjoint and even separated from each other by at least 1 (this means that if α and β are elements of two distinct $(p,p+1)$-runs of w, then $|\alpha - \beta| > 1$). For every $i \in \{1,2,\ldots,n\}$, define a positive integer w_i' as follows:

- If i belongs to an odd $(p,p+1)$-run of w, then set $w_i' = \begin{cases} p+1, & \text{if } w_i = p; \\ p, & \text{if } w_i = p+1 \end{cases}$.
- Otherwise, set $w_i' = w_i$.

Thus, we have defined an n-tuple $(w_1', w_2', \ldots, w_n')$ of positive integers.[705] Denote this n-tuple $(w_1', w_2', \ldots, w_n')$ by w'. The reader can easily check that this new n-tuple w' is again Smirnov and satisfies $|\operatorname{Des}(w')| = k$. In other words, $w' \in S_{n,k}$. Now, set $J(w) = w'$. We have thus defined a map $J : S_{n,k} \to S_{n,k}$. It is easy to see that, for every $w \in S_{n,k}$, the $(p,p+1)$-runs of $J(w)$ are exactly the $(p,p+1)$-runs of w, and applying the map J to $J(w)$ precisely reverts the changes made by the map J to w. In other words, $J \circ J = \mathrm{id}$, so that the map J is an involution. Finally, it is straightforward to see that for every $w \in S_{n,k}$, we have the following facts:

1. The number of entries equal to $p+1$ in $J(w)$ equals the number of entries equal to p in w.
2. The number of entries equal to p in $J(w)$ equals the number of entries equal to $p+1$ in w.
3. For every $j \in \{1,2,3,\ldots\} \setminus \{p,p+1\}$, the number of entries equal to j in $J(w)$ equals the number of entries equal to j in w.

[705] Informally speaking, $(w_1', w_2', \ldots, w_n')$ is simply obtained by changing those p's and $p+1$'s in w whose positions belong to odd $(p,p+1)$-runs of w into $p+1$'s and p's, respectively, while leaving all other entries of w intact. For instance, in our above example of $n = 9$, $w = (3,1,2,5,4,2,3,2,4)$ and $p = 2$, we would have $(w_1', w_2', \ldots, w_n') = (2,1,3,5,4,3,2,3,4)$. (All letters 2 and 3 have been changed here because all $(p,p+1)$-runs of this w were odd.) For another example, if $n = 5$, $w = (2,3,1,5,2)$ and $p = 2$, then $(w_1', w_2', \ldots, w_n') = (2,3,1,5,3)$ (the first two letters are unchanged since the $(p,p+1)$-run $\{1,2\}$ is even).

[706] These three statements, combined, show that for every $w \in S_{n,k}$, the monomial $\mathbf{x}_{J(w)}$ is obtained from the monomial $\mathbf{x}_w$ by swapping the variables x_p and x_{p+1}. This concludes our solution of Exercise 2.9.11(a).

Remark: We could have given an alternative solution to Exercise 2.9.11(b) that would still rely on (13.88.2), but proceed by induction on $n+s$ (rather than $n+d$) and handle the case $s=0$ separately (rather than the case $d=0$ as we did). In the case $s=0$, the assertion of Exercise 2.9.11(b) follows from Exercise 2.9.11(a). (But this only works combined with a solution to Exercise 2.9.11(a) that does not rely on Exercise 2.9.11(b).)

(c) For every $d \in \mathbb{N}$, $s \in \mathbb{N}$ and $i \in \{1,2,...,n-1\}$, we define the power series $\mathcal{D}_i$, $\mathcal{S}_i$ and $\mathcal{A}_i$ as in the solution to Exercise 2.9.11(b) above.

Let us first show that if n is a positive integer, then any $d \in \mathbb{N}$ and $s \in \mathbb{N}$ satisfy

$$(d+1)\,U_{n,d+1,s} + (s+1)\,U_{n,d,s+1} + (n-1-d-s)\,U_{n,d,s} = (d+1)\,X_{n,d+1,s}. \tag{13.88.19}$$

Proof of (13.88.19): Let n be a positive integer. Let $d \in \mathbb{N}$ and $s \in \mathbb{N}$. Let $i \in \{1,2,...,n-1\}$ be arbitrary.

Before we make any new definitions, let us recall a statement that we have shown during our proof of (13.88.2) (back when we were solving Exercise 2.9.11(b)): The power series $\mathcal{D}_i \in \mathbf{k}[[\mathbf{x}]]$ is the sum of the monomials $x_{w_1}x_{w_2}\cdots x_{w_n}$ over all n-tuples $w=(w_1,w_2,...,w_n) \in \{1,2,3,\ldots\}^n$ satisfying $|(\operatorname{Des}(w)) \setminus \{i\}| = d$, $|(\operatorname{Stag}(w)) \setminus \{i\}| = s$ and $w_i > w_{i+1}$. Written as a formula, this yields

$$\mathcal{D}_i = \sum_{\substack{w=(w_1,w_2,...,w_n)\in\{1,2,3,\ldots\}^n;\\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s;\\ w_i>w_{i+1}}} x_{w_1}x_{w_2}\cdots x_{w_n}.$$

Applying this to $n-i$ instead of i, we obtain

$$\mathcal{D}_{n-i} = \sum_{\substack{w=(w_1,w_2,...,w_n)\in\{1,2,3,\ldots\}^n;\\ |(\operatorname{Des}(w))\setminus\{n-i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{n-i\}|=s;\\ w_{n-i}>w_{n-i+1}}} x_{w_1}x_{w_2}\cdots x_{w_n}. \tag{13.88.20}$$

Now, let us make some more definitions:

- Define a power series $\mathcal{D}'_i \in \mathbf{k}[[\mathbf{x}]]$ as the sum of the monomials $x_{w_1}x_{w_2}\cdots x_{w_n}$ over all n-tuples $w=(w_1,w_2,...,w_n) \in \{1,2,3,\ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d+1$, $|\operatorname{Stag}(w)| = s$, $w_1 < w_n$ and $w_i > w_{i+1}$.
- Define a power series $\mathcal{S}'_i \in \mathbf{k}[[\mathbf{x}]]$ as the sum of the monomials $x_{w_1}x_{w_2}\cdots x_{w_n}$ over all n-tuples $w=(w_1,w_2,...,w_n) \in \{1,2,3,\ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d$, $|\operatorname{Stag}(w)| = s+1$, $w_1 < w_n$ and $w_i = w_{i+1}$.
- Define a power series $\mathcal{A}'_i \in \mathbf{k}[[\mathbf{x}]]$ as the sum of the monomials $x_{w_1}x_{w_2}\cdots x_{w_n}$ over all n-tuples $w=(w_1,w_2,...,w_n) \in \{1,2,3,\ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d$, $|\operatorname{Stag}(w)| = s$, $w_1 < w_n$ and $w_i < w_{i+1}$.

These three power series $\mathcal{D}'_i$, $\mathcal{S}'_i$ and $\mathcal{A}'_i$ were defined in obvious analogy to the power series $\mathcal{D}_i$, $\mathcal{S}_i$ and $\mathcal{A}_i$ defined in our solution to Exercise 2.9.11(b) above. In the same way as we have proved (13.88.3) back there, we can see that

$$\mathcal{D}'_i + \mathcal{S}'_i + \mathcal{A}'_i = \sum_{\substack{w=(w_1,w_2,...,w_n)\in\{1,2,3,\ldots\}^n;\\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s;\\ w_1<w_n}} x_{w_1}x_{w_2}\cdots x_{w_n}. \tag{13.88.21}$$

But the sum on the right hand side of (13.88.21) can be rewritten in terms of more familiar sums. In fact, the n-tuples $w=(w_1,w_2,...,w_n) \in \{1,2,3,\ldots\}^n$ are in bijection with the pairs (u,v) consisting of an i-tuple $u=(u_1,u_2,...,u_i) \in \{1,2,3,\ldots\}^i$ and an $(n-i)$-tuple $v=(v_1,v_2,...,v_{n-i}) \in \{1,2,3,\ldots\}^{n-i}$. This bijection sends an n-tuple $(w_1,w_2,...,w_n)$ to the pair $((w_1,w_2,...,w_i),(w_{i+1},w_{i+2},...,w_n))$, and has the property that $|(\operatorname{Des}(w)) \setminus \{i\}| = |\operatorname{Des}(u)| + |\operatorname{Des}(v)|$ [707], $|(\operatorname{Stag}(w)) \setminus \{i\}| = |\operatorname{Stag}(u)| + |\operatorname{Stag}(v)|$ [708],

[706] The idea is that the map J switches the number of p's with the number of $(p+1)$'s in any odd $(p,p+1)$-run, while the numbers in an even $(p,p+1)$-run are already equal to begin with.

[707] In fact, $(\operatorname{Des}(w))\setminus\{i\}$ is the union of the set $\operatorname{Des}(u)$ with the set $\operatorname{Des}(v)$ shifted by i (that is, the set $\{p+i \mid p \in \operatorname{Des}(v)\}$). This is a disjoint union, and thus we find that $|(\operatorname{Des}(w)) \setminus \{i\}| = |\operatorname{Des}(u)| + |\operatorname{Des}(v)|$ (since the set $\operatorname{Des}(v)$ shifted by i has cardinality $|\operatorname{Des}(v)|$).

[708] for similar reasons

$x_{w_1}x_{w_2}\cdots x_{w_n} = x_{u_1}x_{u_2}\cdots x_{u_i}x_{v_1}x_{v_2}\cdots x_{v_{n-i}}$, $w_1 = u_1$ and $w_n = v_{n-i}$. Hence,

$$\begin{aligned}
&\sum_{\substack{w=(w_1,w_2,\dots,w_n)\in\{1,2,3,\dots\}^n;\\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s;\\ w_1<w_n}} x_{w_1}x_{w_2}\cdots x_{w_n}\\
&= \underbrace{\sum_{\substack{u=(u_1,u_2,\dots,u_i)\in\{1,2,3,\dots\}^i;\\ v=(v_1,v_2,\dots,v_{n-i})\in\{1,2,3,\dots\}^{n-i};\\ |\operatorname{Des}(u)|+|\operatorname{Des}(v)|=d;\\ |\operatorname{Stag}(u)|+|\operatorname{Stag}(v)|=s;\\ u_1<v_{n-i}}}}_{=\sum_{\substack{v=(v_1,v_2,\dots,v_{n-i})\in\{1,2,3,\dots\}^{n-i};\\ u=(u_1,u_2,\dots,u_i)\in\{1,2,3,\dots\}^i;\\ |\operatorname{Des}(u)|+|\operatorname{Des}(v)|=d;\\ |\operatorname{Stag}(u)|+|\operatorname{Stag}(v)|=s;\\ u_1<v_{n-i}}}} \underbrace{x_{u_1}x_{u_2}\cdots x_{u_i}x_{v_1}x_{v_2}\cdots x_{v_{n-i}}}_{=x_{v_1}x_{v_2}\cdots x_{v_{n-i}}x_{u_1}x_{u_2}\cdots x_{u_i}}\\
&= \sum_{\substack{v=(v_1,v_2,\dots,v_{n-i})\in\{1,2,3,\dots\}^{n-i};\\ u=(u_1,u_2,\dots,u_i)\in\{1,2,3,\dots\}^i;\\ |\operatorname{Des}(u)|+|\operatorname{Des}(v)|=d;\\ |\operatorname{Stag}(u)|+|\operatorname{Stag}(v)|=s;\\ u_1<v_{n-i}}} x_{v_1}x_{v_2}\cdots x_{v_{n-i}}x_{u_1}x_{u_2}\cdots x_{u_i}.
\end{aligned}\tag{13.88.22}$$

On the other hand, the pairs (v,u) consisting of an $(n-i)$-tuple $v=(v_1,v_2,...,v_{n-i})\in\{1,2,3,\ldots\}^{n-i}$ and an i-tuple $u=(u_1,u_2,...,u_i)\in\{1,2,3,\ldots\}^i$ are in bijection with the n-tuples $w=(w_1,w_2,...,w_n)\in\{1,2,3,\ldots\}^n$. This bijection sends a pair (v,u) with $v=(v_1,v_2,...,v_{n-i})$ and $u=(u_1,u_2,...,u_i)$ to the n-tuple $(v_1,v_2,...,v_{n-i},u_1,u_2,...,u_i)\in\{1,2,3,\ldots\}^n$, and has the property that $|(\operatorname{Des}(w))\setminus\{n-i\}| = |\operatorname{Des}(u)| + |\operatorname{Des}(v)|$ [709], $|(\operatorname{Stag}(w))\setminus\{n-i\}| = |\operatorname{Stag}(u)|+|\operatorname{Stag}(v)|$ [710], $x_{w_1}x_{w_2}\cdots x_{w_n} = x_{v_1}x_{v_2}\cdots x_{v_{n-i}}x_{u_1}x_{u_2}\cdots x_{u_i}$, $w_{n-i+1}=u_1$ and $w_{n-i}=v_{n-i}$. We can use this bijection to transform the sum on the right hand side of (13.88.22), and obtain

$$\begin{aligned}
&\sum_{\substack{v=(v_1,v_2,\dots,v_{n-i})\in\{1,2,3,\dots\}^{n-i};\\ u=(u_1,u_2,\dots,u_i)\in\{1,2,3,\dots\}^i;\\ |\operatorname{Des}(u)|+|\operatorname{Des}(v)|=d;\\ |\operatorname{Stag}(u)|+|\operatorname{Stag}(v)|=s;\\ u_1<v_{n-i}}} x_{u_1}x_{u_2}\cdots x_{u_i}x_{v_1}x_{v_2}\cdots x_{v_{n-i}}\\
&= \sum_{\substack{w=(w_1,w_2,\dots,w_n)\in\{1,2,3,\dots\}^n;\\ |(\operatorname{Des}(w))\setminus\{n-i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{n-i\}|=s;\\ w_{n-i+1}<w_{n-i}}} x_{w_1}x_{w_2}\cdots x_{w_n}\\
&= \sum_{\substack{w=(w_1,w_2,\dots,w_n)\in\{1,2,3,\dots\}^n;\\ |(\operatorname{Des}(w))\setminus\{n-i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{n-i\}|=s;\\ w_{n-i}>w_{n-i+1}}} x_{w_1}x_{w_2}\cdots x_{w_n} = \mathcal{D}_{n-i} \qquad (\text{by (13.88.20)}).
\end{aligned}\tag{13.88.23}$$

[709] In fact, $(\operatorname{Des}(w))\setminus\{n-i\}$ is the union of the set $\operatorname{Des}(v)$ with the set $\operatorname{Des}(u)$ shifted by $n-i$ (that is, the set $\{p+(n-i)\ \mid\ p\in\operatorname{Des}(u)\}$). This is a disjoint union; thus, we find $|(\operatorname{Des}(w))\setminus\{n-i\}| = |\operatorname{Des}(u)| + |\operatorname{Des}(v)|$ (since the set $\operatorname{Des}(u)$ shifted by $n-i$ has cardinality $|\operatorname{Des}(u)|$).

[710] for similar reasons

Now, (13.88.21) becomes

$$\begin{aligned}\mathcal{D}'_i + \mathcal{S}'_i + \mathcal{A}'_i &= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |(\operatorname{Des}(w))\setminus\{i\}|=d;\ |(\operatorname{Stag}(w))\setminus\{i\}|=s;\\ w_1<w_n}} x_{w_1}x_{w_2}\cdots x_{w_n} \\ &= \sum_{\substack{v=(v_1,v_2,\ldots,v_{n-i})\in\{1,2,3,\ldots\}^{n-i};\\ u=(u_1,u_2,\ldots,u_i)\in\{1,2,3,\ldots\}^{i};\\ |\operatorname{Des}(u)|+|\operatorname{Des}(v)|=d;\\ |\operatorname{Stag}(u)|+|\operatorname{Stag}(v)|=s;\\ u_1<v_{n-i}}} x_{v_1}x_{v_2}\cdots x_{v_{n-i}}x_{u_1}x_{u_2}\cdots x_{u_i} \qquad (\text{by } (13.88.22)) \\ &= \mathcal{D}_{n-i}. \end{aligned} \tag{13.88.24}$$

Now, let us forget that we fixed i. We thus have defined $\mathcal{D}'_i$, $\mathcal{S}'_i$ and $\mathcal{A}'_i$ and proven the equality (13.88.24) for all $i \in \{1,2,...,n-1\}$.

Now, let us take a closer look at the sums $\sum_{i=1}^{n-1}\mathcal{D}'_i$, $\sum_{i=1}^{n-1}\mathcal{S}'_i$ and $\sum_{i=1}^{n-1}\mathcal{A}'_i$:

- Similarly to how we proved (13.88.8), we can show that

$$\sum_{i=1}^{n-1}\mathcal{D}'_i = (d+1)\,U_{n,d+1,s}. \tag{13.88.25}$$

- Similarly to how we proved (13.88.9), we can see that

$$\sum_{i=1}^{n-1}\mathcal{S}'_i = (s+1)\,U_{n,d,s+1}. \tag{13.88.26}$$

- Similarly to how we proved (13.88.10), we can see that

$$\sum_{i=1}^{n-1}\mathcal{A}'_i = (n-1-d-s)\,U_{n,d,s}. \tag{13.88.27}$$

Now, summing the equality (13.88.24) over all $i \in \{1,2,...,n-1\}$ yields

$$\sum_{i=1}^{n-1}\left(\mathcal{D}'_i + \mathcal{S}'_i + \mathcal{A}'_i\right) = \sum_{i=1}^{n-1}\mathcal{D}_{n-i} = \sum_{i=1}^{n-1}\mathcal{D}_i = (d+1)\,X_{n,d+1,s} \qquad (\text{by } (13.88.8)).$$

Hence,

$$\begin{aligned}(d+1)\,X_{n,d+1,s} = \sum_{i=1}^{n-1}\left(\mathcal{D}'_i + \mathcal{S}'_i + \mathcal{A}'_i\right) &= \underbrace{\sum_{i=1}^{n-1}\mathcal{D}'_i}_{\substack{=(d+1)U_{n,d+1,s}\\ (\text{by } (13.88.25))}} + \underbrace{\sum_{i=1}^{n-1}\mathcal{S}'_i}_{\substack{=(s+1)U_{n,d,s+1}\\ (\text{by } (13.88.26))}} + \underbrace{\sum_{i=1}^{n-1}\mathcal{A}'_i}_{\substack{=(n-1-d-s)U_{n,d,s}\\ (\text{by } (13.88.27))}} \\ &= (d+1)\,U_{n,d+1,s} + (s+1)\,U_{n,d,s+1} + (n-1-d-s)\,U_{n,d,s}.\end{aligned}$$

This proves (13.88.19).

In solving Exercise 2.9.11(c), we WLOG assume that $\mathbf{k} = \mathbb{Z}$ (for the same reason why we could assume $\mathbf{k} = \mathbb{Z}$ in solving Exercise 2.9.11(b)).

Now, we are going to prove $U_{n,d,s} \in \Lambda$ by strong induction over $n+d$. So (for the induction step) we need to show that $U_{n,d,s} \in \Lambda$, and we can assume (as the induction hypothesis) that $U_{n',d',s'} \in \Lambda$ is already known to hold for any nonnegative integers n', d' and s' satisfying $n'+d' < n+d$.

We must be in one of the following two cases:

Case 1: We have $d > 0$.

Case 2: We have $d = 0$.

In Case 1, we can proceed in the same way as in the corresponding case of the solution of Exercise 2.9.11(b) (with the only difference that we now have to use $X_{n,d,s} \in \Lambda$, but this follows from the already solved Exercise 2.9.11(b)).

Let us now consider Case 2. In this case, we have $d = 0$. We now distinguish between two subcases:

Subcase 2.1: We have $s = n-1$.

Subcase 2.2: We have $s \neq n-1$.

Let us consider Subcase 2.1 first. In this subcase, we have $s = n-1$. We will show that $U_{n,d,s} = 0$ in this subcase.

Indeed, let $w = (w_1, w_2, \ldots, w_n) \in \{1,2,3,\ldots\}^n$ be such that $|\operatorname{Des}(w)| = d$, $|\operatorname{Stag}(w)| = s$ and $w_1 < w_n$. Then, $\operatorname{Stag}(w)$ is a subset of $\{1,2,...,n-1\}$ whose cardinality is $|\operatorname{Stag}(w)| = s = n-1 = |\{1,2,...,n-1\}|$. Obviously, the only such subset is $\{1,2,...,n-1\}$ itself, and so $\operatorname{Stag}(w)$ must be $\{1,2,...,n-1\}$. Hence, every $j \in \{1,2,...,n-1\}$ satisfies $j \in \{1,2,...,n-1\} = \operatorname{Stag}(w) = \{i \in \{1,2,\ldots,n-1\} : w_i = w_{i+1}\}$ and thus $w_j = w_{j+1}$. In other words, $w_1 = w_2 = ... = w_n$. This contradicts $w_1 < w_n$.

Now, forget that we fixed w. We thus have obtained a contradiction for every $w = (w_1, w_2, \ldots, w_n) \in \{1,2,3,\ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d$, $|\operatorname{Stag}(w)| = s$ and $w_1 < w_n$. Therefore, there exists no such w. Hence, the sum on the right hand side of (2.9.10) is empty and thus equals 0. Thus, (2.9.10) rewrites as $U_{n,d,s} = 0 \in \Lambda$. Hence, the induction step is complete in Subcase 2.1.

Let us now consider Subcase 2.2. In this case, $s \neq n-1$. We will show that $U_{n,d,s} = X_{n,d,s}$ in this subcase.

Indeed, let $w = (w_1, w_2, \ldots, w_n) \in \{1,2,3,\ldots\}^n$ be such that $|\operatorname{Des}(w)| = d$ and $|\operatorname{Stag}(w)| = s$. We will show that $w_1 < w_n$.

We have $|\operatorname{Des}(w)| = d = 0$, so that the set $\operatorname{Des}(w)$ is empty. In other words, every $j \in \{1,2,...,n-1\}$ satisfies $w_j \leq w_{j+1}$. Hence, we have the chain of inequalities $w_1 \leq w_2 \leq ... \leq w_n$. At least one inequality in this chain must be strict (because otherwise, we would have $w_1 = w_2 = ... = w_n$, thus $w_j = w_{j+1}$ for every $j \in \{1,2,...,n-1\}$, thus $j \in \operatorname{Stag}(w)$ for every $j \in \{1,2,...,n-1\}$, which would lead to $\operatorname{Stag}(w) = \{1,2,...,n-1\}$ and thus $|\operatorname{Stag}(w)| = |\{1,2,...,n-1\}| = n-1$, in contradiction to $\operatorname{Stag}(w) = s \neq n-1$), and thus we have $w_1 < w_n$.

Now, let us forget that we fixed w. We thus have proven that every $w = (w_1, w_2, \ldots, w_n) \in \{1,2,3,\ldots\}^n$ satisfying $|\operatorname{Des}(w)| = d$ and $|\operatorname{Stag}(w)| = s$ automatically satisfies $w_1 < w_n$. Hence, the condition $w_1 < w_n$ under the summation sign "$\sum\limits_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_1<w_n}}$" is redundant (i.e., can be removed without changing the range of the summation). Thus,

$$\sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_1<w_n}} x_{w_1}x_{w_2}\cdots x_{w_n} = \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s}} x_{w_1}x_{w_2}\cdots x_{w_n} = X_{n,d,s}$$

(by (13.88.1)). Now, (2.9.10) becomes

$$U_{n,d,s} = \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_1<w_n}} x_{w_1}x_{w_2}\cdots x_{w_n} = X_{n,d,s} \in \Lambda$$

(by Exercise 2.9.11(b)). Hence, the induction step is complete in Subcase 2.2.

The induction step is thus complete in Case 1 and in each of the two Subcases 2.1 and 2.2. These are all cases, and so the induction step is finally complete. We have thus proven that

$$U_{n,d,s} \in \Lambda \qquad \text{for all positive integers } n, \text{ all } d \in \mathbb{N} \text{ and all } s \in \mathbb{N}. \tag{13.88.28}$$

In order to complete the solution of Exercise 2.9.11(c), we still need to prove that $V_{n,d,s}$ and $W_{n,d,s}$ belong to Λ for all positive integers n, all $d \in \mathbb{N}$ and all $s \in \mathbb{N}$.

Let n be a positive integer, let $d \in \mathbb{N}$ and let $s \in \mathbb{N}$. The equality (2.9.12) becomes

$$\begin{aligned}
W_{n,d,s} &= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_1>w_n}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&= \sum_{\substack{(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}((w_n,w_{n-1},\ldots,w_1))|=d;\ |\operatorname{Stag}((w_n,w_{n-1},\ldots,w_1))|=s;\\ w_n>w_1}} \underbrace{x_{w_n}x_{w_{n-1}}\cdots x_{w_1}}_{=x_{w_1}x_{w_2}\cdots x_{w_n}} \\
&\qquad \left(\text{here, we substituted } (w_n,w_{n-1},\ldots,w_1) \text{ for } w=(w_1,w_2,\ldots,w_n) \text{ in the sum}\right) \\
&= \sum_{\substack{(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}((w_n,w_{n-1},\ldots,w_1))|=d;\ |\operatorname{Stag}((w_n,w_{n-1},\ldots,w_1))|=s;\\ w_n>w_1}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}((w_n,w_{n-1},\ldots,w_1))|=d;\ |\operatorname{Stag}((w_n,w_{n-1},\ldots,w_1))|=s;\\ w_n>w_1}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ n-1-|\operatorname{Des}(w)|-|\operatorname{Stag}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_n>w_1}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&\qquad \left(\begin{array}{c}\text{since every } w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n \text{ satisfies}\\ |\operatorname{Des}((w_n,w_{n-1},\ldots,w_1))| = n-1-|\operatorname{Des}(w)|-|\operatorname{Stag}(w)|\\ \text{and } |\operatorname{Stag}((w_n,w_{n-1},\ldots,w_1))| = |\operatorname{Stag}(w)|\\ \text{(this is easily shown by observing that the set } \{1,2,...,n-1\}\\ \text{is the union of its three disjoint subsets}\\ \{i\in\{1,2,...,n-1\} \mid w_i<w_{i+1}\},\ \operatorname{Des}w \text{ and } \operatorname{Stag}w)\end{array}\right) \\
&= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=n-1-d-s;\ |\operatorname{Stag}(w)|=s;\\ w_1<w_n}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&\qquad \left(\begin{array}{c}\text{because for a } w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n \text{ satisfying}\\ |\operatorname{Stag}(w)|=s, \text{ the assertions } n-1-|\operatorname{Des}(w)|-|\operatorname{Stag}(w)|=d\\ \text{and } w_n>w_1 \text{ are equivalent to } |\operatorname{Des}(w)|=n-1-d-s \text{ and } w_1<w_n\end{array}\right) \\
&= U_{n,n-1-d-s,s} \qquad \left(\text{by (2.9.10), applied to } n-1-d-s \text{ instead of } d\right) \\
&\in \Lambda \qquad \left(\text{by (13.88.28), applied to } n-1-d-s \text{ instead of } d\right).
\end{aligned}$$

Finally, (13.88.1) becomes

$$\begin{aligned}
X_{n,d,s} &= \sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s}} x_{w_1}x_{w_2}\cdots x_{w_n} \\
&= \underbrace{\sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_1<w_n}} x_{w_1}x_{w_2}\cdots x_{w_n}}_{\substack{=U_{n,d,s}\\ \text{(by (2.9.10))}}} + \underbrace{\sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_1=w_n}} x_{w_1}x_{w_2}\cdots x_{w_n}}_{\substack{=V_{n,d,s}\\ \text{(by (2.9.11))}}} \\
&\qquad + \underbrace{\sum_{\substack{w=(w_1,w_2,\ldots,w_n)\in\{1,2,3,\ldots\}^n;\\ |\operatorname{Des}(w)|=d;\ |\operatorname{Stag}(w)|=s;\\ w_1>w_n}} x_{w_1}x_{w_2}\cdots x_{w_n}}_{\substack{=W_{n,d,s}\\ \text{(by (2.9.12))}}} \\
&= U_{n,d,s} + V_{n,d,s} + W_{n,d,s},
\end{aligned}$$

so that $V_{n,d,s} = \underbrace{X_{n,d,s}}_{\substack{\in\Lambda \\ \text{(by Exercise 2.9.11(b))}}} - \underbrace{U_{n,d,s}}_{\in\Lambda} - \underbrace{W_{n,d,s}}_{\in\Lambda} \in \Lambda - \Lambda - \Lambda \subset \Lambda$.

We have thus shown that $V_{n,d,s} \in \Lambda$ and $W_{n,d,s} \in \Lambda$. Combined with $U_{n,d,s} \in \Lambda$ (this follows from (13.88.28)), this completes the solution of Exercise 2.9.11(c).

13.89. **Solution to Exercise 2.9.13.** *Solution to Exercise 2.9.13.* We start out with two definitions:

- If m and q are integers satisfying $0 \leq q \leq m$, and if $U = (u_{i,j})_{i,j=1,2,...,m} \in \mathbf{k}^{m\times m}$ is an $m \times m$-matrix, then $\operatorname{NWsm}_q U$ will mean the matrix $(u_{i,j})_{i,j=1,2,...,q} \in \mathbf{k}^{q\times q}$. This is the submatrix of U obtained by removing all rows other than the first q rows and then removing all columns other than the first q columns.[711]
- A square matrix $(u_{i,j})_{i,j=1,2,...,m} \in \mathbf{k}^{m\times m}$ is said to be *nearly lower-triangular* if we have

$$\left(u_{i,j} = 0 \text{ for every } (i,j) \in \{1,2,...,m\}^2 \text{ satisfying } j > i+1\right).$$

  (Thus, informally, a square matrix is nearly lower-triangular if and only if all its entries above the superdiagonal are 0, where the *superdiagonal* is the set of all cells which lie just one step north of a cell on the diagonal.)

We will now show a lemma:

Lemma 13.89.1. *Let $m \in \mathbb{N}$. Let $U = (u_{i,j})_{i,j=1,2,...,m} \in \mathbf{k}^{m\times m}$ be a nearly lower-triangular $m \times m$-matrix. Then,*

$$\det U = \sum_{r=1}^{m} (-1)^{m-r} u_{m,r} \det\left(\operatorname{NWsm}_{r-1} U\right) \cdot \prod_{k=r}^{m-1} u_{k,k+1}.$$

Proof of Lemma 13.89.1. Fix some $r \in \{1,2,...,m\}$. We define the following four matrices:

- the $(r-1)\times(r-1)$-matrix $P = (u_{i,j})_{i,j=1,2,...,r-1}$, which is obtained from the matrix U by removing all rows other than the first $r-1$ rows and then removing all columns other than the first $r-1$ columns;
- the $(r-1)\times(m-r)$-matrix $Q = (u_{i,r+j})_{i=1,2,...,r-1;\ j=1,2,...,m-r}$, which is obtained from the matrix U by removing all rows other than the first $r-1$ rows and then removing all columns other than the last $m-r$ columns;
- the $(m-r)\times(r-1)$-matrix $R = (u_{r-1+i,j})_{i=1,2,...,m-r;\ j=1,2,...,r-1}$, which is obtained from the matrix U by removing all rows other than the r-th, the $(r+1)$-st, etc., the $(m-1)$-st row, and then removing all columns other than the first $r-1$ columns;
- the $(m-r)\times(m-r)$-matrix $S = (u_{r-1+i,r+j})_{i,j=1,2,...,m-r}$, which is obtained from the matrix U by removing all rows other than the r-th, the $(r+1)$-st, etc., the $(m-1)$-st row, and then removing all columns other than the last $m-r$ columns.

Now, the matrix U can be written as a block matrix as follows: $U = \begin{pmatrix} P & v & Q \\ R & w & S \\ x & y & z \end{pmatrix}$, where $\begin{pmatrix} v \\ w \\ y \end{pmatrix}$ is the r-th column of U, and where $\begin{pmatrix} x & y & z \end{pmatrix}$ is the m-th row of U. [712] Hence,

$$\begin{aligned} &(\text{the matrix obtained from } U \text{ by removing the } m\text{-th row and the } r\text{-th column}) \\ &= \begin{pmatrix} P & Q \\ R & S \end{pmatrix}. \end{aligned} \tag{13.89.1}$$

[711] The notation $\operatorname{NWsm}_q U$ stands short for "q-th northwest submatrix of U". It is the kind of submatrices whose determinants usually figure in the Sylvester criterion for the positive definiteness of a matrix.

[712] Despite being labelled with lowercase letters, v, w, x, y and z are still blocks, although each has (at least) one of its dimensions equal to 1 (and y is a 1×1-block).

But the matrix $Q = (u_{i,r+j})_{i=1,2,\ldots,r-1;\ j=1,2,\ldots,m-r}$ is the zero matrix (since U is nearly lower-triangular), and the matrices P and S are square matrices. Hence, $\begin{pmatrix} P & Q \\ R & S \end{pmatrix}$ is a block lower-triangular matrix with diagonal blocks P and S. Thus, its determinant is

$$\det \begin{pmatrix} P & Q \\ R & S \end{pmatrix} = \det P \cdot \det S \tag{13.89.2}$$

(since the determinant of a block lower-triangular matrix is known to equal the product of the determinants of its diagonal blocks).

But the matrix $S = (u_{r-1+i,r+j})_{i,j=1,2,\ldots,m-r}$ is lower-triangular (since U is nearly lower-triangular). Since it is well-known that the determinant of a lower-triangular matrix equals the product of its diagonal entries, we can therefore compute the determinant $\det S$ of S as follows:

$$\det S = \prod_{i=1}^{m-r} u_{r-1+i,r+i} = \prod_{k=r}^{m-1} u_{k,k+1} \qquad \text{(here, we have substituted } k \text{ for } r-1+i \text{ in the product)}. \tag{13.89.3}$$

Moreover, $P = \operatorname{NWsm}_{r-1} U$ (since comparing the definitions of P and of $\operatorname{NWsm}_{r-1} U$ shows that these two matrices are the same). Now, applying the map det to both sides of (13.89.1), we obtain

$$\begin{aligned} &\det (\text{the matrix obtained from } U \text{ by removing the } m\text{-th row and the } r\text{-th column}) \\ &= \det \begin{pmatrix} P & Q \\ R & S \end{pmatrix} = \det \underbrace{P}_{= \operatorname{NWsm}_{r-1} U} \cdot \underbrace{\det S}_{\substack{= \prod_{k=r}^{m-1} u_{k,k+1} \\ \text{(by (13.89.3))}}} \qquad \text{(by (13.89.2))} \\ &= \det (\operatorname{NWsm}_{r-1} U) \cdot \prod_{k=r}^{m-1} u_{k,k+1}. \end{aligned} \tag{13.89.4}$$

Now, forget that we fixed r. We can compute the determinant $\det U$ by Laplace expansion along the m-th row, thus obtaining

$$\begin{aligned} &\det U \\ &= \sum_{r=1}^{m} u_{m,r} \cdot \underbrace{(\text{the } (m,r)\text{-th cofactor of the matrix } U)}_{= (-1)^{m+r} \det(\text{the matrix obtained from } U \text{ by removing the } m\text{-th row and the } r\text{-th column})} \\ &= \sum_{r=1}^{m} u_{m,r} \cdot \underbrace{(-1)^{m+r}}_{=(-1)^{m-r}} \underbrace{\det (\text{the matrix obtained from } U \text{ by removing the } m\text{-th row and the } r\text{-th column})}_{\substack{= \det(\operatorname{NWsm}_{r-1} U) \cdot \prod_{k=r}^{m-1} u_{k,k+1} \\ \text{(by (13.89.4))}}} \\ &= \sum_{r=1}^{m} u_{m,r} \cdot (-1)^{m-r} \cdot \det (\operatorname{NWsm}_{r-1} U) \cdot \prod_{k=r}^{m-1} u_{k,k+1} = \sum_{r=1}^{m} (-1)^{m-r} u_{m,r} \det (\operatorname{NWsm}_{r-1} U) \cdot \prod_{k=r}^{m-1} u_{k,k+1}. \end{aligned}$$

This proves Lemma 13.89.1. □

Before we solve the actual exercise, we record one further identity that we will be using twice. Namely, we claim that

$$m e_m = \sum_{i=1}^{m} (-1)^{i-1} e_{m-i} p_i \qquad \text{for every } m \in \mathbb{N}. \tag{13.89.5}$$

Proof of (13.89.5): Recall the power series $H(t)$ defined in (2.4.1), and the power series $E(t)$ defined in (2.4.2). From (2.4.3), we know that $E(-t) H(t) = 1$. Differentiating both sides of this equation with respect to t, we obtain $(E(-t) H(t))' = 1' = 0$, so that

$$\begin{aligned} 0 = (E(-t) H(t))' &= \underbrace{(E(-t))'}_{=-E'(-t)} H(t) + E(-t) H'(t) \qquad \text{(by the Leibniz rule)} \\ &= -E'(-t) H(t) + E(-t) H'(t), \end{aligned}$$

and thus $E'(-t)H(t) = E(-t)H'(t)$. Hence, $\dfrac{E'(-t)}{E(-t)} = \dfrac{H'(t)}{H(t)}$.

But Exercise 2.5.21 yields $\sum_{m\geq 0} p_{m+1}t^m = \dfrac{H'(t)}{H(t)}$. Compared with $\dfrac{E'(-t)}{E(-t)} = \dfrac{H'(t)}{H(t)}$, this yields $\dfrac{E'(-t)}{E(-t)} = \sum_{m\geq 0} p_{m+1}t^m$. Substituting $-t$ for t in this equality, we obtain

$$\frac{E'(t)}{E(t)} = \sum_{m\geq 0} p_{m+1}(-t)^m = \sum_{m\geq 0} p_{m+1}(-1)^m t^m.$$

Thus,

$$\begin{aligned}
E'(t) &= \underbrace{E(t)}_{\substack{=\sum_{m\geq 0} e_m t^m \\ \text{(by the definition of } E(t))}} \cdot \left(\sum_{m\geq 0} p_{m+1}(-1)^m t^m\right) = \left(\sum_{m\geq 0} e_m t^m\right)\left(\sum_{m\geq 0} p_{m+1}(-1)^m t^m\right) \\
&= \left(\sum_{m\geq 0} p_{m+1}(-1)^m t^m\right)\left(\sum_{m\geq 0} e_m t^m\right) \\
&= \sum_{m\geq 0}\left(\sum_{i=0}^{m} p_{i+1}(-1)^i e_{m-i}\right) t^m \qquad \text{(by the definition of the product of two power series)} \\
&= \sum_{m\geq 1}\left(\sum_{i=0}^{m-1} p_{i+1}(-1)^i e_{m-1-i}\right) t^{m-1} \qquad \text{(here, we substituted } m-1 \text{ for } m \text{ in the first sum)} \\
&= \sum_{m\geq 0} \underbrace{\left(\sum_{i=0}^{m-1} p_{i+1}(-1)^i e_{m-1-i}\right)}_{\substack{=\sum_{i=1}^{m} p_i(-1)^{i-1} e_{m-i} \\ \text{(here we substituted } i-1 \text{ for } i \text{ in the sum)}}} t^{m-1} \\
&\qquad \left(\begin{array}{c}\text{here, we have added an } m=0 \text{ addend to the first sum;} \\ \text{this did not change the sum since this addend is } 0\end{array}\right) \\
&= \sum_{m\geq 0}\left(\sum_{i=1}^{m} p_i(-1)^{i-1} e_{m-i}\right) t^{m-1} = \sum_{m\geq 0}\left(\sum_{i=1}^{m} (-1)^{i-1} e_{m-i} p_i\right) t^{m-1}.
\end{aligned}$$

Compared with

$$\begin{aligned}
E'(t) &= \left(\sum_{m\geq 0} e_m t^m\right)' \qquad \left(\text{since } E(t) = \sum_{m\geq 0} e_m t^m\right) \\
&= \sum_{m\geq 0} e_m \cdot m t^{m-1} = \sum_{m\geq 0} m e_m t^{m-1},
\end{aligned}$$

this yields

$$\sum_{m\geq 0} m e_m t^{m-1} = \sum_{m\geq 0}\left(\sum_{i=1}^{m} (-1)^{i-1} e_{m-i} p_i\right) t^{m-1}.$$

Multiplying both sides of this equality by t, we obtain

$$\sum_{m\geq 0} m e_m t^m = \sum_{m\geq 0}\left(\sum_{i=1}^{m} (-1)^{i-1} e_{m-i} p_i\right) t^m.$$

Comparing coefficients in this equality of power series, we conclude that every $m \in \mathbb{N}$ satisfies

$$m e_m = \sum_{i=1}^{m} (-1)^{i-1} e_{m-i} p_i.$$

This proves (13.89.5).

Now, let us solve the exercise.

(a) We will solve Exercise 2.9.13(a) by strong induction over n. Thus, we assume (as the induction hypothesis) that

$$\det\left(A_k\right) = k!e_k \qquad \text{for all } k \in \mathbb{N} \text{ satisfying } k < n. \tag{13.89.6}$$

We now need to prove that $\det\left(A_n\right) = n!e_n$.

The matrix $A_n = \left(a_{i,j}\right)_{i,j=1,2,...,n}$ is nearly lower-triangular[713]. Hence, Lemma 13.89.1 (applied to $m = n$, $U = A_n$ and $u_{i,j} = a_{i,j}$) yields

$$\begin{aligned}
\det\left(A_n\right) &= \sum_{r=1}^{n} (-1)^{n-r} \underbrace{a_{n,r}}_{\substack{=p_{n-r+1} \\ \text{(by the definition of } a_{n,r}, \\ \text{since } n \geq r)}} \det \underbrace{\left(\operatorname{NWsm}_{r-1}\left(A_n\right)\right)}_{\substack{=A_{r-1} \\ \text{(this is easy to see by} \\ \text{the definitions of } A_n \text{ and } A_{r-1})}} \cdot \prod_{k=r}^{n-1} \underbrace{a_{k,k+1}}_{\substack{=k \\ \text{(by the definition of } a_{k,k+1}, \\ \text{since } k=(k+1)-1)}} \\
&= \sum_{r=1}^{n} (-1)^{n-r} p_{n-r+1} \underbrace{\det\left(A_{r-1}\right)}_{\substack{=(r-1)!e_{r-1} \\ \text{(by (13.89.6), applied to } k=r-1)}} \cdot \prod_{k=r}^{n-1} k \\
&= \sum_{r=1}^{n} (-1)^{n-r} p_{n-r+1} (r-1)!e_{r-1} \prod_{k=r}^{n-1} k = \sum_{r=1}^{n} (-1)^{n-r} \underbrace{(r-1)! \left(\prod_{k=r}^{n-1} k\right)}_{=(n-1)!} p_{n-r+1} e_{r-1} \\
&= (n-1)! \sum_{r=1}^{n} (-1)^{n-r} p_{n-r+1} e_{r-1} = (n-1)! \underbrace{\sum_{i=1}^{n} (-1)^{i-1} p_i e_{n-i}}_{\substack{=\sum_{i=1}^{n} (-1)^{i-1} e_{n-i} p_i = n e_n \\ \text{(because (13.89.5) (applied to } m=n) \\ \text{yields } n e_n = \sum_{i=1}^{n} (-1)^{i-1} e_{n-i} p_i)}} \\
&\qquad \text{(here, we have substituted } n-i+1 \text{ for } r \text{ in the sum)} \\
&= \underbrace{(n-1)!n}_{=n!} e_n = n!e_n.
\end{aligned}$$

This completes the induction step, and so Exercise 2.9.13(a) is solved.

(b) We will solve Exercise 2.9.13(b) by strong induction over n. Thus, we assume (as the induction hypothesis) that

$$\det\left(B_k\right) = p_k \qquad \text{for all positive integers } k \text{ satisfying } k < n. \tag{13.89.7}$$

We now need to prove that $\det\left(B_n\right) = p_n$.

[713] because for every $(i,j) \in \{1,2,...,n\}^2$ satisfying $j > i+1$, we have

$$a_{i,j} = \begin{cases} p_{i-j+1}, & \text{if } i \geq j; \\ i, & \text{if } i = j-1; \\ 0, & \text{if } i < j-1 \end{cases} = 0 \qquad (\text{since } i < j-1 \text{ (because } j > i+1)).$$

The matrix $B_n = (b_{i,j})_{i,j=1,2,\ldots,n}$ is nearly lower-triangular[714]. Hence, Lemma 13.89.1 (applied to $m = n$, $U = B_n$ and $u_{i,j} = b_{i,j}$) yields

$$\det(B_n) = \sum_{r=1}^{n} (-1)^{n-r} b_{n,r} \det \underbrace{(\mathrm{NWsm}_{r-1}(B_n))}_{\substack{=B_{r-1} \\ \text{(this is easy to see by} \\ \text{the definitions of } B_n \text{ and } B_{r-1})}} \cdot \prod_{k=r}^{n-1} \underbrace{b_{k,k+1}}_{\substack{=e_{k-(k+1)+1} \\ \text{(by the definition of } b_{k,k+1}, \\ \text{since } k+1>k\geq r\geq 1)}}$$

$$= \sum_{r=1}^{n} (-1)^{n-r} b_{n,r} \det(B_{r-1}) \cdot \prod_{k=r}^{n-1} \underbrace{e_{k-(k+1)+1}}_{=e_0=1}$$

$$= \sum_{r=1}^{n} (-1)^{n-r} b_{n,r} \det(B_{r-1}) \cdot \underbrace{\prod_{k=r}^{n-1} 1}_{=1} = \sum_{r=1}^{n} (-1)^{n-r} b_{n,r} \det(B_{r-1})$$

$$= (-1)^{n-1} \underbrace{b_{n,1}}_{\substack{=ne_n \\ \text{(by the definition} \\ \text{of } b_{n,1})}} \underbrace{\det(B_{1-1})}_{\substack{=1 \\ \text{(since } B_{1-1} \text{ is a} \\ 0\times 0\text{-matrix)}}} + \sum_{r=2}^{n} (-1)^{n-r} \underbrace{b_{n,r}}_{\substack{=e_{n-r+1} \\ \text{(by the definition of } b_{n,r}, \\ \text{since } r>1)}} \underbrace{\det(B_{r-1})}_{\substack{=p_{r-1} \\ \text{(by (13.89.7),} \\ \text{applied to } k=r-1)}}$$

$$= (-1)^{n-1} \underbrace{ne_n}_{\substack{=\sum_{i=1}^{n}(-1)^{i-1}e_{n-i}p_i \\ \text{(by (13.89.5), applied} \\ \text{to } m=n)}} + \underbrace{\sum_{r=2}^{n} (-1)^{n-r} e_{n-r+1} p_{r-1}}_{\substack{=\sum_{i=1}^{n-1}(-1)^{n-(i+1)}e_{n-i}p_i \\ \text{(here, we substituted } i+1 \text{ for } r \text{ in the sum)}}}$$

$$= (-1)^{n-1} \sum_{i=1}^{n} (-1)^{i-1} e_{n-i} p_i + \sum_{i=1}^{n-1} (-1)^{n-(i+1)} e_{n-i} p_i$$

$$= \sum_{i=1}^{n} \underbrace{(-1)^{n-1}(-1)^{i-1}}_{=(-1)^{n-i}} e_{n-i} p_i + \sum_{i=1}^{n-1} \underbrace{(-1)^{n-(i+1)}}_{=-(-1)^{n-i}} e_{n-i} p_i$$

$$= \underbrace{\sum_{i=1}^{n} (-1)^{n-i} e_{n-i} p_i}_{=\sum_{i=1}^{n-1}(-1)^{n-i}e_{n-i}p_i + (-1)^{n-n}e_{n-n}p_n} - \sum_{i=1}^{n-1} (-1)^{n-i} e_{n-i} p_i$$

$$= \sum_{i=1}^{n-1} (-1)^{n-i} e_{n-i} p_i + (-1)^{n-n} e_{n-n} p_n - \sum_{i=1}^{n-1} (-1)^{n-i} e_{n-i} p_i = \underbrace{(-1)^{n-n}}_{=1} \underbrace{e_{n-n}}_{=e_0=1} p_n = p_n.$$

This completes the induction step, and so Exercise 2.9.13(b) is solved.

Remark: The above solution follows closely the solution of Exercise 9.3 in the first author's "λ-rings: Definitions and basic properties" (`https://github.com/darijgr/lambda` , version 0.0.21), which is more or less a restatement of this exercise (since the elements of $\Lambda_{\mathbb{Z}}$ are in a 1-to-1 correspondence with unary functorial operations defined on every λ-ring).

Whenever $\ell \in \mathbb{N}$ and two partitions λ and μ of length $\leq \ell$ have the property that the transpose of the matrix $\left(h_{\lambda_i - \mu_j - i + j}\right)_{i,j=1,2,\ldots,\ell}$ is nearly lower-triangular, we can use Lemma 13.89.1 to obtain a recursive formula for the determinant of this matrix, which is $s_{\lambda/\mu}$ according to (2.4.16). This does not seem to be of much use, however.

[714] because for every $(i,j) \in \{1,2,\ldots,n\}^2$ satisfying $j > i+1$, we have

$$b_{i,j} = \begin{cases} ie_i, & \text{if } j = 1; \\ e_{i-j+1}, & \text{if } j > 1 \end{cases} = e_{i-j+1} \qquad (\text{since } j > 1 \text{ (because } j > i+1 \geq 1))$$

$$= 0 \qquad (\text{since } i-j+1 < 0 \text{ (since } j > i+1))$$

13.90. **Solution to Exercise 2.9.14.** *Solution to Exercise 2.9.14.* For any integers a and b, we define an element $\mathbf{s}(a,b)$ of Λ by

$$\mathbf{s}(a,b) = \begin{cases} s_{(a+1,1^b)}, & \text{if } a \geq 0 \text{ and } b \geq 0; \\ (-1)^b \delta_{a+b,-1}, & \text{if } a < 0 \text{ and } b \geq 0; \\ 0, & \text{if } b < 0 \end{cases} .$$

(We are introducing this $\mathbf{s}(a,b)$ chiefly for reasons of convenience: it will allow us to unify parts (b) and (c) of the exercise.)

Using the definition of $\mathbf{s}(a,b)$ and straightforward case analysis, we can see that:

$$\mathbf{s}(a,b) = s_{(a+1,1^b)} \qquad \text{for any } a \in \mathbb{N} \text{ and } b \in \mathbb{N}; \tag{13.90.1}$$

$$\mathbf{s}(a,b) = (-1)^b \delta_{a+b,-1} \qquad \text{for every negative integer } a \text{ and every } b \in \mathbb{Z}; \tag{13.90.2}$$

$$\mathbf{s}(a,0) = h_{a+1} \qquad \text{for every } a \in \mathbb{Z}; \tag{13.90.3}$$

$$\mathbf{s}(a,b) = 0 \qquad \text{for any } a \in \mathbb{Z} \text{ and any negative } b \in \mathbb{Z}. \tag{13.90.4}$$

Let us now show that

$$e_n h_m = \mathbf{s}(m, n-1) + \mathbf{s}(m-1, n) \qquad \text{for every } n \in \mathbb{Z} \text{ and every } m \in \mathbb{Z}. \tag{13.90.5}$$

Proof of (13.90.5): Let $n \in \mathbb{Z}$ and $m \in \mathbb{Z}$. It is easy to prove (13.90.5) in the case $n < 0$ (since both sides of (13.90.5) vanish in this case) and in the case $n = 0$ (here, it follows from (13.90.3)). We can therefore WLOG assume that $n > 0$. Assume this.

It is easy to prove (13.90.5) in the case $m < 0$ (in which case both sides of (13.90.5) vanish) and in the case $m = 0$ (in which case both sides of (13.90.5) equal e_n). Thus, we can WLOG assume that $m > 0$. Assume this. Since $m > 0$, we have $h_m = s_{(m)}$, so that

$$e_n \underbrace{h_m}_{=s_{(m)}} = e_n s_{(m)} = s_{(m)} e_n = \sum_{\substack{\lambda^+ : \lambda^+/(m) \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+} \qquad (\text{by (2.7.2), applied to } \lambda = (m)). \tag{13.90.6}$$

It is easy to see that there are exactly two partitions λ^+ for which $\lambda^+/(m)$ is a vertical n-strip, namely the partitions $(m, 1^n)$ and $(m+1, 1^{n-1})$. Hence, the sum $\sum_{\substack{\lambda^+ : \lambda^+/(m) \text{ is a} \\ \text{vertical } n\text{-strip}}} s_{\lambda^+}$ has exactly two addends: that for $\lambda^+ = (m, 1^n)$ and that for $\lambda^+ = (m+1, 1^{n-1})$. Thus, this sum simplifies to $s_{(m,1^n)} + s_{(m+1,1^{n-1})}$. Hence, (13.90.6) rewrites as

$$e_n h_m = s_{(m,1^n)} + s_{(m+1,1^{n-1})}. \tag{13.90.7}$$

But (13.90.1) (applied to $a = m-1$ and $b = n$) yields $\mathbf{s}(m-1,n) = s_{(m,1^n)}$. Also, (13.90.1) (applied to $a = m$ and $b = n-1$) yields $\mathbf{s}(m, n-1) = s_{(m+1,1^{n-1})}$. Thus,

$$e_n h_m = \underbrace{s_{(m,1^n)}}_{=\mathbf{s}(m-1,n)} + \underbrace{s_{(m+1,1^{n-1})}}_{=\mathbf{s}(m,n-1)} = \mathbf{s}(m-1,n) + \mathbf{s}(m,n-1) = \mathbf{s}(m,n-1) + \mathbf{s}(m-1,n).$$

This proves (13.90.5).

Let us now prove a statement which encompasses both parts (b) and (c) of Exercise 2.9.14. Namely, we are going to prove that

$$\sum_{i=0}^{b} (-1)^i h_{a+i+1} e_{b-i} = \mathbf{s}(a,b) \qquad \text{for any } a \in \mathbb{Z} \text{ and } b \in \mathbb{Z}. \tag{13.90.8}$$

Proof of (13.90.8): Let $a \in \mathbb{Z}$ and $b \in \mathbb{Z}$. We WLOG assume that $b \in \mathbb{N}$ (since otherwise, the left hand side of (13.90.8) is an empty sum, and the right hand side is 0 by definition). For every $i \in \{0, 1, ..., b\}$, we have

$$h_{a+i+1} e_{b-i} = e_{b-i} h_{a+i+1} = \mathbf{s}\left(\underbrace{a+i+1}_{=a+(i+1)}, \underbrace{b-i-1}_{=b-(i+1)}\right) + \mathbf{s}\left(\underbrace{(a+i+1)-1}_{=a+i}, b-i\right)$$
$$\text{(by (13.90.5), applied to } n = b-i \text{ and } m = a+i+1\text{)}$$
$$= \mathbf{s}\left(a+(i+1), b-(i+1)\right) + \mathbf{s}\left(a+i, b-i\right). \tag{13.90.9}$$

Now,

$$\sum_{i=0}^{b} (-1)^i \underbrace{h_{a+i+1} e_{b-i}}_{\substack{=\mathbf{s}(a+(i+1),b-(i+1))+\mathbf{s}(a+i,b-i) \\ \text{(by (13.90.9))}}} = \sum_{i=0}^{b} \underbrace{(-1)^i \left(\mathbf{s}\left(a+(i+1), b-(i+1)\right) + \mathbf{s}\left(a+i, b-i\right)\right)}_{\substack{=(-1)^i \mathbf{s}(a+(i+1),b-(i+1))+(-1)^i \mathbf{s}(a+i,b-i) \\ =(-1)^i \mathbf{s}(a+(i+1),b-(i+1))-(-1)^{i-1} \mathbf{s}(a+i,b-i)}}$$
$$= \sum_{i=0}^{b} \left((-1)^i \mathbf{s}\left(a+(i+1), b-(i+1)\right) - (-1)^{i-1} \mathbf{s}\left(a+i, b-i\right)\right)$$
$$= (-1)^b \mathbf{s}\left(a+(b+1), \underbrace{b-(b+1)}_{=-1}\right) - \underbrace{(-1)^{0-1}}_{=-1} \mathbf{s}\left(\underbrace{a+0}_{=a}, \underbrace{b-0}_{=b}\right)$$
$$\text{(by the telescope principle)}$$
$$= (-1)^b \underbrace{\mathbf{s}(a,-1)}_{\substack{=0 \\ \text{(by (13.90.4))}}} - (-1)\mathbf{s}(a,b) = -(-1)\mathbf{s}(a,b) = \mathbf{s}(a,b).$$

This proves (13.90.8).

Here is a modified version of (13.90.8) which will be used in our solution of Exercise 2.9.14(d) further below: For any $a \in \mathbb{Z}$, $b \in \mathbb{Z}$ and $c \in \mathbb{Z}$ satisfying $c \geq b$, we have

$$\sum_{k=0}^{c} (-1)^k h_{a+k+1} e_{b-k} = \mathbf{s}(a,b). \tag{13.90.10}$$

[715]

Now, the first three parts of Exercise 2.9.14 are as good as solved: The claim of Exercise 2.9.14(a) has already been proven in (13.90.7), and the claims of Exercise 2.9.14(b) and Exercise 2.9.14(c) follow from (13.90.8).

Before we come to the solution of Exercise 2.9.14(d), we simplify our life by introducing another definition. Namely, let us define a $\mathbf{k}$-module endomorphism $\overline{\operatorname{id}}$ of Λ by $\overline{\operatorname{id}} = \operatorname{id}_\Lambda - u\epsilon$. Then, it is easy to see that

[715] *Proof of (13.90.10):* Let $a \in \mathbb{Z}$, $b \in \mathbb{Z}$ and $c \in \mathbb{Z}$ be such that $c \geq b$. We WLOG assume that $b \geq 0$ (since otherwise, both sides of (13.90.10) vanish). Then,

$$\sum_{k=0}^{c} (-1)^k h_{a+k+1} e_{b-k} = \sum_{k=0}^{b} (-1)^k h_{a+k+1} e_{b-k} + \sum_{k=b+1}^{c} (-1)^k h_{a+k+1} \underbrace{e_{b-k}}_{\substack{=0 \\ \text{(since } b-k<0 \\ \text{(since } k>b))}}$$
$$= \sum_{k=0}^{b} (-1)^k h_{a+k+1} e_{b-k} + \underbrace{\sum_{k=b+1}^{c} (-1)^k h_{a+k+1} 0}_{=0}$$
$$= \sum_{k=0}^{b} (-1)^k h_{a+k+1} e_{b-k} = \sum_{i=0}^{b} (-1)^i h_{a+i+1} e_{b-i} = \mathbf{s}(a,b) \qquad \text{(by (13.90.8))}.$$

This proves (13.90.10).

$\overline{\operatorname{id}}(s_\lambda) = s_\lambda$ for every nonempty partition λ, whereas $\overline{\operatorname{id}}(c) = 0$ for every $c \in \mathbf{k}$. Now, straightforward computation shows that

$$\overline{\operatorname{id}}(\mathbf{s}(a,b)) = s_{(a+1,1^b)} \qquad \text{for all } a \in \mathbb{N} \text{ and } b \in \mathbb{N}; \tag{13.90.11}$$

$$\overline{\operatorname{id}}(\mathbf{s}(a,b)) = 0 \qquad \text{for every } (a,b) \in \mathbb{Z}^2 \text{ satisfying } (a,b) \notin \mathbb{N}^2. \tag{13.90.12}$$

But every $x \in \Lambda$ satisfies

$$\Delta x - 1 \otimes x - x \otimes 1 = \left(\overline{\operatorname{id}} \otimes \overline{\operatorname{id}}\right)(\Delta x) - \epsilon(x) \cdot 1 \otimes 1 \qquad \text{in } \Lambda \otimes \Lambda. \tag{13.90.13}$$

(This is an identity which holds not only in Λ but in every $\mathbf{k}$-bialgebra, and which is proven by applying the bialgebra axioms.)

(d) Recall that Λ is a $\mathbf{k}$-bialgebra. Hence, $\Delta : \Lambda \to \Lambda \otimes \Lambda$ is a $\mathbf{k}$-algebra homomorphism.

We can rewrite Proposition 2.3.6(ii) as follows: Every $n \in \mathbb{N}$ satisfies

$$\Delta e_n = \sum_{i=0}^{n} e_i \otimes e_{n-i}. \tag{13.90.14}$$

Thus, every $n \in \mathbb{N}$ satisfies

$$\Delta e_n = \sum_{i \in \mathbb{N}} e_i \otimes e_{n-i}. \tag{13.90.15}$$

[716] Similarly, every $n \in \mathbb{N}$ satisfies

$$\Delta h_n = \sum_{i \in \mathbb{N}} h_i \otimes h_{n-i}. \tag{13.90.16}$$

Let $a \in \mathbb{N}$ and $b \in \mathbb{N}$. Exercise 2.9.14(b) yields $\sum_{i=0}^{b} (-1)^i h_{a+i+1} e_{b-i} = s_{(a+1,1^b)}$, so that

$$s_{(a+1,1^b)} = \sum_{i=0}^{b} (-1)^i h_{a+i+1} e_{b-i} = \sum_{k=0}^{b} (-1)^k h_{a+k+1} e_{b-k}$$

[716] Indeed, (13.90.15) follows from (13.90.14), because

$$\sum_{i \in \mathbb{N}} e_i \otimes e_{n-i} = \sum_{i=0}^{n} e_i \otimes e_{n-i} + \sum_{i=n+1}^{\infty} e_i \otimes \underbrace{e_{n-i}}_{\substack{=0 \\ (\text{since } n-i<0)}} = \sum_{i=0}^{n} e_i \otimes e_{n-i} + \underbrace{\sum_{i=n+1}^{\infty} e_i \otimes 0}_{=0} = \sum_{i=0}^{n} e_i \otimes e_{n-i}.$$

(here, we have renamed the summation index i as k). Applying the map Δ to both sides of this equality, we obtain

$$\begin{aligned}
\Delta s_{(a+1,1^b)} &= \Delta\left(\sum_{k=0}^{b}(-1)^k h_{a+k+1}e_{b-k}\right) \\
&= \sum_{k=0}^{b}(-1)^k \underbrace{\Delta\left(h_{a+k+1}\right)}_{\substack{=\sum_{i\in\mathbb{N}} h_i\otimes h_{a+k+1-i} \\ \text{(by (13.90.16), applied to } n=a+k+1\text{)}}} \cdot \underbrace{\Delta\left(e_{b-k}\right)}_{\substack{=\sum_{i\in\mathbb{N}} e_i\otimes e_{b-k-i} \\ \text{(by (13.90.15), applied to } n=b-k\text{)}}} \\
&\qquad \left(\text{since } \Delta \text{ is a } \mathbf{k}\text{-algebra homomorphism}\right) \\
&= \sum_{k=0}^{b}(-1)^k \left(\sum_{i\in\mathbb{N}} h_i\otimes h_{a+k+1-i}\right)\left(\sum_{i\in\mathbb{N}} e_i\otimes e_{b-k-i}\right) \\
&= \sum_{k=0}^{b}(-1)^k \left(\sum_{i\in\mathbb{N}} h_i\otimes h_{a+k+1-i}\right)\left(\sum_{j\in\mathbb{N}} e_j\otimes e_{b-k-j}\right) \\
&\qquad \left(\text{here, we renamed the summation index } i \text{ as } j \text{ in the third sum}\right) \\
&= \sum_{k=0}^{b}(-1)^k \sum_{i\in\mathbb{N}}\sum_{j\in\mathbb{N}} \underbrace{\left(h_i\otimes h_{a+k+1-i}\right)\left(e_j\otimes e_{b-k-j}\right)}_{=h_ie_j\otimes h_{a+k+1-i}e_{b-k-j}} \\
&= \sum_{k=0}^{b}(-1)^k \sum_{i\in\mathbb{N}}\sum_{j\in\mathbb{N}} h_ie_j\otimes h_{a+k+1-i}e_{b-k-j} \\
&= \underbrace{\sum_{i\in\mathbb{N}}\sum_{j\in\mathbb{N}}}_{=\sum_{(i,j)\in\mathbb{N}^2}} \underbrace{h_ie_j}_{\substack{=e_jh_i \\ =\mathbf{s}(i,j-1)+\mathbf{s}(i-1,j) \\ \text{(by (13.90.5), applied to } j \text{ and } i \\ \text{instead of } n \text{ and } m\text{)}}} \otimes \underbrace{\left(\sum_{k=0}^{b}(-1)^k h_{a-i+k+1}e_{b-j-k}\right)}_{\substack{=\mathbf{s}(a-i,b-j) \\ \text{(by (13.90.10), applied to } a-i,\ b-j \text{ and } b \\ \text{instead of } a,\ b \text{ and } c \text{ (since } b\geq b-j\text{))}}} \\
&= \sum_{(i,j)\in\mathbb{N}^2}\left(\mathbf{s}\left(i,j-1\right)+\mathbf{s}\left(i-1,j\right)\right)\otimes\mathbf{s}\left(a-i,b-j\right). \qquad (13.90.17)
\end{aligned}$$

Now, applying (13.90.13) to $x = s_{(a+1,1^b)}$, we obtain

$$\begin{aligned}
&\Delta s_{(a+1,1^b)} - 1\otimes s_{(a+1,1^b)} - s_{(a+1,1^b)}\otimes 1 \\
&= \left(\overline{\mathrm{id}}\otimes\overline{\mathrm{id}}\right) \underbrace{\left(\Delta s_{(a+1,1^b)}\right)}_{\substack{=\sum_{(i,j)\in\mathbb{N}^2}(\mathbf{s}(i,j-1)+\mathbf{s}(i-1,j))\otimes\mathbf{s}(a-i,b-j) \\ \text{(by (13.90.17))}}} - \underbrace{\epsilon\left(s_{(a+1,1^b)}\right)}_{\substack{=0 \\ \text{(since } \left(a+1,1^b\right) \text{ is a} \\ \text{nonempty partition)}}} 1\otimes 1 \\
&= \left(\overline{\mathrm{id}}\otimes\overline{\mathrm{id}}\right)\left(\sum_{(i,j)\in\mathbb{N}^2}\left(\mathbf{s}\left(i,j-1\right)+\mathbf{s}\left(i-1,j\right)\right)\otimes\mathbf{s}\left(a-i,b-j\right)\right) - \underbrace{0\cdot 1\otimes 1}_{=0} \\
&= \left(\overline{\mathrm{id}}\otimes\overline{\mathrm{id}}\right)\left(\sum_{(i,j)\in\mathbb{N}^2}\left(\mathbf{s}\left(i,j-1\right)+\mathbf{s}\left(i-1,j\right)\right)\otimes\mathbf{s}\left(a-i,b-j\right)\right) \\
&= \sum_{(i,j)\in\mathbb{N}^2}\overline{\mathrm{id}}\left(\mathbf{s}\left(i,j-1\right)+\mathbf{s}\left(i-1,j\right)\right)\otimes\overline{\mathrm{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right) \\
&= \sum_{(i,j)\in\mathbb{N}^2}\overline{\mathrm{id}}\left(\mathbf{s}\left(i-1,j\right)\right)\otimes\overline{\mathrm{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right) + \sum_{(i,j)\in\mathbb{N}^2}\overline{\mathrm{id}}\left(\mathbf{s}\left(i,j-1\right)\right)\otimes\overline{\mathrm{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right). \qquad (13.90.18)
\end{aligned}$$

We can now observe that

$$\sum_{(i,j)\in\mathbb{N}^2} \overline{\operatorname{id}}\left(\mathbf{s}\left(i-1,j\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right) = \sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a-1;\\ d+f=b}} s_{(c+1,1^d)}\otimes s_{(e+1,1^f)}. \tag{13.90.19}$$

[717] Similarly,

$$\sum_{(i,j)\in\mathbb{N}^2} \overline{\operatorname{id}}\left(\mathbf{s}\left(i,j-1\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right) = \sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a;\\ d+f=b-1}} s_{(c+1,1^d)}\otimes s_{(e+1,1^f)}. \tag{13.90.21}$$

Now, (13.90.18) becomes

$$\begin{aligned}
&\Delta s_{(a+1,1^b)} - 1\otimes s_{(a+1,1^b)} - s_{(a+1,1^b)}\otimes 1\\
&= \underbrace{\sum_{(i,j)\in\mathbb{N}^2} \overline{\operatorname{id}}\left(\mathbf{s}\left(i-1,j\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right)}_{\substack{=\sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a-1;\\ d+f=b}} s_{(c+1,1^d)}\otimes s_{(e+1,1^f)}\\ \text{(by (13.90.19))}}} + \underbrace{\sum_{(i,j)\in\mathbb{N}^2} \overline{\operatorname{id}}\left(\mathbf{s}\left(i,j-1\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right)}_{\substack{=\sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a;\\ d+f=b-1}} s_{(c+1,1^d)}\otimes s_{(e+1,1^f)}\\ \text{(by (13.90.21))}}}\\
&= \sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a-1;\\ d+f=b}} s_{(c+1,1^d)}\otimes s_{(e+1,1^f)} + \sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a;\\ d+f=b-1}} s_{(c+1,1^d)}\otimes s_{(e+1,1^f)}.
\end{aligned}$$

Adding $1\otimes s_{(a+1,1^b)} + s_{(a+1,1^b)}\otimes 1$ to both sides of this equality, we obtain the claim of Exercise 2.9.14(d).

[717] *Proof of (13.90.19):* Let $\overline{\mathbb{N}} = \{-1,0,1,2,\ldots\} = \{-1\}\cup\mathbb{N}$. We have

$$\sum_{\substack{(c,d,e,f)\in\overline{\mathbb{N}}\times\mathbb{N}\times\mathbb{Z}\times\mathbb{Z};\\ c+e=a-1;\\ d+f=b}} \overline{\operatorname{id}}\left(\mathbf{s}\left(c,d\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(e,f\right)\right) = \sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a-1;\\ d+f=b}} \overline{\operatorname{id}}\left(\mathbf{s}\left(c,d\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(e,f\right)\right). \tag{13.90.20}$$

(In fact, the sum on the left hand side of (13.90.20) differs from that on the right hand side of (13.90.20) only by the presence of addends of the form $\overline{\operatorname{id}}\left(\mathbf{s}\left(c,d\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(e,f\right)\right)$ for certain quadruples $(c,d,e,f)\in\overline{\mathbb{N}}\times\mathbb{N}\times\mathbb{Z}\times\mathbb{Z}$ which don't belong to $\mathbb{N}^4$. But all such addends are 0 (as can be easily seen using (13.90.12)), and so the two sums have the same value, and (13.90.20) is proven.)

The map

$$\begin{aligned}
\mathbb{N}^2 &\to \left\{(c,d,e,f)\in\overline{\mathbb{N}}\times\mathbb{N}\times\mathbb{Z}\times\mathbb{Z} \mid c+e=a-1;\ d+f=b\right\},\\
(i,j) &\mapsto (i-1,j,a-i,b-j)
\end{aligned}$$

is a bijection. Hence, we can substitute $(i-1,j,a-i,b-j)$ for (c,d,e,f) in the sum $\sum_{\substack{(c,d,e,f)\in\overline{\mathbb{N}}\times\mathbb{N}\times\mathbb{Z}\times\mathbb{Z};\\ c+e=a-1;\\ d+f=b}} \overline{\operatorname{id}}\left(\mathbf{s}\left(c,d\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(e,f\right)\right)$, and thus obtain

$$\sum_{\substack{(c,d,e,f)\in\overline{\mathbb{N}}\times\mathbb{N}\times\mathbb{Z}\times\mathbb{Z};\\ c+e=a-1;\\ d+f=b}} \overline{\operatorname{id}}\left(\mathbf{s}\left(c,d\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(e,f\right)\right) = \sum_{(i,j)\in\mathbb{N}^2} \overline{\operatorname{id}}\left(\mathbf{s}\left(i-1,j\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right).$$

Comparing this with (13.90.20), we obtain

$$\begin{aligned}
&\sum_{(i,j)\in\mathbb{N}^2} \overline{\operatorname{id}}\left(\mathbf{s}\left(i-1,j\right)\right)\otimes\overline{\operatorname{id}}\left(\mathbf{s}\left(a-i,b-j\right)\right)\\
&= \sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a-1;\\ d+f=b}} \underbrace{\overline{\operatorname{id}}\left(\mathbf{s}\left(c,d\right)\right)}_{\substack{=s_{(c+1,1^d)}\\ \text{(by (13.90.11), applied to}\\ c\text{ and }d\text{ instead of }a\text{ and }b)}} \otimes \underbrace{\overline{\operatorname{id}}\left(\mathbf{s}\left(e,f\right)\right)}_{\substack{=s_{(e+1,1^f)}\\ \text{(by (13.90.11), applied to}\\ e\text{ and }f\text{ instead of }a\text{ and }b)}}\\
&= \sum_{\substack{(c,d,e,f)\in\mathbb{N}^4;\\ c+e=a-1;\\ d+f=b}} s_{(c+1,1^d)}\otimes s_{(e+1,1^f)}.
\end{aligned}$$

This proves (13.90.19).

Remark: In our above solution, we have first proved (13.90.5) and then used it to derive (13.90.8). There is also an alternative way to prove these two identities, which proceeds the other way round. The main idea is to obtain (13.90.8) by applying Exercise 2.9.1(b) to $\lambda = (1^b)$ and $m = a + 1$. (This works in the case of $a \in \mathbb{N}$ and $b \in \mathbb{N}$ only. The remaining cases, however, are easy to either check directly or reduce to (2.4.4).) Once this is done, (13.90.5) can be verified by rewriting both $\mathbf{s}(m, n-1)$ and $\mathbf{s}(m-1, n)$ using (13.90.8).

13.91. **Solution to Exercise 2.9.15.** *Solution to Exercise 2.9.15.* Consider the partition $(m^k) = \left(\underbrace{m, m, \ldots, m}_{k \text{ times}}\right)$.

(a) The fact that $\lambda^\vee$ and $\mu^\vee$ are partitions is easy to check. It remains to show that $s_{\lambda/\mu} = s_{\mu^\vee/\lambda^\vee}$.

It is easy to show that if $\mu \subseteq \lambda$ does not hold, then $\lambda^\vee \subseteq \mu^\vee$ does not hold either (because if some positive integer i fails to satisfy $\mu_i \leq \lambda_i$, then this i belongs to $\{1, 2, \ldots, k\}$ and fails to satisfy $m - \lambda_i \leq m - \mu_i$ as well). Hence, if $\mu \subseteq \lambda$ does not hold, then both $s_{\lambda/\mu}$ and $s_{\mu^\vee/\lambda^\vee}$ are 0, and therefore the equality $s_{\lambda/\mu} = s_{\mu^\vee/\lambda^\vee}$ is obvious. Hence, for the rest of the proof of $s_{\lambda/\mu} = s_{\mu^\vee/\lambda^\vee}$, we WLOG assume that $\mu \subseteq \lambda$ does hold. Then, it is easy to see that $\lambda^\vee \subseteq \mu^\vee$ holds, too.

Now, let Z denote the 180° rotation around the center of the Ferrers diagram of (m^k). Let $Y(\rho)$ denote the Ferrers diagram of ρ whenever ρ is a partition or a skew partition. It is straightforward to see that $Z\left(Y\left((m^k)\right) \setminus Y(\mu)\right) = Y(\mu^\vee)$ and $Z\left(Y\left((m^k)\right) \setminus Y(\lambda)\right) = Y(\lambda^\vee)$. Now,

$$Y(\mu^\vee/\lambda^\vee) = \underbrace{Y(\mu^\vee)}_{=Z(Y((m^k))\setminus Y(\mu))} \setminus \underbrace{Y(\lambda^\vee)}_{=Z(Y((m^k))\setminus Y(\lambda))} = Z\left(Y\left((m^k)\right) \setminus Y(\mu)\right) \setminus Z\left(Y\left((m^k)\right) \setminus Y(\lambda)\right)$$

$$= Z\left(\underbrace{\left(Y\left((m^k)\right) \setminus Y(\mu)\right) \setminus \left(Y\left((m^k)\right) \setminus Y(\lambda)\right)}_{\substack{=Y(\lambda)\setminus Y(\mu) \\ \text{(since one can easily see that both } Y(\lambda) \text{ and } Y(\mu) \\ \text{are subsets of } Y((m^k)))}}\right)$$

$$= Z\left(\underbrace{Y(\lambda) \setminus Y(\mu)}_{=Y(\lambda/\mu)}\right) = Z\left(Y(\lambda/\mu)\right).$$

Hence, the skew Ferrers diagram $\mu^\vee/\lambda^\vee$ can be obtained from the skew Ferrers diagram λ/μ by a 180° rotation (namely, by the 180° rotation Z). Thus, Exercise 2.3.4(b) (applied to $\lambda' = \mu^\vee$ and $\mu' = \lambda^\vee$) yields $s_{\lambda/\mu} = s_{\mu^\vee/\lambda^\vee}$. This completes the solution of Exercise 2.9.15(a).

(b) According to Remark 2.5.9, we have $s_{\lambda/\mu} = \sum_\nu c^\lambda_{\mu,\nu} s_\nu$, where the sum ranges over all partitions ν. In other words, we have

$$s_{\lambda/\mu} = \sum_{\nu \in \mathrm{Par}} c^\lambda_{\mu,\nu} s_\nu. \tag{13.91.1}$$

Exercise 2.9.15(b) yields that $\lambda^\vee$ and $\mu^\vee$ are partitions, and that $s_{\lambda/\mu} = s_{\mu^\vee/\lambda^\vee}$. Applying (13.91.1) to $\mu^\vee$ and $\lambda^\vee$ instead of λ and μ, we obtain

$$s_{\mu^\vee/\lambda^\vee} = \sum_{\nu \in \mathrm{Par}} c^{\mu^\vee}_{\lambda^\vee,\nu} s_\nu.$$

Now, (13.91.1) yields

$$\sum_{\nu \in \mathrm{Par}} c^\lambda_{\mu,\nu} s_\nu = s_{\lambda/\mu} = s_{\mu^\vee/\lambda^\vee} = \sum_{\nu \in \mathrm{Par}} c^{\mu^\vee}_{\lambda^\vee,\nu} s_\nu.$$

Comparing coefficients before s_ν in this equality, we conclude that $c^\lambda_{\mu,\nu} = c^{\mu^\vee}_{\lambda^\vee,\nu}$ for every $\nu \in \mathrm{Par}$ (since $(s_\nu)_{\nu \in \mathrm{Par}}$ is a basis of the $\mathbf{k}$-module Λ). This solves Exercise 2.9.15(b).

(c) Exercise 2.9.15(a) (applied to ν instead of μ) yields that $\lambda^\vee$ and $\nu^\vee$ are partitions and that $s_{\lambda/\nu} = s_{\nu^\vee/\lambda^\vee}$.

From (2.5.8), we obtain

$$\begin{aligned} c^{\lambda}_{\mu,\nu} = c^{\lambda}_{\nu,\mu} = c^{\nu^\vee}_{\lambda^\vee,\mu} \qquad & \text{(by Exercise 2.9.15(b) (applied to } \nu \text{ and } \mu \text{ instead of } \mu \text{ and } \nu\text{))} \\ = c^{\nu^\vee}_{\mu,\lambda^\vee} \qquad & \text{(by (2.5.8) (applied to } \nu^\vee\text{, } \lambda^\vee \text{ and } \mu \text{ instead of } \lambda\text{, } \mu \text{ and } \nu\text{))} . \end{aligned}$$

On the other hand, Exercise 2.9.15(b) yields $c^{\lambda}_{\mu,\nu} = c^{\mu^\vee}_{\lambda^\vee,\nu} = c^{\mu^\vee}_{\nu,\lambda^\vee}$ (by (2.5.8) (applied to $\mu^\vee$, $\lambda^\vee$ and ν instead of λ, μ and ν)). Thus, $c^{\mu^\vee}_{\nu,\lambda^\vee} = c^{\mu^\vee}_{\lambda^\vee,\nu} = c^{\lambda}_{\mu,\nu} = c^{\lambda}_{\nu,\mu} = c^{\nu^\vee}_{\lambda^\vee,\mu} = c^{\nu^\vee}_{\mu,\lambda^\vee}$. This solves Exercise 2.9.15(c).

(d) *First solution to Exercise 2.9.15(d):* Notice that $\lambda^\vee = (m - \lambda_k, m - \lambda_{k-1}, \ldots, m - \lambda_1)$. Thus, $\ell(\lambda^\vee) \leq k$.

Let $n = k$. We shall use the notations of Section 2.6; in particular, we set $\mathbf{x} = (x_1, x_2, \ldots, x_n)$ and $\rho = (n-1, n-2, \ldots, 2, 1, 0)$. Clearly, $\mathbf{x} = (x_1, x_2, \ldots, x_n) = (x_1, x_2, \ldots, x_k)$ (since $n = k$). Notice that $\ell(\lambda) \leq k = n$. Hence, we can regard λ as an element of $\mathbb{N}^n$; therefore, $\lambda + \rho$ is a well-defined element of $\mathbb{N}^n$, and the alternant $a_{\lambda+\rho}$ is well-defined. Corollary 2.6.7 yields that $s_\lambda(\mathbf{x}) = \dfrac{a_{\lambda+\rho}}{a_\rho}$, so that

$$a_\rho \cdot s_\lambda(\mathbf{x}) = a_{\lambda+\rho}. \tag{13.91.2}$$

Applying this equality to $\lambda^\vee$ instead of λ, we obtain

$$a_\rho \cdot s_{\lambda^\vee}(\mathbf{x}) = a_{\lambda^\vee+\rho} \tag{13.91.3}$$

(since $\lambda^\vee$ is also a partition satisfying $\ell(\lambda^\vee) \leq k = n$).

Substituting the variables $x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}$ for $x_1, x_2, \ldots, x_n$ in the equality (13.91.2), we obtain

$$a_\rho\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \cdot s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) = a_{\lambda+\rho}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right). \tag{13.91.4}$$

Let $w_\circ : \{1, 2, \ldots, n\} \to \{1, 2, \ldots, n\}$ be the map which sends every $i \in \{1, 2, \ldots, n\}$ to $n + 1 - i$. Then, $w_\circ$ is a permutation of $\{1, 2, \ldots, n\}$, thus an element of $\mathfrak{S}_n$. For every $i \in \{1, 2, \ldots, n\}$, we have

$$(w \circ w_\circ)(i) = w(n + 1 - i). \tag{13.91.5}$$

The map $\mathfrak{S}_n \to \mathfrak{S}_n,\ w \mapsto w \circ w_\circ$ is a bijection (since $\mathfrak{S}_n$ is a group, and since $w_\circ \in \mathfrak{S}_n$).

But every $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_n) \in \mathbb{N}^n$ satisfies

$$\begin{aligned} a_\alpha &= \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \underbrace{w(\mathbf{x}^\alpha)}_{\substack{= \prod_{i=1}^n x_{w(i)}^{\alpha_i} \\ \text{(by the definition of } w(\mathbf{x}^\alpha))}} \qquad \text{(by the definition of } a_\alpha) \\ &= \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^n x_{w(i)}^{\alpha_i}. \end{aligned} \tag{13.91.6}$$

But $\lambda = (\lambda_1, \lambda_2, \lambda_3, \ldots)$, thus $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_n)$ (since $\ell(\lambda) \leq k = n$). Hence,

$$\begin{aligned} \underbrace{\lambda}_{=(\lambda_1, \lambda_2, \ldots, \lambda_n)} + \underbrace{\rho}_{\substack{=(n-1, n-2, \ldots, 2, 1, 0) \\ =(n-1, n-2, \ldots, n-n)}} &= (\lambda_1, \lambda_2, \ldots, \lambda_n) + (n-1, n-2, \ldots, n-n) \\ &= (\lambda_1 + n - 1, \lambda_2 + n - 2, \ldots, \lambda_n + n - n). \end{aligned}$$

Thus, (13.91.6) (applied to $\lambda + \rho$ and $(\lambda_1 + n - 1, \lambda_2 + n - 2, \ldots, \lambda_n + n - n)$ instead of α and $(\alpha_1, \alpha_2, \ldots, \alpha_n)$) yields

$$a_{\lambda+\rho} = \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^n x_{w(i)}^{\lambda_i + n - i}. \tag{13.91.7}$$

Substituting x_1^{-1}, x_2^{-1}, …, x_n^{-1} for x_1, x_2, …, x_n on both sides of this equality, we obtain

$$\begin{aligned}
& a_{\lambda+\rho}\left(x_1^{-1},x_2^{-1},\ldots,x_n^{-1}\right) \\
&= \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} \underbrace{\left(x_{w(i)}^{-1}\right)^{\lambda_i+n-i}}_{=x_{w(i)}^{-(\lambda_i+n-i)}} = \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \underbrace{\prod_{i=1}^{n} x_{w(i)}^{-(\lambda_i+n-i)}}_{\substack{=\prod_{i=1}^{n} x_{w(n+1-i)}^{-(\lambda_{n+1-i}+n-(n+1-i))} \\ \text{(here, we have substituted} \\ n+1-i \text{ for } i \text{ in the product)}}} \\
&= \sum_{w\in\mathfrak{S}_n} \underbrace{\operatorname{sgn}(w)}_{=\frac{1}{\operatorname{sgn}(w_\circ)}\operatorname{sgn}(w)\operatorname{sgn}(w_\circ)} \prod_{i=1}^{n} \underbrace{x_{w(n+1-i)}^{-(\lambda_{n+1-i}+n-(n+1-i))}}_{\substack{=x_{w(n+1-i)}^{-(\lambda_{n+1-i}+i-1)} \\ (\text{since } n-(n+1-i)=i-1)}} \\
&= \sum_{w\in\mathfrak{S}_n} \frac{1}{\operatorname{sgn}(w_\circ)} \underbrace{\operatorname{sgn}(w)\operatorname{sgn}(w_\circ)}_{=\operatorname{sgn}(w\circ w_\circ)} \prod_{i=1}^{n} \underbrace{x_{w(n+1-i)}^{-(\lambda_{n+1-i}+i-1)}}_{\substack{=x_{(w\circ w_\circ)(i)}^{-(\lambda_{n+1-i}+i-1)} \\ (\text{since } w(n+1-i)=(w\circ w_\circ)(i) \\ (\text{by } (13.91.5)))}} \\
&= \sum_{w\in\mathfrak{S}_n} \frac{1}{\operatorname{sgn}(w_\circ)} \operatorname{sgn}(w\circ w_\circ) \prod_{i=1}^{n} x_{(w\circ w_\circ)(i)}^{-(\lambda_{n+1-i}+i-1)} = \sum_{w\in\mathfrak{S}_n} \frac{1}{\operatorname{sgn}(w_\circ)} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{-(\lambda_{n+1-i}+i-1)} \\
&\qquad \left(\begin{array}{c} \text{here, we substituted } w \text{ for } w\circ w_\circ \text{ in the sum} \\ \text{(since the map } \mathfrak{S}_n\to\mathfrak{S}_n,\ w\mapsto w\circ w_\circ \text{ is a bijection)} \end{array}\right) \\
&= \frac{1}{\operatorname{sgn}(w_\circ)} \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{-(\lambda_{n+1-i}+i-1)}.
\end{aligned}$$

Multiplying both sides of this equality by $\operatorname{sgn}(w_\circ)$, we obtain

$$\operatorname{sgn}(w_\circ)\cdot a_{\lambda+\rho}\left(x_1^{-1},x_2^{-1},\ldots,x_n^{-1}\right) = \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{-(\lambda_{n+1-i}+i-1)}. \tag{13.91.8}$$

But $\lambda^\vee = (m-\lambda_k, m-\lambda_{k-1}, \ldots, m-\lambda_1) = (m-\lambda_n, m-\lambda_{n-1}, \ldots, m-\lambda_1)$ (since $k=n$), so that

$$\begin{aligned}
& \underbrace{\lambda^\vee}_{\substack{=(m-\lambda_n,m-\lambda_{n-1},\ldots,m-\lambda_1) \\ =\left(m-\lambda_{(n+1)-1},m-\lambda_{(n+1)-2},\ldots,m-\lambda_{(n+1)-n}\right)}} + \underbrace{\rho}_{\substack{=(n-1,n-2,\ldots,2,1,0) \\ =(n-1,n-2,\ldots,n-n)}} \\
&= \left(m-\lambda_{(n+1)-1}, m-\lambda_{(n+1)-2}, \ldots, m-\lambda_{(n+1)-n}\right) + (n-1, n-2, \ldots, n-n) \\
&= \left(\left(m-\lambda_{(n+1)-1}\right)+(n-1), \left(m-\lambda_{(n+1)-2}\right)+(n-2), \ldots, \left(m-\lambda_{(n+1)-n}\right)+(n-n)\right).
\end{aligned}$$

Hence, (13.91.6) (applied to $\lambda^\vee+\rho$ and $\left(\left(m-\lambda_{(n+1)-1}\right)+(n-1), \left(m-\lambda_{(n+1)-2}\right)+(n-2), \ldots, \left(m-\lambda_{(n+1)-n}\right)+(n-n)\right)$ instead of α and

$(\alpha_1, \alpha_2, \ldots, \alpha_n))$ yields

$$\begin{aligned}
a_{\lambda^\vee+\rho} &= \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} \underbrace{x_{w(i)}^{\left(m-\lambda_{(n+1)-i}\right)+(n-i)}}_{\substack{= x_{w(i)}^{-\left(\lambda_{n+1-i}+i-1\right)+(n+m-1)} \\ = x_{w(i)}^{-\left(\lambda_{n+1-i}+i-1\right)} x_{w(i)}^{n+m-1}}} \\
&= \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \underbrace{\prod_{i=1}^{n} \left(x_{w(i)}^{-\left(\lambda_{n+1-i}+i-1\right)} x_{w(i)}^{n+m-1} \right)}_{=\left(\prod_{i=1}^{n} x_{w(i)}^{-\left(\lambda_{n+1-i}+i-1\right)}\right)\left(\prod_{i=1}^{n} x_{w(i)}^{n+m-1}\right)} \\
&= \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \left(\prod_{i=1}^{n} x_{w(i)}^{-\left(\lambda_{n+1-i}+i-1\right)} \right) \underbrace{\left(\prod_{i=1}^{n} x_{w(i)}^{n+m-1} \right)}_{\substack{=\prod_{i=1}^{n} x_i^{n+m-1} \\ \text{(here, we have substituted } i \text{ for } w(i) \text{ in the product} \\ \text{(since } w \text{ is a permutation of } \{1,2,\ldots,n\}))}} \\
&= \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \left(\prod_{i=1}^{n} x_{w(i)}^{-\left(\lambda_{n+1-i}+i-1\right)} \right) \left(\prod_{i=1}^{n} x_i^{n+m-1} \right) \\
&= \underbrace{\left(\prod_{i=1}^{n} x_i^{n+m-1} \right)}_{=\left(\prod_{i=1}^{n} x_i\right)^{n+m-1}} \underbrace{\sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{-\left(\lambda_{n+1-i}+i-1\right)}}_{\substack{=\operatorname{sgn}(w_\circ) \cdot a_{\lambda+\rho}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \\ \text{(by (13.91.8))}}} \\
&= \left(\prod_{i=1}^{n} x_i \right)^{n+m-1} \cdot \operatorname{sgn}(w_\circ) \cdot a_{\lambda+\rho}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right). \qquad (13.91.9)
\end{aligned}$$

Finally, $\rho = (n-1, n-2, \ldots, 2, 1, 0) = (n-1, n-2, \ldots, n-n)$. Thus, (13.91.6) (applied to ρ and $(n-1, n-2, \ldots, n-n)$ instead of α and $(\alpha_1, \alpha_2, \ldots, \alpha_n))$ yields

$$a_\rho = \sum_{w \in \mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{n-i}. \qquad (13.91.10)$$

Substituting x_1^{-1}, x_2^{-1}, …, x_n^{-1} for x_1, x_2, …, x_n on both sides of this equality, we obtain

$$\begin{aligned}
&a_\rho\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \\
&= \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} \underbrace{\left(x_{w(i)}^{-1}\right)^{n-i}}_{=x_{w(i)}^{-(n-i)}=x_{w(i)}^{i-n}} = \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \underbrace{\prod_{i=1}^{n} x_{w(i)}^{i-n}}_{\substack{=\prod_{i=1}^{n} x_{w(n+1-i)}^{(n+1-i)-n} \\ \text{(here, we have substituted} \\ n+1-i \text{ for } i \text{ in the product)}}} \\
&= \sum_{w\in\mathfrak{S}_n} \underbrace{\operatorname{sgn}(w)}_{=\frac{1}{\operatorname{sgn}(w_\circ)} \operatorname{sgn}(w)\operatorname{sgn}(w_\circ)} \prod_{i=1}^{n} \underbrace{x_{w(n+1-i)}^{(n+1-i)-n}}_{=x_{w(n+1-i)}^{-i+1}} \\
&= \sum_{w\in\mathfrak{S}_n} \frac{1}{\operatorname{sgn}(w_\circ)} \underbrace{\operatorname{sgn}(w)\operatorname{sgn}(w_\circ)}_{=\operatorname{sgn}(w\circ w_\circ)} \prod_{i=1}^{n} \underbrace{x_{w(n+1-i)}^{-i+1}}_{\substack{=x_{(w\circ w_\circ)(i)}^{-i+1} \\ \text{(since } w(n+1-i)=(w\circ w_\circ)(i) \\ \text{(by (13.91.5)))}}} \\
&= \sum_{w\in\mathfrak{S}_n} \frac{1}{\operatorname{sgn}(w_\circ)} \operatorname{sgn}(w\circ w_\circ) \prod_{i=1}^{n} x_{(w\circ w_\circ)(i)}^{-i+1} = \sum_{w\in\mathfrak{S}_n} \frac{1}{\operatorname{sgn}(w_\circ)} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{-i+1} \\
&\qquad \left(\begin{array}{c} \text{here, we substituted } w \text{ for } w\circ w_\circ \text{ in the sum} \\ \text{(since the map } \mathfrak{S}_n \to \mathfrak{S}_n,\ w\mapsto w\circ w_\circ \text{ is a bijection)} \end{array}\right) \\
&= \frac{1}{\operatorname{sgn}(w_\circ)} \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} \underbrace{x_{w(i)}^{-i+1}}_{\substack{=x_{w(i)}^{(n-i)+(1-n)} \\ =x_{w(i)}^{n-i} x_{w(i)}^{1-n}}} = \frac{1}{\operatorname{sgn}(w_\circ)} \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \underbrace{\prod_{i=1}^{n} \left(x_{w(i)}^{n-i} x_{w(i)}^{1-n}\right)}_{=\left(\prod_{i=1}^{n} x_{w(i)}^{n-i}\right)\left(\prod_{i=1}^{n} x_{w(i)}^{1-n}\right)} \\
&= \frac{1}{\operatorname{sgn}(w_\circ)} \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \left(\prod_{i=1}^{n} x_{w(i)}^{n-i}\right) \underbrace{\left(\prod_{i=1}^{n} x_{w(i)}^{1-n}\right)}_{\substack{=\prod_{i=1}^{n} x_i^{1-n} \\ \text{(here, we have substituted } i \text{ for } w(i) \text{ in the product} \\ \text{(since } w \text{ is a permutation of } \{1,2,\ldots,n\}))}} \\
&= \frac{1}{\operatorname{sgn}(w_\circ)} \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \left(\prod_{i=1}^{n} x_{w(i)}^{n-i}\right) \left(\prod_{i=1}^{n} x_i^{1-n}\right) = \frac{1}{\operatorname{sgn}(w_\circ)} \underbrace{\left(\prod_{i=1}^{n} x_i^{1-n}\right)}_{=\left(\prod_{i=1}^{n} x_i\right)^{1-n}} \underbrace{\sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{n-i}}_{\substack{=a_\rho \\ \text{(by (13.91.10))}}} \\
&= \frac{1}{\operatorname{sgn}(w_\circ)} \left(\prod_{i=1}^{n} x_i\right)^{1-n} a_\rho.
\end{aligned}$$

Multiplying both sides of this equality by $\operatorname{sgn}(w_\circ)$, we obtain

$$\operatorname{sgn}(w_\circ) \cdot a_\rho\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) = \left(\prod_{i=1}^{n} x_i\right)^{1-n} a_\rho. \tag{13.91.11}$$

Now, (13.91.3) becomes

$$\begin{aligned}
a_{\rho} \cdot s_{\lambda^{\vee}}\left(\mathbf{x}\right) &= a_{\lambda^{\vee}+\rho} \\
&= \left(\prod_{i=1}^{n} x_i\right)^{n+m-1} \cdot \operatorname{sgn}\left(w_{\circ}\right) \cdot \underbrace{a_{\lambda+\rho}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right)}_{\substack{=a_{\rho}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \cdot s_{\lambda}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \\ \text{(by (13.91.4))}}} \\
&\qquad \text{(by (13.91.9))} \\
&= \left(\prod_{i=1}^{n} x_i\right)^{n+m-1} \cdot \underbrace{\operatorname{sgn}\left(w_{\circ}\right) \cdot a_{\rho}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right)}_{\substack{=\left(\prod_{i=1}^{n} x_i\right)^{1-n} a_{\rho} \\ \text{(by (13.91.11))}}} \cdot s_{\lambda}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \\
&= \underbrace{\left(\prod_{i=1}^{n} x_i\right)^{n+m-1} \cdot \left(\prod_{i=1}^{n} x_i\right)^{1-n}}_{=\left(\prod_{i=1}^{n} x_i\right)^{(n+m-1)+(1-n)} = \left(\prod_{i=1}^{n} x_i\right)^{m}} a_{\rho} \cdot s_{\lambda}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \\
&= \left(\underbrace{\prod_{i=1}^{n} x_i}_{=x_1 x_2 \cdots x_n}\right)^{m} a_{\rho} \cdot s_{\lambda}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \\
&= \left(x_1 x_2 \cdots x_n\right)^{m} a_{\rho} \cdot s_{\lambda}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) \\
&= a_{\rho} \cdot \left(x_1 x_2 \cdots x_n\right)^{m} \cdot s_{\lambda}\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) . \qquad (13.91.12)
\end{aligned}$$

But[718]

$$a_{\rho} \text{ is a non-zero-divisor in the ring } \mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right] . \tag{13.91.13}$$

[718] In the following, a *non-zero-divisor* in a commutative ring B means an element $b \in B$ such that every element $c \in B$ satisfying $bc = 0$ must satisfy $c = 0$.

[719] Hence, we can cancel the factor a_ρ from the equality (13.91.12). As a result, we obtain $s_{\lambda^\vee}(\mathbf{x}) = (x_1 x_2 \cdots x_n)^m \cdot s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right)$. Compared with $s_{\lambda^\vee}(\mathbf{x}) = s_{\lambda^\vee}(x_1, x_2, \ldots, x_k)$ (since $\mathbf{x} = (x_1, x_2, \ldots, x_k)$), this yields

$$s_{\lambda^\vee}(x_1, x_2, \ldots, x_k) = (x_1 x_2 \cdots x_n)^m \cdot s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right) = (x_1 x_2 \cdots x_k)^m \cdot s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right)$$

(since $n = k$). This solves Exercise 2.9.15(d).

Second solution to Exercise 2.9.15(d) (sketched): Let us give a more combinatorial solution now. In the following, if α is a partition, then an (α, k)*-CST* will mean a column-strict tableau T of shape α such that all entries of T belong to $\{1, 2, \ldots, k\}$.

We have

$$\underbrace{s_{\lambda^\vee}}_{= s_{\lambda^\vee/\varnothing}}(x_1, x_2, \ldots, x_k) = s_{\lambda^\vee/\varnothing}(x_1, x_2, \ldots, x_k) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda^\vee/\varnothing; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \mathbf{x}^{\operatorname{cont}(T)}$$

(by Exercise 2.3.8(a), applied to k, $\lambda^\vee$ and $\varnothing$ instead of n, λ and μ). This rewrites as

$$s_{\lambda^\vee}(x_1, x_2, \ldots, x_k) = \sum_{T \text{ is a } (\lambda^\vee, k)\text{-CST}} \mathbf{x}^{\operatorname{cont}(T)} \qquad (13.91.14)$$

(because the column-strict tableaux T of shape $\lambda^\vee/\varnothing$ such that all entries of T belong to $\{1, 2, \ldots, k\}$ are precisely the $(\lambda^\vee, k)$-CSTs).

On the other hand,

$$\underbrace{s_{\lambda}}_{= s_{\lambda/\varnothing}}(x_1, x_2, \ldots, x_k) = s_{\lambda/\varnothing}(x_1, x_2, \ldots, x_k) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\varnothing; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \mathbf{x}^{\operatorname{cont}(T)}$$

[719] *Proof.* We know (from a footnote in Corollary 2.6.7) that a_ρ is not a zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$. In other words, a_ρ is a non-zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$.

Now, let b be any element of the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$ such that b is a non-zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$. We shall show that b is a non-zero-divisor in the ring $\mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$ as well.

Indeed, let $c \in \mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$ be such that $bc = 0$. It is known that every element of $\mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$ has the form $\dfrac{p}{x_1^{g_1} x_2^{g_2} \cdots x_n^{g_n}}$ for some $p \in \mathbf{k}[x_1, x_2, \ldots, x_n]$ and some $(g_1, g_2, \ldots, g_n) \in \mathbb{N}^n$. So let us write c in this form, and consider the corresponding p and $(g_1, g_2, \ldots, g_n)$. We thus have $c = \dfrac{p}{x_1^{g_1} x_2^{g_2} \cdots x_n^{g_n}}$. Now, $bc = 0$. This rewrites as $b \cdot \dfrac{p}{x_1^{g_1} x_2^{g_2} \cdots x_n^{g_n}} = 0$ (since $c = \dfrac{p}{x_1^{g_1} x_2^{g_2} \cdots x_n^{g_n}}$). Multiplying both sides of this equality by $x_1^{g_1} x_2^{g_2} \cdots x_n^{g_n}$, we obtain $bp = 0$. This equality holds in the ring $\mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$, and thus also in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$ (since $\mathbf{k}[x_1, x_2, \ldots, x_n]$ is a subring of $\mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$). Thus, $p = 0$ (since b is a non-zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$, and since $p \in \mathbf{k}[x_1, x_2, \ldots, x_n]$). Hence,

$$c = \frac{p}{x_1^{g_1} x_2^{g_2} \cdots x_n^{g_n}} = \frac{0}{x_1^{g_1} x_2^{g_2} \cdots x_n^{g_n}} \qquad (\text{since } p = 0)$$
$$= 0.$$

Now, let us forget that we fixed c. We thus have proven that every element $c \in \mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$ satisfying $bc = 0$ must satisfy $c = 0$. In other words, b is a non-zero-divisor in the ring $\mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$.

Now, let us forget that we fixed b. We thus have proven that if b is any element of the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$ such that b is a non-zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$, then b is a non-zero-divisor in the ring $\mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$ as well. Applying this to $b = a_\rho$, we conclude that a_ρ is a non-zero-divisor in the ring $\mathbf{k}\left[x_1, x_2, \ldots, x_n, x_1^{-1}, x_2^{-1}, \ldots, x_n^{-1}\right]$ (since we know that a_ρ is a non-zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$). This proves (13.91.13).

(by Exercise 2.3.8(a), applied to k and $\varnothing$ instead of n and μ). Substituting x_1^{-1}, x_2^{-1}, ..., x_k^{-1} for x_1, x_2, ..., x_k on both sides of this equality, we obtain

$$s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda/\varnothing; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)}, \tag{13.91.15}$$

where $\left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)}$ is defined as $\prod_{i\geq 1}\left(x_i^{-1}\right)^{\left|T^{-1}(i)\right|}$ for any column-strict tableau T. The equality (13.91.15) rewrites as

$$s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) = \sum_{T \text{ is a } (\lambda,k)\text{-CST}} \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)}$$

(since the column-strict tableaux T of shape $\lambda/\varnothing$ such that all entries of T belong to $\{1, 2, \ldots, k\}$ are precisely the (λ, k)-CSTs). Hence,

$$\begin{aligned} (x_1x_2\cdots x_k)^m \cdot s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) &= (x_1x_2\cdots x_k)^m \cdot \sum_{T \text{ is a } (\lambda,k)\text{-CST}} \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)} \\ &= \sum_{T \text{ is a } (\lambda,k)\text{-CST}} (x_1x_2\cdots x_k)^m \cdot \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)}. \end{aligned} \tag{13.91.16}$$

We need to prove that

$$s_{\lambda^\vee}(x_1, x_2, \ldots, x_k) = (x_1x_2\cdots x_k)^m \cdot s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right).$$

Due to (13.91.14) and (13.91.16), this rewrites as

$$\sum_{T \text{ is a } (\lambda^\vee,k)\text{-CST}} \mathbf{x}^{\operatorname{cont}(T)} = \sum_{T \text{ is a } (\lambda,k)\text{-CST}} (x_1x_2\cdots x_k)^m \cdot \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)}. \tag{13.91.17}$$

So it remains to prove (13.91.17).

In order to prove (13.91.17), it is clearly sufficient to construct a bijection

$$\Omega : (\text{the set of all } (\lambda, k)\text{-CSTs}) \to (\text{the set of all } (\lambda^\vee, k)\text{-CSTs})$$

with the property that every (λ, k)-CST T satisfies

$$\mathbf{x}^{\operatorname{cont}(\Omega(T))} = (x_1x_2\cdots x_k)^m \cdot \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)}. \tag{13.91.18}$$

Let us construct such a Ω now. We begin by doing some elementary combinatorics.

We define a relation $\leq_\#$ on the set of all subsets of $\{1, 2, \ldots, k\}$ as follows:

Definition 13.91.1. Let k be a nonnegative integer. Let $[k] = \{1, 2, \ldots, k\}$. Let I and J be two subsets of $[k]$. We say that $I \leq_\# J$ if the following two properties hold:

– We have $|I| \geq |J|$.

– For every $r \in \{1, 2, \ldots, |J|\}$, the r-th smallest element of I is $\leq$ to the r-th smallest element of J.

We notice that this relation $\leq_\#$ is the less-or-equal relation of a partial order (as follows easily from the definition); but we will not have any use for this fact. Instead, we need a symmetry property:

Proposition 13.91.2. *Let k be a nonnegative integer. Let $[k] = \{1, 2, \ldots, k\}$. Let I and J be two subsets of $[k]$.*

(a) *We have $I \leq_\# J$ if and only if $[k] \setminus J \leq_\# [k] \setminus I$.*

(b) *For every $\ell \in [k]$ and $S \subset [k]$, let $\alpha_S(\ell)$ denote the number $|\{s \in S \mid s \leq \ell\}|$. Then,*

$$I \leq_\# J \text{ holds if and only if every } \ell \in [k] \text{ satisfies } \alpha_I(\ell) \geq \alpha_J(\ell). \tag{13.91.19}$$

Proof of Proposition 13.91.2. (b) *Proof of (13.91.19):* $\Longrightarrow$: Assume that $I \leq_\# J$. In other words, the following two properties hold:

Property α: We have $|I| \geq |J|$.

Property β: For every $r \in \{1, 2, \ldots, |J|\}$, the r-th smallest element of I is $\leq$ to the r-th smallest element of J.

Now, let $\ell \in [k]$. Then, we need to show that $\alpha_I(\ell) \geq \alpha_J(\ell)$. Since this is obvious if $\alpha_J(\ell) = 0$ (because $\alpha_I(\ell) \geq 0$), we can WLOG assume that $\alpha_J(\ell) \neq 0$. Assume this. Thus, $\alpha_J(\ell) \geq 1$. Also, $\alpha_J(\ell) = \left|\underbrace{\{s \in J \mid s \leq \ell\}}_{\subset J}\right| \leq |J| \leq |I|$ (since $|I| \geq |J|$). Hence, both the $\alpha_J(\ell)$-th smallest element of J and the $\alpha_J(\ell)$-th smallest element of I are well-defined.

Since $\alpha_J(\ell) = |\{s \in J \mid s \leq \ell\}|$, we know that the elements of J which are $\leq \ell$ are precisely the $\alpha_J(\ell)$ smallest elements of J. Thus,

$$(\text{the } \alpha_J(\ell)\text{-th smallest element of } J) = (\text{the largest element of } J \text{ which is } \leq \ell).$$

But by Property β (applied to $r = \alpha_J(\ell)$), we have

$$\begin{aligned}(\text{the } \alpha_J(\ell)\text{-th smallest element of } I) &\leq (\text{the } \alpha_J(\ell)\text{-th smallest element of } J) \\ &= (\text{the largest element of } J \text{ which is } \leq \ell) \leq \ell.\end{aligned}$$

Hence, there are at least $\alpha_J(\ell)$ elements of I which are $\leq \ell$ (namely, the $\alpha_J(\ell)$ smallest ones). In other words, $|\{s \in I \mid s \leq \ell\}| \geq \alpha_J(\ell)$. Now, $\alpha_I(\ell) = |\{s \in I \mid s \leq \ell\}| \geq \alpha_J(\ell)$. We thus have proven the $\Longrightarrow$ direction of (13.91.19).

$\Longleftarrow$: Assume that every $\ell \in [k]$ satisfies $\alpha_I(\ell) \geq \alpha_J(\ell)$. We need to prove that $I \leq_{\#} J$. In other words, we need to prove that the following two properties hold:

Property α: We have $|I| \geq |J|$.

Property β: For every $r \in \{1, 2, \ldots, |J|\}$, the r-th smallest element of I is $\leq$ to the r-th smallest element of J.

First of all, $\{s \in I \mid s \leq k\} = I$ (since every $s \in I$ satisfies $s \leq k$), and the definition of $\alpha_I(k)$ yields $\alpha_I(k) = \left|\underbrace{\{s \in I \mid s \leq k\}}_{=I}\right| = |I|$. Similarly, $\alpha_J(k) = |J|$. Applying $\alpha_I(\ell) \geq \alpha_J(\ell)$ to $\ell = k$, we obtain $\alpha_I(k) \geq \alpha_J(k)$, so that $|I| = \alpha_I(k) \geq \alpha_J(k) = |J|$, and thus Property α is proven.

Now, let $r \in \{1, 2, \ldots, |J|\}$. The r-th smallest element of I and the r-th smallest element of J are then well-defined (because of $r \leq |J| \leq |I|$). Let ℓ be the r-th smallest element of J. Then, $\{s \in J \mid s \leq \ell\}$ is the set consisting of the r smallest elements of J, so that $|\{s \in J \mid s \leq \ell\}| = r$. Now, $\alpha_J(\ell) = |\{s \in J \mid s \leq \ell\}| = r$.

But $\alpha_I(\ell) = |\{s \in I \mid s \leq \ell\}|$, so that

$$|\{s \in I \mid s \leq \ell\}| = \alpha_I(\ell) \geq \alpha_J(\ell) = r.$$

In other words, there exist at least r elements of I which are $\leq \ell$. Hence, the r-th smallest element of I must be $\leq \ell$. Since ℓ is the r-th smallest element of J, this rewrites as follows: The r-th smallest element of I is $\leq$ to the r-th smallest element of J. Thus, Property β holds. Now we know that both Properties α and β hold. Hence, $I \leq_{\#} J$ holds (which, as we know, is equivalent to the conjunction of said properties). This proves the $\Longleftarrow$ direction of (13.91.19). Thus, (13.91.19) is proven. In other words, Proposition 13.91.2(b) is proven.

(a) For every $\ell \in [k]$ and $S \subset [k]$, let $\alpha_S(\ell)$ denote the number $|\{s \in S \mid s \leq \ell\}|$. Thus, every $\ell \in [k]$ satisfies

$$\begin{aligned}\alpha_I(\ell) + \alpha_{[k]\setminus I}(\ell) &= |\{s \in I \mid s \leq \ell\}| + |\{s \in [k] \setminus I \mid s \leq \ell\}| \\ &= \left|\left\{s \in \underbrace{I \cup ([k] \setminus I)}_{=[k]} \mid s \leq \ell\right\}\right| \qquad (\text{since } I \text{ and } [k] \setminus I \text{ are disjoint}) \\ &= |\{s \in [k] \mid s \leq \ell\}| = \ell,\end{aligned}$$

so that $\alpha_{[k]\setminus I}(\ell) = \ell - \alpha_I(\ell)$. Similarly, every $\ell \in [k]$ satisfies $\alpha_{[k]\setminus J}(\ell) = \ell - \alpha_J(\ell)$.

Applying (13.91.19) to $[k] \setminus J$ and $[k] \setminus I$ in lieu of I and J, we obtain that

$$[k] \setminus J \leq_{\#} [k] \setminus I \text{ holds if and only if every } \ell \in [k] \text{ satisfies } \alpha_{[k]\setminus J}(\ell) \geq \alpha_{[k]\setminus I}(\ell). \tag{13.91.20}$$

Now, we have the following equivalence of assertions:

$$\begin{aligned}
&\left([k] \setminus J \leq_{\#} [k] \setminus I\right) \\
\iff &\left(\text{every } \ell \in [k] \text{ satisfies } \underbrace{\alpha_{[k]\setminus J}(\ell)}_{=\ell - \alpha_J(\ell)} \geq \underbrace{\alpha_{[k]\setminus I}(\ell)}_{=\ell-\alpha_I(\ell)}\right) \qquad (\text{by (13.91.20)}) \\
\iff &\left(\text{every } \ell \in [k] \text{ satisfies } \ell - \alpha_J(\ell) \geq \ell - \alpha_I(\ell)\right) \\
\iff &\left(\text{every } \ell \in [k] \text{ satisfies } \alpha_I(\ell) \geq \alpha_J(\ell)\right) \\
\iff &\left(I \leq_{\#} J\right) \qquad (\text{by (13.91.19)}).
\end{aligned}$$

This proves Proposition 13.91.2(a).

Returning to the solution of Exercise 2.9.15(d), we now define some more notations.

If T is a column-strict tableau and i is an integer, then the *i-th set column* of T will mean the set of the entries in the i-th column of T. Notice that the cardinality of the i-th set column of T is the length of the i-th column of the shape of T (since every column of a column-strict tableau has all its entries distinct), and that the i-th column of T can be uniquely reconstructed from the i-th set column of T (because the order of the entries in a column can only be increasing).

For every subset S of $[k]$, we define $\mathbf{x}_S$ to be the monomial $\prod_{s\in S} x_s$ in $\mathbf{k}[x_1, x_2, \ldots, x_k]$. If $(S_1, S_2, \ldots, S_m)$ is an m-tuple of subsets of $[k]$, then we set $\mathbf{x}_{(S_1,S_2,\ldots,S_m)} = \prod_{i=1}^m \mathbf{x}_{S_i}$.

Let λ^t denote the conjugate of the partition λ. Then, $(\lambda^t)_i$ is the length of the i-th column of the Ferrers diagram of λ for every $i \in \{1, 2, \ldots, m\}$.

Let $A(\lambda)$ denote the set of all m-tuples $(I_1, I_2, \ldots, I_m)$ of subsets of $[k]$ satisfying $I_1 \leq_{\#} I_2 \leq_{\#} \cdots \leq_{\#} I_m$ and $\left(|I_i| = (\lambda^t)_i \text{ for every } i \in \{1, 2, \ldots, m\}\right)$. Note that we denote it by $A(\lambda)$ to stress its dependency on λ.

Let $(\lambda^\vee)^t$ denote the conjugate of the partition $\lambda^\vee$. It is easy to see that

$$\left((\lambda^\vee)^t\right)_i = k - \left(\lambda^t\right)_{m+1-i} \qquad \text{for every } i \in \{1, 2, \ldots, m\}. \tag{13.91.21}$$

720

[720] *Proof of (13.91.21):* Fix $i \in \{1, 2, \ldots, m\}$. We recall that $\lambda^\vee = (m - \lambda_k, m - \lambda_{k-1}, \ldots, m - \lambda_1)$. Hence,

$$\left(\lambda^\vee\right)_j = m - \lambda_{k+1-j} \qquad \text{for every } j \in \{1, 2, \ldots, k\}. \tag{13.91.22}$$

Also, $\ell(\lambda^\vee) \leq k$ (since $\lambda^\vee = (m - \lambda_k, m - \lambda_{k-1}, \ldots, m - \lambda_1)$), so that every positive integer $j > k$ satisfies $(\lambda^\vee)_j = 0$. Thus, every positive integer j satisfying $(\lambda^\vee)_j \geq i$ must belong to $\{1, 2, \ldots, k\}$ (since otherwise, this j would satisfy $j > k$, and thus $(\lambda^\vee)_j = 0$, which would contradict $(\lambda^\vee)_j \geq i > 0$). Hence,

$$\begin{aligned}
\left\{j \mid (\lambda^\vee)_j \geq i\right\} &= \left\{ j \in \{1, 2, \ldots, k\} \mid \underbrace{(\lambda^\vee)_j}_{\substack{=m-\lambda_{k+1-j} \\ (\text{by (13.91.22)})}} \geq i \right\} = \left\{ j \in \{1, 2, \ldots, k\} \mid \underbrace{m - \lambda_{k+1-j} \geq i}_{\substack{\text{this is equivalent to } \lambda_{k+1-j} \leq m-i, \text{ and thus} \\ \text{also equivalent to } \lambda_{k+1-j} < m-i+1 \\ (\text{since } \lambda_{k+1-j} \text{ and } m-i \text{ are integers})}} \right\} \\
&= \left\{ j \in \{1, 2, \ldots, k\} \mid \lambda_{k+1-j} < m - i + 1 \right\} \\
&= \{1, 2, \ldots, k\} \setminus \left\{ j \in \{1, 2, \ldots, k\} \mid \lambda_{k+1-j} \geq m - i + 1 \right\}.
\end{aligned}$$

But applying (2.2.7) to $\lambda^\vee$ instead of λ, we obtain

$$\begin{aligned}
\left((\lambda^\vee)^t\right)_i &= \left| \underbrace{\left\{ j \mid (\lambda^\vee)_j \geq i \right\}}_{=\{1,2,\ldots,k\} \setminus \left\{j \in \{1,2,\ldots,k\} \mid \lambda_{k+1-j} \geq m-i+1\right\}} \right| = \left| \{1, 2, \ldots, k\} \setminus \left\{ j \in \{1, 2, \ldots, k\} \mid \lambda_{k+1-j} \geq m - i + 1 \right\} \right| \\
&= \underbrace{\left|\{1, 2, \ldots, k\}\right|}_{=k} - \underbrace{\left| \left\{ j \in \{1, 2, \ldots, k\} \mid \lambda_{k+1-j} \geq m - i + 1 \right\} \right|}_{\substack{=\left|\left\{j \in \{1,2,\ldots,k\} \mid \lambda_j \geq m-i+1\right\}\right| \\ (\text{here, we have substituted } j \text{ for } k+1-j)}} \\
&= k - \left| \left\{ j \in \{1, 2, \ldots, k\} \mid \lambda_j \geq m - i + 1 \right\} \right|. \qquad (13.91.23)
\end{aligned}$$

But $\ell(\lambda) \leq k$, so that every positive integer $j > k$ satisfies $\lambda_j = 0$. Thus, every positive integer j satisfying $\lambda_j \geq m-i+1$ must belong to $\{1, 2, \ldots, k\}$ (since otherwise, this j would satisfy $j > k$, and thus $\lambda_j = 0$, which would contradict $\lambda_j \geq m-i+1 > 0$).

It is easy to see (from the definition of $\lambda^\vee$) that $\lambda^\vee$ is a partition satisfying $\ell(\lambda^\vee) \leq k$, and all parts of $\lambda^\vee$ are $\leq m$. Hence, we can define a set $A(\lambda^\vee)$ in the same way as we defined the set $A(\lambda)$ (but with every λ replaced by $\lambda^\vee$). Explicitly, $A(\lambda^\vee)$ is the set of all m-tuples $(I_1, I_2, \ldots, I_m)$ of subsets of $[k]$ satisfying $I_1 \leq_\# I_2 \leq_\# \cdots \leq_\# I_m$ and $\left(|I_i| = \left((\lambda^\vee)^t\right)_i \text{ for every } i \in \{1, 2, \ldots, m\}\right)$.

Define a map

$$\varphi(\lambda) : (\text{the set of all } (\lambda, k)\text{-CSTs}) \to A(\lambda)$$

by sending every (λ, k)-CST T to the m-tuple whose i-th entry is the i-th set column of T. This map is well-defined[721], injective[722] and surjective[723]. Hence, $\varphi(\lambda)$ is a bijection. This bijection $\varphi(\lambda)$ furthermore satisfies

$$\mathbf{x}_{(\varphi(\lambda))(T)} = \mathbf{x}^{\operatorname{cont}(T)} \qquad \text{for every } (\lambda, k)\text{-CST } T \tag{13.91.25}$$

[724]. Substituting x_1^{-1}, x_2^{-1}, $\ldots$, x_k^{-1} for x_1, x_2, $\ldots$, x_k on both sides of this equality, we obtain

$$\left(\mathbf{x}_{(\varphi(\lambda))(T)}\right)^{-1} = \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}(T)} \qquad \text{for every } (\lambda, k)\text{-CST } T \tag{13.91.26}$$

(in fact, $\mathbf{x}_{(\varphi(\lambda))(T)}$ is a monomial, so that substituting x_1^{-1}, x_2^{-1}, $\ldots$, x_k^{-1} for x_1, x_2, $\ldots$, x_k transforms it into its inverse $\left(\mathbf{x}_{(\varphi(\lambda))(T)}\right)^{-1}$).

Recall that $\lambda^\vee$ is a partition satisfying $\ell(\lambda^\vee) \leq k$, and all parts of $\lambda^\vee$ are $\leq m$. Hence, we can define a bijection

$$\varphi(\lambda^\vee) : (\text{the set of all } (\lambda^\vee, k)\text{-CSTs}) \to A(\lambda^\vee)$$

in the same way as we defined the bijection $\varphi(\lambda) : (\text{the set of all } (\lambda, k)\text{-CSTs}) \to A(\lambda)$ (but with $\lambda^\vee$ instead of λ). This bijection satisfies

$$\mathbf{x}_{(\varphi(\lambda^\vee))(T)} = \mathbf{x}^{\operatorname{cont}(T)} \qquad \text{for every } (\lambda^\vee, k)\text{-CST } T \tag{13.91.27}$$

Hence,

$$\{j \mid \lambda_j \geq m - i + 1\} = \{j \in \{1, 2, \ldots, k\} \mid \lambda_j \geq m - i + 1\}.$$

Now, (2.2.7) (applied to $m - i + 1$ instead of i) yields

$$\left(\lambda^t\right)_{m-i+1} = \left| \underbrace{\{j \mid \lambda_j \geq m - i + 1\}}_{= \{j \in \{1,2,\ldots,k\} \mid \lambda_j \geq m-i+1\}} \right| = \left|\{j \in \{1, 2, \ldots, k\} \mid \lambda_j \geq m - i + 1\}\right|. \tag{13.91.24}$$

Thus, (13.91.23) becomes

$$\left((\lambda^\vee)^t\right)_i = k - \underbrace{\left|\{j \in \{1, 2, \ldots, k\} \mid \lambda_j \geq m - i + 1\}\right|}_{\substack{= (\lambda^t)_{m-i+1} \\ \text{(by (13.91.24))}}} = k - \left(\lambda^t\right)_{m-i+1} = k - \left(\lambda^t\right)_{m+1-i}.$$

This proves (13.91.21).

[721] Indeed, if T is an (λ, k)-CST, then the m-tuple whose i-th entry is the i-th set column of T belongs to $A(\lambda)$ (because if we denote this m-tuple by $(I_1, I_2, \ldots, I_m)$, then

$$\begin{aligned} |I_i| &= |(\text{the } i\text{-th set column of } T)| = (\text{the length of the } i\text{-th column of } T) \\ &= (\text{the length of the } i\text{-th column of the Ferrers diagram of } \lambda) \\ &\qquad (\text{since } T \text{ is a } (\lambda, k)\text{-CST, thus a column-strict tableau of shape } \lambda) \\ &= \left(\lambda^t\right)_i, \end{aligned}$$

and the fact that the entries of T increase weakly along rows (because T is a column-strict tableau) translates precisely into the inequality chain $I_1 \leq_\# I_2 \leq_\# \cdots \leq_\# I_m$).

[722] This is because the i-th column of a (λ, k)-CST T can be uniquely reconstructed from the i-th set column of T (indeed, the entries of the i-th column of T must be strictly increasing down the column, and therefore the knowledge of the set of these entries is sufficient to recover the i-th column). Here, we are using the fact that T has at most m columns (since every part of λ is $\leq m$).

[723] Indeed, given any $(I_1, I_2, \ldots, I_m) \in A(\lambda)$. Then, $(I_1, I_2, \ldots, I_m)$ is an m-tuple of subsets of $[k]$ satisfying $I_1 \leq_\# I_2 \leq_\# \cdots \leq_\# I_m$ and $\left(|I_i| = \left(\lambda^t\right)_i \text{ for every } i \in \{1, 2, \ldots, m\}\right)$. Now, we can fill in each column of the Ferrers diagram of λ with the entries of the corresponding set I_i in increasing order, and then the resulting filling is a column-strict tableau (indeed, its entries increase weakly along its rows (due to $I_1 \leq_\# I_2 \leq_\# \cdots \leq_\# I_m$)), and more precisely a (λ, k)-CST. Our m-tuple $(I_1, I_2, \ldots, I_m)$ is the image of this (λ, k)-CST under $\varphi(\lambda)$; therefore, $(I_1, I_2, \ldots, I_m)$ lies in the image of $\varphi(\lambda)$. Hence, we have shown that every $(I_1, I_2, \ldots, I_m) \in A(\lambda)$ lies in the image of $\varphi(\lambda)$. The map $\varphi(\lambda)$ is thus surjective, qed.

[724] Indeed, it is easy to check that both $\mathbf{x}_{(\varphi(\lambda))(T)}$ and $\mathbf{x}^{\operatorname{cont}(T)}$ are equal to the product $\prod_{c \text{ is a cell of } T} x_{(\text{entry of } T \text{ in } c)}$.

(this can be shown in analogy to (13.91.25)).

Finally, we define a map $\psi(\lambda) : A(\lambda) \to A(\lambda^\vee)$ as follows: For every $(I_1, I_2, \ldots, I_m) \in A(\lambda)$, let

$$(\psi(\lambda))(I_1, I_2, \ldots, I_m) = ([k] \setminus I_m, [k] \setminus I_{m-1}, \ldots, [k] \setminus I_1).$$

This map $\psi(\lambda)$ is well-defined[725] and bijective[726]. This bijective map $\psi(\lambda)$ has the property that

$$\mathbf{x}_{(\psi(\lambda))(S)} = (x_1 x_2 \cdots x_k)^m \cdot (\mathbf{x}_S)^{-1} \qquad \text{for every } S \in A(\lambda) \tag{13.91.28}$$

[727].

Using the three bijective maps

$$\varphi(\lambda) : (\text{the set of all } (\lambda, k)\text{-CSTs}) \to A(\lambda),$$
$$\psi(\lambda) : A(\lambda) \to A(\lambda^\vee),$$
$$\varphi(\lambda^\vee) : (\text{the set of all } (\lambda^\vee, k)\text{-CSTs}) \to A(\lambda^\vee),$$

we can define a map

$$\Omega : (\text{the set of all } (\lambda, k)\text{-CSTs}) \to (\text{the set of all } (\lambda^\vee, k)\text{-CSTs})$$

by $\Omega = (\varphi(\lambda^\vee))^{-1} \circ (\psi(\lambda)) \circ (\varphi(\lambda))$. Clearly, this Ω is a bijection. If we can show that every (λ, k)-CST T satisfies (13.91.18), then (13.91.17) will be proven, and thus Exercise 2.9.15(d) will be solved again. Hence, all that remains to prove now is that every (λ, k)-CST T satisfies (13.91.18).

[725] *Proof.* Let $(I_1, I_2, \ldots, I_m) \in A(\lambda)$. Then, $(I_1, I_2, \ldots, I_m)$ is an m-tuple of subsets of $[k]$ satisfying $I_1 \leq_\# I_2 \leq_\# \cdots \leq_\# I_m$ and $\left(|I_i| = (\lambda^t)_i \text{ for every } i \in \{1, 2, \ldots, m\}\right)$.

In order to prove the well-definedness of $\psi(\lambda)$, we need to show that $([k] \setminus I_m, [k] \setminus I_{m-1}, \ldots, [k] \setminus I_1) \in A(\lambda^\vee)$. In other words, we need to prove that $([k] \setminus I_m, [k] \setminus I_{m-1}, \ldots, [k] \setminus I_1)$ is an m-tuple of subsets of $[k]$ satisfying $[k] \setminus I_m \leq_\# [k] \setminus I_{m-1} \leq_\# \cdots \leq_\# [k] \setminus I_1$ and $\left(|[k] \setminus I_{m+1-i}| = \left((\lambda^\vee)^t\right)_i \text{ for every } i \in \{1, 2, \ldots, m\}\right)$.

First of all, it is clear that $([k] \setminus I_m, [k] \setminus I_{m-1}, \ldots, [k] \setminus I_1)$ is an m-tuple of subsets of $[k]$. Furthermore, $[k] \setminus I_m \leq_\# [k] \setminus I_{m-1} \leq_\# \cdots \leq_\# [k] \setminus I_1$ follows from $I_1 \leq_\# I_2 \leq_\# \cdots \leq_\# I_m$ (according to Proposition 13.91.2(a)). Thus, it remains to prove that $|[k] \setminus I_{m+1-i}| = \left((\lambda^\vee)^t\right)_i$ for every $i \in \{1, 2, \ldots, m\}$.

So fix some $i \in \{1, 2, \ldots, m\}$. Then, $|I_{m+1-i}| = (\lambda^t)_{m+1-i}$ (this follows from the $|I_i| = (\lambda^t)_i$ formula, but applied to $m + 1 - i$ instead of i). Since $I_{m+1-i} \subset [k]$, we have

$$|[k] \setminus I_{m+1-i}| = \underbrace{|[k]|}_{=k} - \underbrace{|I_{m+1-i}|}_{=(\lambda^t)_{m+1-i}} = k - (\lambda^t)_{m+1-i} = \left((\lambda^\vee)^t\right)_i \qquad (\text{by } (13.91.21)),$$

qed.

[726] Indeed, we can define a map $\psi(\lambda^\vee)$ in the same way as we have defined $\psi(\lambda)$ (but with $\lambda^\vee$ instead of λ). It is then easy to see that the maps $\psi(\lambda)$ and $\psi(\lambda^\vee)$ are mutually inverse, so that $\psi(\lambda)$ is bijective, qed.

[727] *Proof of (13.91.28):* Let $S \in A(\lambda)$. Then, S is an m-tuple of subsets of $[k]$. Write S as $S = (I_1, I_2, \ldots, I_m)$. The definition of $\mathbf{x}_S$ then yields

$$\mathbf{x}_S = \prod_{i=1}^m \mathbf{x}_{I_i}.$$

Hence,

$$(x_1 x_2 \cdots x_k)^m \cdot (\mathbf{x}_S)^{-1} = (x_1 x_2 \cdots x_k)^m \cdot \left(\prod_{i=1}^m \mathbf{x}_{I_i}\right)^{-1} = \prod_{i=1}^m \frac{x_1 x_2 \cdots x_k}{\mathbf{x}_{I_i}}. \tag{13.91.29}$$

On the other hand, the definition of $\psi(\lambda)$ yields $(\psi(\lambda))(S) = ([k] \setminus I_m, [k] \setminus I_{m-1}, \ldots, [k] \setminus I_1)$, and thus (by the definition of $\mathbf{x}_{(\psi(\lambda))(S)}$) we have

$$\mathbf{x}_{(\psi(\lambda))(S)} = \prod_{i=1}^m \mathbf{x}_{[k] \setminus I_{m+1-i}} = \prod_{i=1}^m \mathbf{x}_{[k] \setminus I_i} \qquad (\text{here, we substituted } m + 1 - i \text{ for } i \text{ in the product}). \tag{13.91.30}$$

But we need to prove (13.91.28). In view of (13.91.29) and (13.91.30), this boils down to proving that $\prod_{i=1}^m \mathbf{x}_{[k] \setminus I_i} = \prod_{i=1}^m \frac{x_1 x_2 \cdots x_k}{\mathbf{x}_{I_i}}$. But this will immediately follow if we can prove the identity $\mathbf{x}_{[k] \setminus I_i} = \frac{x_1 x_2 \cdots x_k}{\mathbf{x}_{I_i}}$ for every $i \in \{1, 2, \ldots, m\}$. But the latter identity follows from the (obvious) fact that $\mathbf{x}_{[k] \setminus S} = \frac{x_1 x_2 \cdots x_k}{\mathbf{x}_S}$ for every $S \subset [k]$. Thus, (13.91.28) is proven.

Let T be a (λ, k)-CST. We have $\Omega = \left(\varphi\left(\lambda^\vee\right)\right)^{-1} \circ \left(\psi\left(\lambda\right)\right) \circ \left(\varphi\left(\lambda\right)\right)$, thus $\left(\varphi\left(\lambda^\vee\right)\right) \circ \Omega = \left(\psi\left(\lambda\right)\right) \circ \left(\varphi\left(\lambda\right)\right)$. Applying (13.91.27) to $\Omega\left(T\right)$ instead of T, we obtain $\mathbf{x}_{\left(\varphi\left(\lambda^\vee\right)\right)\left(\Omega\left(T\right)\right)} = \mathbf{x}^{\operatorname{cont}\left(\Omega\left(T\right)\right)}$, whence

$$\begin{aligned}
\mathbf{x}^{\operatorname{cont}\left(\Omega\left(T\right)\right)} &= \mathbf{x}_{\left(\varphi\left(\lambda^\vee\right)\right)\left(\Omega\left(T\right)\right)} = \mathbf{x}_{\left(\psi\left(\lambda\right)\right)\left(\left(\varphi\left(\lambda\right)\right)\left(T\right)\right)} \\
&\qquad \left(\text{since } \left(\varphi\left(\lambda^\vee\right)\right)\left(\Omega\left(T\right)\right) = \underbrace{\left(\left(\varphi\left(\lambda^\vee\right)\right) \circ \Omega\right)}_{=\left(\psi\left(\lambda\right)\right)\circ\left(\varphi\left(\lambda\right)\right)}\left(T\right) = \left(\left(\psi\left(\lambda\right)\right) \circ \left(\varphi\left(\lambda\right)\right)\right)\left(T\right) = \left(\psi\left(\lambda\right)\right)\left(\left(\varphi\left(\lambda\right)\right)\left(T\right)\right)\right) \\
&= \left(x_1 x_2 \cdots x_k\right)^m \cdot \underbrace{\left(\mathbf{x}_{\left(\varphi\left(\lambda\right)\right)\left(T\right)}\right)^{-1}}_{\substack{=\left(\mathbf{x}^{-1}\right)^{\operatorname{cont}\left(T\right)} \\ \text{(by (13.91.26))}}} \qquad \left(\text{by (13.91.28), applied to } S = \left(\varphi\left(\lambda\right)\right)\left(T\right)\right) \\
&= \left(x_1 x_2 \cdots x_k\right)^m \cdot \left(\mathbf{x}^{-1}\right)^{\operatorname{cont}\left(T\right)}.
\end{aligned}$$

Thus, (13.91.18) holds. We thus have proven that every (λ, k)-CST T satisfies (13.91.18). Exercise 2.9.15(d) is thus solved.

(e) *First solution to Exercise 2.9.15(e):* Obviously, the k-tuple $\left(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k\right)$ is a partition. Let us denote this partition by $\lambda^{[r]}$. Then, $\lambda^{[r]} = \left(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k\right)$ and $\ell\left(\lambda^{[r]}\right) \leq k$.

Let $n = k$. We shall use the notations of Section 2.6; in particular, we set $\mathbf{x} = \left(x_1, x_2, \ldots, x_n\right)$ and $\rho = \left(n-1, n-2, \ldots, 2, 1, 0\right)$. Clearly, $\mathbf{x} = \left(x_1, x_2, \ldots, x_n\right) = \left(x_1, x_2, \ldots, x_k\right)$ (since $n = k$). Notice that $\ell\left(\lambda\right) \leq k = n$. Hence, we can regard λ as an element of $\mathbb{N}^n$; therefore, $\lambda + \rho$ is a well-defined element of $\mathbb{N}^n$, and the alternant $a_{\lambda+\rho}$ is well-defined. Corollary 2.6.7 yields that $s_\lambda\left(\mathbf{x}\right) = \dfrac{a_{\lambda+\rho}}{a_\rho}$, so that

$$a_\rho \cdot s_\lambda\left(\mathbf{x}\right) = a_{\lambda+\rho}. \tag{13.91.31}$$

Applying this equality to $\lambda^{[r]}$ instead of λ, we obtain

$$a_\rho \cdot s_{\lambda^{[r]}}\left(\mathbf{x}\right) = a_{\lambda^{[r]}+\rho} \tag{13.91.32}$$

(since $\lambda^{[r]}$ is also a partition satisfying $\ell\left(\lambda^{[r]}\right) \leq k = n$).

We have (13.91.7), and every $\alpha = \left(\alpha_1, \alpha_2, \ldots, \alpha_n\right) \in \mathbb{N}^n$ satisfies (13.91.6). (This can be proven just as in the First solution to Exercise 2.9.15(d).)

We have $\lambda^{[r]} = \left(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k\right) = \left(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_n\right)$ (since $k = n$), so that

$$\begin{aligned}
\underbrace{\lambda^{[r]}}_{=\left(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_n\right)} + \underbrace{\rho}_{\substack{=\left(n-1, n-2, \ldots, 2, 1, 0\right) \\ =\left(n-1, n-2, \ldots, n-n\right)}} &= \left(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_n\right) + \left(n-1, n-2, \ldots, n-n\right) \\
&= \left(\left(r+\lambda_1\right) + \left(n-1\right), \left(r+\lambda_2\right) + \left(n-2\right), \ldots, \left(r+\lambda_n\right) + \left(n-n\right)\right).
\end{aligned}$$

Hence, (13.91.6) (applied to $\lambda^{[r]} + \rho$ and $((r+\lambda_1)+(n-1), (r+\lambda_2)+(n-2), \ldots, (r+\lambda_n)+(n-n))$ instead of α and $(\alpha_1, \alpha_2, \ldots, \alpha_n)$) yields

$$\begin{aligned}
& a_{\lambda^{[r]}+\rho} \\
&= \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} \underbrace{x_{w(i)}^{(r+\lambda_i)+(n-i)}}_{=x_{w(i)}^{r+(\lambda_i+n-i)}=x_{w(i)}^{r}x_{w(i)}^{\lambda_i+n-i}} \\
&= \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \underbrace{\prod_{i=1}^{n}\left(x_{w(i)}^{r}x_{w(i)}^{\lambda_i+n-i}\right)}_{=\left(\prod_{i=1}^{n} x_{w(i)}^{r}\right)\left(\prod_{i=1}^{n} x_{w(i)}^{\lambda_i+n-i}\right)} = \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \underbrace{\left(\prod_{i=1}^{n} x_{w(i)}^{r}\right)}_{\substack{=\prod_{i=1}^{n} x_i^r \\ \text{(here, we have substituted } i \text{ for} \\ w(i) \text{ in the product (since } w \text{ is} \\ \text{a permutation of } \{1,2,\ldots,n\}))}} \left(\prod_{i=1}^{n} x_{w(i)}^{\lambda_i+n-i}\right) \\
&= \sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \left(\prod_{i=1}^{n} x_i^r\right)\left(\prod_{i=1}^{n} x_{w(i)}^{\lambda_i+n-i}\right) = \underbrace{\left(\prod_{i=1}^{n} x_i^r\right)}_{=x_1^r x_2^r \cdots x_n^r=(x_1x_2\cdots x_n)^r} \cdot \underbrace{\sum_{w\in\mathfrak{S}_n} \operatorname{sgn}(w) \prod_{i=1}^{n} x_{w(i)}^{\lambda_i+n-i}}_{\substack{=a_{\lambda+\rho} \\ \text{(by (13.91.7))}}} \\
&= (x_1x_2\cdots x_n)^r \cdot \underbrace{a_{\lambda+\rho}}_{\substack{=a_\rho \cdot s_\lambda(\mathbf{x}) \\ \text{(by (13.91.31))}}} = (x_1x_2\cdots x_n)^r \cdot a_\rho \cdot s_\lambda(\mathbf{x}) = a_\rho \cdot (x_1x_2\cdots x_n)^r \cdot s_\lambda(\mathbf{x}).
\end{aligned}$$

Hence, $a_\rho \cdot (x_1x_2\cdots x_n)^r \cdot s_\lambda(\mathbf{x}) = a_{\lambda^{[r]}+\rho} = a_\rho \cdot s_{\lambda^{[r]}}(\mathbf{x})$ (by (13.91.31)).

But we know (from a footnote in Corollary 2.6.7) that a_ρ is not a zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$. In other words, a_ρ is a non-zero-divisor in the ring $\mathbf{k}[x_1, x_2, \ldots, x_n]$. Hence, we can cancel the factor a_ρ from the equality $a_\rho \cdot (x_1x_2\cdots x_n)^r \cdot s_\lambda(\mathbf{x}) = a_\rho \cdot s_{\lambda^{[r]}}(\mathbf{x})$. As a result, we obtain $(x_1x_2\cdots x_n)^r \cdot s_\lambda(\mathbf{x}) = s_{\lambda^{[r]}}(\mathbf{x}) = s_{\lambda^{[r]}}(x_1, x_2, \ldots, x_k)$ (since $\mathbf{x} = (x_1, x_2, \ldots, x_k)$), so that

$$s_{\lambda^{[r]}}(x_1, x_2, \ldots, x_k) = \Bigg(\underbrace{x_1x_2\cdots x_n}_{\substack{=x_1x_2\cdots x_k \\ \text{(since } n=k)}}\Bigg)^r \cdot \underbrace{s_\lambda(\mathbf{x})}_{\substack{=s_\lambda(x_1,x_2,\ldots,x_k) \\ \text{(since } \mathbf{x}=(x_1,x_2,\ldots,x_k))}} = (x_1x_2\cdots x_k)^r \cdot s_\lambda(x_1, x_2, \ldots, x_k).$$

Since $\lambda^{[r]} = s_{(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k)}$, this rewrites as

$$s_{(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k)}(x_1, x_2, \ldots, x_k) = (x_1x_2\cdots x_k)^r \cdot s_\lambda(x_1, x_2, \ldots, x_k).$$

This solves Exercise 2.9.15(e).

Second solution to Exercise 2.9.15(e) (sketched): Obviously, the k-tuple $(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k)$ is a partition. Let us denote this partition by $\lambda^{[r]}$. Then, $\lambda^{[r]} = (r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k)$ and $\ell\left(\lambda^{[r]}\right) \leq k$.

We have $(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k) = \lambda^{[r]}$, thus $s_{(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k)} = s_{\lambda^{[r]}} = s_{\lambda^{[r]}/\varnothing}$, hence

$$\begin{aligned}
& \underbrace{s_{(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k)}}_{=s_{\lambda^{[r]}/\varnothing}}(x_1, x_2, \ldots, x_k) \\
&= s_{\lambda^{[r]}/\varnothing}(x_1, x_2, \ldots, x_k) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda^{[r]}/\varnothing; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \mathbf{x}^{\operatorname{cont}(T)} \\
& \qquad \left(\text{by Exercise 2.3.8(a), applied to } k,\ \lambda^{[r]} \text{ and } \varnothing \text{ instead of } n,\ \lambda \text{ and } \mu\right) \\
&= \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda^{[r]}; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \mathbf{x}^{\operatorname{cont}(T)} \qquad (13.91.33)
\end{aligned}$$

(since column-strict tableaux of shape $\lambda^{[r]}/\varnothing$ are the same as column-strict tableaux of shape $\lambda^{[r]}$).

But an argument analogous to the one we just used to prove (13.91.33) (but with λ in place of $\lambda^{[r]}$) shows that

$$s_\lambda\left(x_1, x_2, \ldots, x_k\right) = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \mathbf{x}^{\operatorname{cont}(T)}.$$

Multiplied by $\left(x_1 x_2 \cdots x_k\right)^r$, this equality becomes

$$\begin{aligned} \left(x_1 x_2 \cdots x_k\right)^r \cdot s_\lambda\left(x_1, x_2, \ldots, x_k\right) &= \left(x_1 x_2 \cdots x_k\right)^r \cdot \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \mathbf{x}^{\operatorname{cont}(T)} \\ &= \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \left(x_1 x_2 \cdots x_k\right)^r \cdot \mathbf{x}^{\operatorname{cont}(T)}. \qquad (13.91.34) \end{aligned}$$

We need to prove that

$$s_{(r+\lambda_1, r+\lambda_2, \ldots, r+\lambda_k)}\left(x_1, x_2, \ldots, x_k\right) = \left(x_1 x_2 \cdots x_k\right)^r \cdot s_\lambda\left(x_1, x_2, \ldots, x_k\right).$$

Due to (13.91.33) and (13.91.34), this rewrites as

$$\sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda^{[r]}; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \mathbf{x}^{\operatorname{cont}(T)} = \sum_{\substack{T \text{ is a column-strict} \\ \text{tableau of shape } \lambda; \\ \text{all entries of } T \text{ belong} \\ \text{to } \{1,2,\ldots,k\}}} \left(x_1 x_2 \cdots x_k\right)^r \cdot \mathbf{x}^{\operatorname{cont}(T)}. \qquad (13.91.35)$$

So it remains to prove (13.91.35).

In order to prove (13.91.35), it is clearly sufficient to construct a bijection

$$\begin{aligned} \Omega : &\left(\text{the set of all column-strict tableaux } T \text{ of shape } \lambda^{[r]} \text{ such that all entries of } T \text{ belong to } \{1, 2, \ldots, k\}\right) \\ &\to \left(\text{the set of all column-strict tableaux } T \text{ of shape } \lambda \text{ such that all entries of } T \text{ belong to } \{1, 2, \ldots, k\}\right) \end{aligned}$$

with the property that every column-strict tableau T of shape $\lambda^{[r]}$ such that all entries of T belong to $\{1, 2, \ldots, k\}$ satisfies

$$\left(x_1 x_2 \cdots x_k\right)^r \cdot \mathbf{x}^{\operatorname{cont}(\Omega(T))} = \mathbf{x}^{\operatorname{cont}(T)}. \qquad (13.91.36)$$

Constructing such an Ω is easy: The map Ω just maps every column-strict tableau T of shape $\lambda^{[r]}$ to the tableau of shape λ obtained by removing the first r entries of each row of T, and moving all other entries to the left by r cells. To prove that Ω is bijective, we need to construct a map inverse to Ω; this latter map sends every column-strict tableau T of shape λ to the tableau of shape $\lambda^{[r]}$ obtained by moving all entries of T to the right by r cells, and filling the now-vacant first r columns as follows:

$$\begin{array}{cccc} 1 & 1 & \cdots & 1 \\ 2 & 2 & \cdots & 2 \\ \vdots & \vdots & \ddots & \vdots \\ k & k & \cdots & k \end{array}.$$

Proving that this map is well-defined and really inverse to Ω is left to the reader[728]. Anyway, we now know that Ω is bijective, and it is easy to check that (13.91.36) holds. This completes the second solution of Exercise 2.9.15(e).

[728] The main ingredient of this proof is the observation that if T is a column-strict tableau of shape $\lambda^{[r]}$ such that all entries of T belong to $\{1, 2, \ldots, k\}$, then the first r columns of T must look like this:

$$\begin{array}{cccc} 1 & 1 & \cdots & 1 \\ 2 & 2 & \cdots & 2 \\ \vdots & \vdots & \ddots & \vdots \\ k & k & \cdots & k \end{array}.$$

13.92. **Solution to Exercise 2.9.16.** *Solution to Exercise 2.9.16.* (a) We can apply Exercise 2.9.15(a) to μ, μ, $\mu^{\vee\{m\}}$ and $\mu^{\vee\{m\}}$ instead of λ, μ, $\lambda^{\vee}$ and $\mu^{\vee}$. As a consequence, we conclude that $\mu^{\vee\{m\}}$ and $\mu^{\vee\{m\}}$ are partitions, and that $s_{\mu/\mu} = s_{\mu^{\vee\{m\}}/\mu^{\vee\{m\}}}$. Thus, $\mu^{\vee\{m\}}$ is a partition. The same argument (but with m, μ and $\mu^{\vee\{m\}}$ replaced by n, ν and $\nu^{\vee\{n\}}$) yields that $\nu^{\vee\{n\}}$ is a partition. This solves Exercise 2.9.16(a).

(b) Assume that not all parts of λ are $\leq m+n$. Then, some part of λ is $> m+n$; hence, the greatest part of λ is $> m+n$. Thus, $\lambda_1 > m+n$ (since λ_1 is the greatest part of λ). As a consequence, $\lambda_1 - \mu_1 > \nu_1$ [729].

Now, we shall show that

$$\left(\begin{array}{c} \text{there exists no column-strict tableau } T \text{ of shape } \lambda/\mu \text{ with } \operatorname{cont}(T) = \nu \\ \text{having the property that each } \operatorname{cont}(T\mid_{\text{cols}\geq j}) \text{ is a partition} \end{array} \right). \tag{13.92.1}$$

Proof of (13.92.1): Assume the contrary. Thus, there exists a column-strict tableau T of shape λ/μ with $\operatorname{cont}(T) = \nu$ having the property that each $\operatorname{cont}(T\mid_{\text{cols}\geq j})$ is a partition. Consider this T.

The column-strict tableau T has shape λ/μ, and thus its 1-st row has $\lambda_1 - \mu_1$ entries. In other words,

$$\begin{aligned} &(\text{the number of entries in the 1-st row of } T) \\ &= \lambda_1 - \mu_1 > \nu_1 = (\operatorname{cont}(T))_1 \qquad (\text{since } \nu = \operatorname{cont}(T)) \\ &= \left|T^{-1}(1)\right| \qquad (\text{by the definition of } \operatorname{cont}(T)) \\ &= (\text{the number of entries of } T \text{ equal to } 1). \end{aligned}$$

Hence, the tableau T has more entries in its 1-st row than it has entries equal to 1. Consequently, not every entry in the 1-st row is equal to 1. Thus, there exists an entry in the 1-st row of T which is > 1. Let k be this entry, and let $\mathbf{c}$ be the cell it occupies. Then, $\mathbf{c}$ is a cell in the 1-st row of T, and thus can be written in the form $(1, j)$ for some positive integer j. Consider this j. The cell $\mathbf{c}$ lies in column j, and thus is a cell of the skew tableau $T\mid_{\text{cols}\geq j}$; its entry is $(T\mid_{\text{cols}\geq j})(\mathbf{c}) = T(\mathbf{c}) = k$ (since we know that k is the entry of T occupying cell $\mathbf{c}$). Hence, $\mathbf{c} \in (T\mid_{\text{cols}\geq j})^{-1}(k)$, so that the set $(T\mid_{\text{cols}\geq j})^{-1}(k)$ is nonempty. Thus, $\left|(T\mid_{\text{cols}\geq j})^{-1}(k)\right| > 0$.

Recalling the definition of $\operatorname{cont}(T\mid_{\text{cols}\geq j})$, we see that $(\operatorname{cont}(T\mid_{\text{cols}\geq j}))_k = \left|(T\mid_{\text{cols}\geq j})^{-1}(k)\right| > 0$.

But we know that $\operatorname{cont}(T\mid_{\text{cols}\geq j})$ is a partition. Thus,

$$(\operatorname{cont}(T\mid_{\text{cols}\geq j}))_1 \geq (\operatorname{cont}(T\mid_{\text{cols}\geq j}))_2 \geq (\operatorname{cont}(T\mid_{\text{cols}\geq j}))_3 \geq \cdots,$$

so that $(\operatorname{cont}(T\mid_{\text{cols}\geq j}))_1 \geq (\operatorname{cont}(T\mid_{\text{cols}\geq j}))_k > 0$. But the definition of $\operatorname{cont}(T\mid_{\text{cols}\geq j})$ yields

$$(\operatorname{cont}(T\mid_{\text{cols}\geq j}))_1 = \left|(T\mid_{\text{cols}\geq j})^{-1}(1)\right| = (\text{the number of entries of } T\mid_{\text{cols}\geq j} \text{ equal to } 1).$$

Hence, $(\text{the number of entries of } T\mid_{\text{cols}\geq j} \text{ equal to } 1) = (\operatorname{cont}(T\mid_{\text{cols}\geq j}))_1 > 0$. Hence, the skew tableau $T\mid_{\text{cols}\geq j}$ must have at least one entry equal to 1.

But each cell of the skew tableau $T\mid_{\text{cols}\geq j}$ lies in one of the columns $j, j+1, j+2, \ldots$ (by the definition of $T\mid_{\text{cols}\geq j}$) and in one of the rows $1, 2, 3, \ldots$ (obviously). Hence, each cell of the skew tableau $T\mid_{\text{cols}\geq j}$ lies (weakly) southeast of the cell $(1, j) = \mathbf{c}$. As a consequence, each entry of the skew tableau $T\mid_{\text{cols}\geq j}$

(This is because each of the first r columns of T has length k, but the entries in this column must be strictly increasing from top to bottom, and knowing that these entries belong to $\{1, 2, \ldots, k\}$, we see that this is only possible if the column has the form $\begin{array}{c} 1 \\ 2 \\ \vdots \\ k \end{array}$.)

[729] *Proof.* All parts of μ are $\leq m$. Thus, $\mu_1 \leq m$ (since μ_1 is either a part of μ and therefore $\leq m$, or is zero and therefore $\leq m$ as well). Hence, $m \geq \mu_1$. Similarly, $n \geq \nu_1$. Now, $\lambda_1 > \underbrace{m}_{\geq \mu_1} + \underbrace{n}_{\geq \nu_1} \geq \mu_1 + \nu_1$, so that $\lambda_1 - \mu_1 > \nu_1$, qed.

is greater or equal to the entry of $T\mid_{\text{cols}\geq j}$ in the cell $\mathbf{c}$ [730]. Since the entry of $T\mid_{\text{cols}\geq j}$ in the cell $\mathbf{c}$ is $\left(T\mid_{\text{cols}\geq j}\right)(\mathbf{c})=k$, this yields that each entry of the skew tableau $T\mid_{\text{cols}\geq j}$ is greater or equal to k, and thus greater than 1 (since $k>1$). As a consequence, no entry of the skew tableau $T\mid_{\text{cols}\geq j}$ can be equal to 1. This contradicts the fact that the skew tableau $T\mid_{\text{cols}\geq j}$ must have at least one entry equal to 1. This contradiction proves that our assumption was wrong. Hence, (13.92.1) is proven.

Now, Corollary 2.6.12 yields that $c^{\lambda}_{\mu,\nu}$ counts column-strict tableaux T of shape λ/μ with $\operatorname{cont}(T)=\nu$ having the property that each $\operatorname{cont}\left(T\mid_{\text{cols}\geq j}\right)$ is a partition. Since there exists no such T (according to (13.92.1)), this yields that $c^{\lambda}_{\mu,\nu}=0$. This solves Exercise 2.9.16(b).

Remark: An alternative solution of Exercise 2.9.16(b) can be obtained easily from Exercise 2.9.17(c).

(c) Let us forget that λ is fixed.

If $\lambda\in\operatorname{Par}$ is such that $\ell(\lambda)>k$, then

$$s_{\lambda}(x_1,x_2,\ldots,x_k)=0. \tag{13.92.2}$$

[731]

We first notice that

$$s_{\mu}(x_1,x_2,\ldots,x_k)\cdot s_{\nu}(x_1,x_2,\ldots,x_k)=\sum_{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k}c^{\lambda}_{\mu,\nu}s_{\lambda}(x_1,x_2,\ldots,x_k). \tag{13.92.3}$$

[732] Hence,

$$s_{\mu}(x_1,x_2,\ldots,x_k)\cdot s_{\nu}(x_1,x_2,\ldots,x_k)=\sum_{\substack{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k;\\ \text{all parts of }\lambda\text{ are }\leq m+n}}c^{\lambda}_{\mu,\nu}s_{\lambda}(x_1,x_2,\ldots,x_k). \tag{13.92.4}$$

[730] Indeed, T is a column-strict tableau, and thus the entries of T increase weakly left-to-right along rows, and increase strictly top-to-bottom in columns. Consequently, the entries of T increase weakly as one moves to the southeast. The same holds for the entries of $T\mid_{\text{cols}\geq j}$ (since $T\mid_{\text{cols}\geq j}$ is a restriction of T), and thus each entry of $T\mid_{\text{cols}\geq j}$ is greater or equal to the entry of $T\mid_{\text{cols}\geq j}$ in the cell $\mathbf{c}$ (because each cell of $T\mid_{\text{cols}\geq j}$ lies (weakly) southeast of the cell $\mathbf{c}$). Qed.

[731] *Proof of (13.92.2):* Let $\lambda\in\operatorname{Par}$ be such that $\ell(\lambda)>k$. Then, the number of parts of λ is $\ell(\lambda)>k$. Hence, Exercise 2.3.8(b) (applied to k instead of n) yields $s_{\lambda}(x_1,x_2,\ldots,x_k)=0$, qed.

[732] *Proof of (13.92.3):* We have $s_\mu s_\nu=\sum_\lambda c^{\lambda}_{\mu,\nu}s_\lambda$, where the sum ranges over all partitions λ (according to the definition of the coefficients $c^{\lambda}_{\mu,\nu}$). In other words, $s_\mu s_\nu=\sum_{\lambda\in\operatorname{Par}}c^{\lambda}_{\mu,\nu}s_\lambda$. Evaluating both sides of this equality at $(x_1,x_2,\ldots,x_k)$, we obtain

$$\begin{aligned}
&s_{\mu}(x_1,x_2,\ldots,x_k)\cdot s_{\nu}(x_1,x_2,\ldots,x_k)\\
&=\sum_{\lambda\in\operatorname{Par}}c^{\lambda}_{\mu,\nu}s_{\lambda}(x_1,x_2,\ldots,x_k)\\
&=\sum_{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k}c^{\lambda}_{\mu,\nu}s_{\lambda}(x_1,x_2,\ldots,x_k)+\sum_{\lambda\in\operatorname{Par};\ \ell(\lambda)>k}c^{\lambda}_{\mu,\nu}\underbrace{s_{\lambda}(x_1,x_2,\ldots,x_k)}_{\substack{=0\\ \text{(by (13.92.2))}}}\\
&=\sum_{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k}c^{\lambda}_{\mu,\nu}s_{\lambda}(x_1,x_2,\ldots,x_k)+\underbrace{\sum_{\lambda\in\operatorname{Par};\ \ell(\lambda)>k}c^{\lambda}_{\mu,\nu}0}_{=0}\\
&=\sum_{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k}c^{\lambda}_{\mu,\nu}s_{\lambda}(x_1,x_2,\ldots,x_k),
\end{aligned}$$

qed.

[733]

Define a set $\mathfrak{A}$ by

$$\mathfrak{A} = \{\alpha \in \operatorname{Par} \ \mid \ \ell(\alpha) \leq k; \text{ all parts of } \alpha \text{ are } \leq m+n\}. \tag{13.92.5}$$

For every partition λ, let $\lambda^{\vee\{m+n\}}$ denote the k-tuple $(m+n-\lambda_k, m+n-\lambda_{k-1}, \ldots, m+n-\lambda_1)$. It is straightforward to see that for every $\lambda \in \mathfrak{A}$, we have

$$\lambda^{\vee\{m+n\}} \in \mathfrak{A}. \tag{13.92.6}$$

Thus, the map

$$\mathfrak{A} \to \mathfrak{A}, \qquad \lambda \mapsto \lambda^{\vee\{m+n\}}$$

is well-defined. It is easy to see that this map is an involution (i.e., every $\lambda \in \mathfrak{A}$ satisfies $\left(\lambda^{\vee\{m+n\}}\right)^{\vee\{m+n\}} = \lambda$), thus a bijection.

Now, the summation sign "$\sum\limits_{\substack{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k;\\ \text{all parts of } \lambda \text{ are } \leq m+n}}$" in (13.92.4) rewrites as "$\sum_{\lambda\in\mathfrak{A}}$" (because of how we defined $\mathfrak{A}$). Hence, (13.92.4) rewrites as

$$s_\mu(x_1, x_2, \ldots, x_k) \cdot s_\nu(x_1, x_2, \ldots, x_k) = \sum_{\lambda\in\mathfrak{A}} c^\lambda_{\mu,\nu} s_\lambda(x_1, x_2, \ldots, x_k). \tag{13.92.7}$$

Hence, in the Laurent polynomial ring $\mathbf{k}\left[x_1, x_2, \ldots, x_k, x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right]$, we have

$$s_\mu\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \cdot s_\nu\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) = \sum_{\lambda\in\mathfrak{A}} c^\lambda_{\mu,\nu} s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right). \tag{13.92.8}$$

[734]

Now, it is straightforward to see that $\mu^{\vee\{m\}}$ and $\nu^{\vee\{n\}}$ are partitions satisfying $\ell\left(\mu^{\vee\{m\}}\right) \leq k$ and $\ell\left(\nu^{\vee\{n\}}\right) \leq k$; also, all parts of the partition $\mu^{\vee\{m\}}$ are $\leq m$, and all parts of the partition $\nu^{\vee\{n\}}$ are $\leq n$. Moreover,

$$\mu = \left(m - \left(\mu^{\vee\{m\}}\right)_k, m - \left(\mu^{\vee\{m\}}\right)_{k-1}, \ldots, m - \left(\mu^{\vee\{m\}}\right)_1\right) \tag{13.92.9}$$

and

$$\nu = \left(n - \left(\nu^{\vee\{n\}}\right)_k, n - \left(\nu^{\vee\{n\}}\right)_{k-1}, \ldots, n - \left(\nu^{\vee\{n\}}\right)_1\right) \tag{13.92.10}$$

[733] *Proof of (13.92.4):* From (13.92.3), we obtain

$$\begin{aligned}
& s_\mu(x_1, x_2, \ldots, x_k) \cdot s_\nu(x_1, x_2, \ldots, x_k) \\
&= \sum_{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k} c^\lambda_{\mu,\nu} s_\lambda(x_1, x_2, \ldots, x_k) \\
&= \sum_{\substack{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k;\\ \text{all parts of } \lambda \text{ are } \leq m+n}} c^\lambda_{\mu,\nu} s_\lambda(x_1, x_2, \ldots, x_k) + \sum_{\substack{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k;\\ \text{not all parts of } \lambda \text{ are } \leq m+n}} \underbrace{c^\lambda_{\mu,\nu}}_{\substack{=0\\ \text{(by Exercise 2.9.16(b))}}} s_\lambda(x_1, x_2, \ldots, x_k) \\
&= \sum_{\substack{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k;\\ \text{all parts of } \lambda \text{ are } \leq m+n}} c^\lambda_{\mu,\nu} s_\lambda(x_1, x_2, \ldots, x_k) + \underbrace{\sum_{\substack{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k;\\ \text{not all parts of } \lambda \text{ are } \leq m+n}} 0 s_\lambda(x_1, x_2, \ldots, x_k)}_{=0} \\
&= \sum_{\substack{\lambda\in\operatorname{Par};\ \ell(\lambda)\leq k;\\ \text{all parts of } \lambda \text{ are } \leq m+n}} c^\lambda_{\mu,\nu} s_\lambda(x_1, x_2, \ldots, x_k).
\end{aligned}$$

This proves (13.92.4).

[734] This follows by substituting the variables $x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}$ for $x_1, x_2, \ldots, x_k$ in the equality (13.92.7).

(this is still easy to verify). These observations lead us to the conclusion that we can apply (13.92.8) to $\mu^{\vee\{m\}}$, μ, $\nu^{\vee\{n\}}$ and ν instead of μ, $\mu^{\vee\{m\}}$, ν and $\nu^{\vee\{n\}}$. As a result, we obtain

$$\begin{aligned} s_{\mu^{\vee\{m\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \cdot s_{\nu^{\vee\{n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) &= \sum_{\lambda \in \mathfrak{A}} c^{\lambda}_{\mu^{\vee\{m\}}, \nu^{\vee\{n\}}} s_\lambda\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \\ &= \sum_{\lambda \in \mathfrak{A}} c^{\lambda^{\vee\{m+n\}}}_{\mu^{\vee\{m\}}, \nu^{\vee\{n\}}} s_{\lambda^{\vee\{m+n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \qquad (13.92.11) \end{aligned}$$

(here, we have substituted $\lambda^{\vee\{m+n\}}$ for the summation index λ (since the map $\mathfrak{A} \to \mathfrak{A}$, $\lambda \mapsto \lambda^{\vee\{m+n\}}$ is a bijection)).

Now, we can apply Exercise 2.9.15(d) to $\mu^{\vee\{m\}}$, $\mu^{\vee\{m\}}$, μ and μ instead of λ, μ, $\lambda^\vee$ and $\mu^\vee$ (because of (13.92.9)). As a result, we obtain

$$s_\mu\left(x_1, x_2, \ldots, x_k\right) = \left(x_1 x_2 \cdots x_k\right)^m \cdot s_{\mu^{\vee\{m\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right). \qquad (13.92.12)$$

Also, we can apply Exercise 2.9.15(d) to n, $\nu^{\vee\{n\}}$, $\nu^{\vee\{n\}}$, ν and ν instead of m, λ, μ, $\lambda^\vee$ and $\mu^\vee$ (because of (13.92.10)). As a result, we obtain

$$s_\nu\left(x_1, x_2, \ldots, x_k\right) = \left(x_1 x_2 \cdots x_k\right)^n \cdot s_{\nu^{\vee\{n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right). \qquad (13.92.13)$$

Furthermore, every $\lambda \in \mathfrak{A}$ satisfies

$$s_\lambda\left(x_1, x_2, \ldots, x_k\right) = \left(x_1 x_2 \cdots x_k\right)^{m+n} \cdot s_{\lambda^{\vee\{m+n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right). \qquad (13.92.14)$$

[735]

Now, (13.92.7) yields

$$\begin{aligned} &\sum_{\lambda \in \mathfrak{A}} c^{\lambda}_{\mu,\nu} s_\lambda\left(x_1, x_2, \ldots, x_k\right) \\ &= \underbrace{s_\mu\left(x_1, x_2, \ldots, x_k\right)}_{\substack{=\left(x_1 x_2 \cdots x_k\right)^m \cdot s_{\mu^{\vee\{m\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \\ \text{(by (13.92.12))}}} \cdot \underbrace{s_\nu\left(x_1, x_2, \ldots, x_k\right)}_{\substack{=\left(x_1 x_2 \cdots x_k\right)^n \cdot s_{\nu^{\vee\{n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \\ \text{(by (13.92.13))}}} \\ &= \left(x_1 x_2 \cdots x_k\right)^m \cdot s_{\mu^{\vee\{m\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \cdot \left(x_1 x_2 \cdots x_k\right)^n \cdot s_{\nu^{\vee\{n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \\ &= \underbrace{\left(x_1 x_2 \cdots x_k\right)^m \left(x_1 x_2 \cdots x_k\right)^n}_{=\left(x_1 x_2 \cdots x_k\right)^{m+n}} \cdot \underbrace{s_{\mu^{\vee\{m\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \cdot s_{\nu^{\vee\{n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right)}_{\substack{=\sum_{\lambda \in \mathfrak{A}} c^{\lambda^{\vee\{m+n\}}}_{\mu^{\vee\{m\}}, \nu^{\vee\{n\}}} s_{\lambda^{\vee\{m+n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \\ \text{(by (13.92.11))}}} \\ &= \left(x_1 x_2 \cdots x_k\right)^{m+n} \cdot \sum_{\lambda \in \mathfrak{A}} c^{\lambda^{\vee\{m+n\}}}_{\mu^{\vee\{m\}}, \nu^{\vee\{n\}}} s_{\lambda^{\vee\{m+n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right) \\ &= \sum_{\lambda \in \mathfrak{A}} c^{\lambda^{\vee\{m+n\}}}_{\mu^{\vee\{m\}}, \nu^{\vee\{n\}}} \underbrace{\left(x_1 x_2 \cdots x_k\right)^{m+n} \cdot s_{\lambda^{\vee\{m+n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right)}_{\substack{=s_\lambda\left(x_1, x_2, \ldots, x_k\right) \\ \text{(by (13.92.14))}}} \\ &= \sum_{\lambda \in \mathfrak{A}} c^{\lambda^{\vee\{m+n\}}}_{\mu^{\vee\{m\}}, \nu^{\vee\{n\}}} s_\lambda\left(x_1, x_2, \ldots, x_k\right). \qquad (13.92.15) \end{aligned}$$

[735] *Proof of (13.92.14):* Let $\lambda \in \mathfrak{A}$. Then, $\lambda \in \mathfrak{A} = \{\alpha \in \operatorname{Par} \mid \ell(\alpha) \leq k;\text{ all parts of } \alpha \text{ are } \leq m+n\}$. In other words, λ is an element of Par such that $\ell(\lambda) \leq k$ and such that all parts of λ are $\leq m+n$. Now, (13.92.6) yields that $\lambda^{\vee\{m+n\}} \in \mathfrak{A} = \{\alpha \in \operatorname{Par} \mid \ell(\alpha) \leq k;\text{ all parts of } \alpha \text{ are } \leq m+n\}$. In other words, $\lambda^{\vee\{m+n\}}$ is an element of Par such that $\ell\left(\lambda^{\vee\{m+n\}}\right) \leq k$ and such that all parts of $\lambda^{\vee\{m+n\}}$ are $\leq m+n$.

Recall that $\left(\lambda^{\vee\{m+n\}}\right)^{\vee\{m+n\}} = \lambda$ (as we said, this follows easily from the definitions). Thus,

$$\lambda = \left(\lambda^{\vee\{m+n\}}\right)^{\vee\{m+n\}} = \left(m+n-\left(\lambda^{\vee\{m+n\}}\right)_k, m+n-\left(\lambda^{\vee\{m+n\}}\right)_{k-1}, \ldots, m+n-\left(\lambda^{\vee\{m+n\}}\right)_1\right)$$

(by the definition of $\left(\lambda^{\vee\{m+n\}}\right)^{\vee\{m+n\}}$). Hence, we can apply Exercise 2.9.15(d) to $m+n$, $\lambda^{\vee\{m+n\}}$, $\lambda^{\vee\{m+n\}}$, λ and λ instead of m, λ, μ, $\lambda^\vee$ and $\mu^\vee$. As a result, we obtain

$$s_\lambda\left(x_1, x_2, \ldots, x_k\right) = \left(x_1 x_2 \cdots x_k\right)^{m+n} \cdot s_{\lambda^{\vee\{m+n\}}}\left(x_1^{-1}, x_2^{-1}, \ldots, x_k^{-1}\right).$$

This proves (13.92.14).

But Remark 2.3.9(d) (applied to $N = k$) yields that the set $\{s_\lambda(x_1, x_2, \ldots, x_k)\}$, as λ runs through all partitions having length $\leq k$, is a basis of the $\mathbf{k}$-module $\Lambda(x_1, x_2, \ldots, x_k)$. In other words, the family $(s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \operatorname{Par};\ \ell(\lambda) \leq k}$ is a basis of the $\mathbf{k}$-module $\Lambda(x_1, x_2, \ldots, x_k)$. In particular, the family $(s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \operatorname{Par};\ \ell(\lambda) \leq k}$ is $\mathbf{k}$-linearly independent.

But the set $\mathfrak{A}$ is a subset of $\{\alpha \in \operatorname{Par} \mid \ell(\alpha) \leq k\}$. Hence, the family $(s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \mathfrak{A}}$ is a subfamily of the family $(s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \{\alpha \in \operatorname{Par} \mid \ell(\alpha) \leq k\}} = (s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \operatorname{Par};\ \ell(\lambda) \leq k}$. Since the family $(s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \operatorname{Par};\ \ell(\lambda) \leq k}$ is $\mathbf{k}$-linearly independent, we thus conclude that its subfamily $(s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \mathfrak{A}}$ is also $\mathbf{k}$-linearly independent. As a consequence, if two $\mathbf{k}$-linear combinations of the family $(s_\lambda(x_1, x_2, \ldots, x_k))_{\lambda \in \mathfrak{A}}$ are equal, then their respective coefficients must be equal. Thus, from (13.92.16), we conclude that

$$c^{\lambda}_{\mu,\nu} = c^{\lambda^{\vee\{m+n\}}}_{\mu^{\vee\{m\}},\nu^{\vee\{n\}}} \qquad \text{for every } \lambda \in \mathfrak{A}. \tag{13.92.16}$$

Now, let λ be a partition such that $\ell(\lambda) \leq k$. Assume that all parts of λ are $\leq m+n$. Then, λ is an element of Par such that $\ell(\lambda) \leq k$ and such that all parts of λ are $\leq m+n$. In other words, $\lambda \in \mathfrak{A}$ (by the definition of $\mathfrak{A}$). Hence, (13.92.16) yields $c^{\lambda}_{\mu,\nu} = c^{\lambda^{\vee\{m+n\}}}_{\mu^{\vee\{m\}},\nu^{\vee\{n\}}}$. This solves Exercise 2.9.16(c).

13.93. **Solution to Exercise 2.9.17.** *Solution to Exercise 2.9.17.* (a) We notice that every partition λ and every positive integer i satisfy

$$\begin{aligned}\left(\lambda^t\right)_i &= |\{j \in \{1,2,3,\ldots\} \mid \lambda_j \geq i\}| \qquad (\text{by } (2.2.7)) \\ &= |\{j \in \{1,2,\ldots,\ell(\lambda)\} \mid \lambda_j \geq i\}| \end{aligned} \tag{13.93.1}$$

(because $\lambda_j \geq i$ can happen only when $j \in \{1,2,\ldots,\ell(\lambda)\}$ (since i is positive)).

Let μ and ν be two partitions. For every positive integer i, we have

$$\begin{aligned}\left((\mu \sqcup \nu)^t\right)_i &= \left|\left\{j \in \{1,2,\ldots,\ell(\mu \sqcup \nu)\} \mid (\mu \sqcup \nu)_j \geq i\right\}\right| \qquad (\text{by } (13.93.1), \text{ applied to } \lambda = \mu \sqcup \nu) \\ &= (\text{the number of entries of } \mu \sqcup \nu \text{ which are } \geq i) \\ &= \left(\text{the number of entries of the list } \left(\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}, \nu_1, \nu_2, \ldots, \nu_{\ell(\nu)}\right) \text{ which are } \geq i\right) \\ &\qquad \left(\begin{array}{c}\text{since } \mu \sqcup \nu \text{ is the result of sorting the list } \left(\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}, \nu_1, \nu_2, \ldots, \nu_{\ell(\nu)}\right) \\ \text{in decreasing order, and clearly the procedure of sorting does not change} \\ \text{the number of entries of the list which are } \geq i\end{array}\right) \\ &= \underbrace{\left(\text{the number of entries of the list } \left(\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}\right) \text{ which are } \geq i\right)}_{\substack{=|\{j \in \{1,2,\ldots,\ell(\mu)\} \mid \mu_j \geq i\}| = \left(\mu^t\right)_i \\ (\text{by } (13.93.1), \text{ applied to } \lambda = \mu)}} \\ &\qquad + \underbrace{\left(\text{the number of entries of the list } \left(\nu_1, \nu_2, \ldots, \nu_{\ell(\nu)}\right) \text{ which are } \geq i\right)}_{\substack{=|\{j \in \{1,2,\ldots,\ell(\nu)\} \mid \nu_j \geq i\}| = \left(\nu^t\right)_i \\ (\text{by } (13.93.1), \text{ applied to } \lambda = \nu)}} \\ &= \left(\mu^t\right)_i + \left(\nu^t\right)_i = \left(\mu^t + \nu^t\right)_i\end{aligned}$$

(since the definition of $\mu^t + \nu^t$ yields $\left(\mu^t + \nu^t\right)_i = \left(\mu^t\right)_i + \left(\nu^t\right)_i$). In other words,

$$(\mu \sqcup \nu)^t = \mu^t + \nu^t. \tag{13.93.2}$$

Applying this to μ^t and ν^t instead of μ and ν, we obtain $\left(\mu^t \sqcup \nu^t\right)^t = \underbrace{\left(\mu^t\right)^t}_{=\mu} + \underbrace{\left(\nu^t\right)^t}_{=\nu} = \mu + \nu$, so that $\mu + \nu = \left(\mu^t \sqcup \nu^t\right)^t$ and thus

$$\left(\underbrace{\mu + \nu}_{=\left(\mu^t \sqcup \nu^t\right)^t}\right)^t = \left(\left(\mu^t \sqcup \nu^t\right)^t\right)^t = \mu^t \sqcup \nu^t.$$

This solves Exercise 2.9.17(a).

(b) Let μ and ν be two partitions. We are going to prove that $c^{\mu+\nu}_{\mu,\nu} = 1$.

A $(\mu+\nu,\mu,\nu)$-*LR-tableau* will mean a column-strict tableau T of shape $(\mu+\nu)/\mu$ with $\operatorname{cont}(T)=\nu$ having the property that each $\operatorname{cont}(T|_{\operatorname{cols}\geq j})$ is a partition (where we are using the notations of Corollary 2.6.12). Corollary 2.6.12 shows that $c^{\mu+\nu}_{\mu,\nu}$ is the number of $(\mu+\nu,\mu,\nu)$-LR-tableaux. Hence, in order to prove that $c^{\mu+\nu}_{\mu,\nu}=1$, it will be enough to show that there exists one and only one $(\mu+\nu,\mu,\nu)$-LR-tableau.

First of all, let T_0 be the filling of the skew shape $(\mu+\nu)/\mu$ which assigns to every cell in row i the number i, for all $i\in\{1,2,3,...\}$. This T_0 is clearly a column-strict tableau, and satisfies $\operatorname{cont}(T_0)=\nu$ (because for every positive integer i, the i-th row of the skew shape $(\mu+\nu)/\mu$ has $\underbrace{(\mu+\nu)_i}_{=\mu_i+\nu_i}-\mu_i=(\mu_i+\nu_i)-\mu_i=\nu_i$ cells). Moreover, for every $j\in\{1,2,3,...\}$, the weak composition $\operatorname{cont}(T_0|_{\operatorname{cols}\geq j})$ is a partition[736]. Therefore, T_0 is a $(\mu+\nu,\mu,\nu)$-LR-tableau. It remains to prove that it is the only $(\mu+\nu,\mu,\nu)$-LR-tableau.

So fix any $(\mu+\nu,\mu,\nu)$-LR-tableau T. Thus, T is a column-strict tableau of shape $(\mu+\nu)/\mu$ with $\operatorname{cont}(T)=\nu$ having the property that each $\operatorname{cont}(T|_{\operatorname{cols}\geq j})$ is a partition.

We shall show that

$$\text{for every } i\in\{1,2,3,...\}\text{, all entries in the } i\text{-th row of } T \text{ are } \leq i. \tag{13.93.3}$$

Proof of (13.93.3): Assume the contrary. Then, there exists an $i\in\{1,2,3,...\}$ such that not all entries in the i-th row of T are $\leq i$. Let p be the **smallest** such i (this is clearly well-defined). Hence, not all entries in the p-th row of T are $\leq p$. But since p is minimal, we know that (13.93.3) holds for every $i<p$.

Not all entries in the p-th row of T are $\leq p$. In other words, at least one entry of the p-th row of T must be $>p$. Since the entries of T weakly increase along rows, this yields that the rightmost entry of the p-th row of T is $>p$. Let q be this entry, and let j be the column in which the rightmost cell of the p-th row of T lies. Thus, q is the entry in cell (p,j) of T. Therefore, the entry q appears in the tableau $T|_{\operatorname{cols}\geq j}$. Hence, $\operatorname{cont}(T|_{\operatorname{cols}\geq j})_q\geq 1$. Note that $q>p$ (by the definition of q).

We know that $\operatorname{cont}(T|_{\operatorname{cols}\geq j})$ is a partition, so that

$$\begin{aligned}(\operatorname{cont}(T|_{\operatorname{cols}\geq j}))_p &\geq \operatorname{cont}(T|_{\operatorname{cols}\geq j})_q \qquad (\text{since } p<q)\\ &\geq 1.\end{aligned}$$

In other words, the entry p appears somewhere in the tableau $T|_{\operatorname{cols}\geq j}$. Where can it appear? It cannot appear in any of the first $p-1$ rows, because all entries in these rows are $<p$ (since (13.93.3) holds for every $i<p$). Hence, it must appear in the p-th row or further down. In other words, this entry p appears in a cell (u,v) of T with $u\geq p$ and $v\geq j$. As a consequence, this entry p is $\geq$ to the entry in cell (p,j) of T (since T is column-strict). Since the entry in cell (p,j) of T is q, this yields $p\geq q$, which contradicts $q>p$. This contradiction shows that our assumption was wrong, and (13.93.3) is proven.

We furthermore claim that

$$\text{for every } i\in\{1,2,3,...\}\text{, all entries in the } i\text{-th row of } T \text{ are } i. \tag{13.93.4}$$

Proof of (13.93.4): Assume the contrary. Then, there exists an $i\in\{1,2,3,...\}$ such that not all entries in the i-th row of T are i. Let p be the **smallest** such i (this is clearly well-defined). Hence, not all entries in the p-th row of T are p. But since p is minimal, we know that (13.93.4) holds for every $i<p$.

All entries in the p-th row of T are $\leq p$ (by (13.93.3)), but not all of them are p. Hence, the p-th row of T has an entry $<p$. Let k be this entry. Thus, $k<p$. We can apply (13.93.4) to $i=k$ (since (13.93.4) holds for every $i<p$), and conclude that all entries in the k-th row of T are k. Thus, in the tableau T, the entry k appears ν_k times in row k (since the length of the k-th row of T is $\underbrace{(\mu+\nu)_k}_{=\mu_k+\nu_k}-\mu_k=(\mu_k+\nu_k)-\mu_k=\nu_k$) and at least 1 time in row p (by the definition of k). In total, k must thus appear at least ν_k+1 times in T, which contradicts the fact that $\operatorname{cont}(T)=\nu$. This contradiction disproves our assumption, and thus (13.93.4) is proven.

[736] *Proof.* In fact, fix $j\in\{1,2,3,...\}$. Then, both ν_i and μ_i decrease with $i\in\{1,2,3,...\}$ (since ν and μ are partitions), and thus $\min\{\mu_i,j\}$ also decreases with $i\in\{1,2,3,...\}$.

Now, for every $i\in\{1,2,3,...\}$, the i-th entry of $\operatorname{cont}(T_0|_{\operatorname{cols}\geq j})$ is the number of boxes in columns $j,j+1,j+2,...$ of the i-th row of the skew shape $(\mu+\nu)/\mu$. This number is easily seen to be $\underbrace{(\mu+\nu)_i}_{=\mu_i+\nu_i}-\underbrace{\max\{\mu_i,j\}}_{=\mu_i+j-\min\{\mu_i,j\}}=\mu_i+\nu_i-(\mu_i+j-\min\{\mu_i,j\})=\nu_i-j+\min\{\mu_i,j\}$, and therefore decreases with i (because both ν_i and $\min\{\mu_i,j\}$ decrease with i). Hence, $\operatorname{cont}(T_0|_{\operatorname{cols}\geq j})$ is a partition, qed.

Now that (13.93.4) is proven, we immediately conclude that $T = T_0$. Now, forget that we fixed T. We thus have shown that every $(\mu+\nu,\mu,\nu)$-LR-tableau T equals T_0. Hence, there exists one and only one $(\mu+\nu,\mu,\nu)$-LR-tableau, namely $T = T_0$ (because we have already seen that T_0 is a $(\mu+\nu,\mu,\nu)$-LR-tableau). As we said above, this proves that

$$c_{\mu,\nu}^{\mu+\nu} = 1. \tag{13.93.5}$$

It remains to show that $c_{\mu,\nu}^{\mu\sqcup\nu} = 1$. Exercise 2.7.11(c) (applied to $\lambda = \mu\sqcup\nu$) shows that

$$\begin{aligned} c_{\mu,\nu}^{\mu\sqcup\nu} &= c_{\mu^t,\nu^t}^{(\mu\sqcup\nu)^t} = c_{\mu^t,\nu^t}^{\mu^t+\nu^t} \qquad \left(\text{since } (\mu\sqcup\nu)^t = \mu^t+\nu^t \text{ (by Exercise 2.9.17(a))}\right) \\ &= 1 \qquad \left(\text{by (13.93.5), applied to } \mu^t \text{ and } \nu^t \text{ instead of } \mu \text{ and } \nu\right). \end{aligned}$$

This solves Exercise 2.9.17(b).

(c) Let $k \in \mathbb{N}$ and $n \in \mathbb{N}$ satisfy $k \le n$, and let $\mu \in \operatorname{Par}_k$, $\nu \in \operatorname{Par}_{n-k}$ and $\lambda \in \operatorname{Par}_n$ be such that $c_{\mu,\nu}^{\lambda} \neq 0$. We need to prove that $\mu+\nu \trianglerighteq \lambda \trianglerighteq \mu\sqcup\nu$.

We have $|\lambda| = n$, $|\mu| = k$ and $|\nu| = n-k$, so that $|\lambda| = n = \underbrace{k}_{=|\mu|} + \underbrace{(n-k)}_{=|\nu|} = |\mu|+|\nu|$. We will first show that

$$\mu+\nu \trianglerighteq \lambda. \tag{13.93.6}$$

A (λ,μ,ν)-*LR-tableau* will mean a column-strict tableau T of shape λ/μ with $\operatorname{cont}(T) = \nu$ having the property that each $\operatorname{cont}(T|_{\text{cols}\ge j})$ is a partition (where we are using the notations of Corollary 2.6.12). Corollary 2.6.12 shows that $c_{\mu,\nu}^{\lambda}$ is the number of (λ,μ,ν)-LR-tableaux. Since $c_{\mu,\nu}^{\lambda} \neq 0$, we thus see that there exists at least one (λ,μ,ν)-LR-tableau. Let this (λ,μ,ν)-LR-tableau be T.

Just as in the solution of Exercise 2.9.17(b), we can prove that (13.93.3) holds. Let k be a positive integer. Applying (13.93.3) to all $i \in \{1,2,...,k\}$, we see that all entries in the first k rows of T (meaning the 1-st row, the 2-nd row, etc., the k-th row) are $\le k$. Hence,

$$\begin{aligned} &(\text{the number of all entries in the first } k \text{ rows of } T) \\ &\le (\text{the number of all entries } \le k \text{ in } T) = \sum_{i=1}^{k} \underbrace{(\text{the number of all entries } i \text{ in } T)}_{\substack{=(\operatorname{cont} T)_i = \nu_i \\ (\text{since } \operatorname{cont} T = \nu)}} = \sum_{i=1}^{k} \nu_i. \end{aligned}$$

Since

$$\begin{aligned} &(\text{the number of all entries in the first } k \text{ rows of } T) \\ &= \sum_{i=1}^{k} \underbrace{(\text{the number of all entries in the } i\text{-th row of } T)}_{=\lambda_i-\mu_i} = \sum_{i=1}^{k} (\lambda_i-\mu_i) = \sum_{i=1}^{k} \lambda_i - \sum_{i=1}^{k} \mu_i, \end{aligned}$$

this rewrites as $\sum_{i=1}^{k} \lambda_i - \sum_{i=1}^{k} \mu_i \le \sum_{i=1}^{k} \nu_i$. Hence,

$$\sum_{i=1}^{k} \lambda_i \le \sum_{i=1}^{k} \mu_i + \sum_{i=1}^{k} \nu_i = \sum_{i=1}^{k} \underbrace{(\mu_i+\nu_i)}_{=(\mu+\nu)_i} = \sum_{i=1}^{k} (\mu+\nu)_i\,,$$

so that $\sum_{i=1}^{k} (\mu+\nu)_i \ge \sum_{i=1}^{k} \lambda_i$. In other words, $(\mu+\nu)_1 + (\mu+\nu)_2 + \cdots + (\mu+\nu)_k \ge \lambda_1+\lambda_2+\cdots+\lambda_k$.

Now, let us forget that we fixed k. We have shown that $(\mu+\nu)_1 + (\mu+\nu)_2 + \cdots + (\mu+\nu)_k \ge \lambda_1+\lambda_2+\cdots+\lambda_k$ for every positive integer k. Combined with $|\lambda| = |\mu|+|\nu| = |\mu+\nu|$, this yields that $\mu+\nu \trianglerighteq \lambda$. This proves (13.93.6).

It now remains to prove that $\lambda \trianglerighteq \mu\sqcup\nu$. To do so, we notice that Exercise 2.7.11(c) yields $c_{\mu,\nu}^{\lambda} = c_{\mu^t,\nu^t}^{\lambda^t}$, so that $c_{\mu^t,\nu^t}^{\lambda^t} = c_{\mu,\nu}^{\lambda} \neq 0$. Hence, we can apply (13.93.6) to λ^t, μ^t and ν^t instead of λ, μ and ν. As a result, we obtain $\mu^t+\nu^t \trianglerighteq \lambda^t$. Since $(\mu\sqcup\nu)^t = \mu^t+\nu^t$ (by Exercise 2.9.17(a)), this rewrites as $(\mu\sqcup\nu)^t \trianglerighteq \lambda^t$. But Exercise 2.2.9 (applied to $\mu\sqcup\nu$ instead of μ) yields that $\lambda \trianglerighteq \mu\sqcup\nu$ if and only if $(\mu\sqcup\nu)^t \trianglerighteq \lambda^t$. Since we already know that $(\mu\sqcup\nu)^t \trianglerighteq \lambda^t$, we can thus conclude that $\lambda \trianglerighteq \mu\sqcup\nu$. Combined with (13.93.6), this yields $\mu+\nu \trianglerighteq \lambda \trianglerighteq \mu\sqcup\nu$. This solves Exercise 2.9.17(c).

(d) Let $n \in \mathbb{N}$ and $m \in \mathbb{N}$ and $\alpha, \beta \in \operatorname{Par}_n$ and $\gamma, \delta \in \operatorname{Par}_m$ be such that $\alpha \rhd \beta$ and $\gamma \rhd \delta$. It is completely straightforward to check that

$$\alpha + \gamma \rhd \beta + \delta \tag{13.93.7}$$

[737]. It remains to prove that $\alpha \sqcup \gamma \rhd \beta \sqcup \delta$.

Exercise 2.2.9 (applied to $\lambda = \alpha$ and $\mu = \beta$) yields that $\alpha \rhd \beta$ if and only if $\beta^t \rhd \alpha^t$. Since $\alpha \rhd \beta$, we thus have $\beta^t \rhd \alpha^t$. Similarly, $\delta^t \rhd \gamma^t$. Hence, we can apply (13.93.7) to β^t, α^t, δ^t and γ^t instead of α, β, γ and δ. As a result, we obtain $\beta^t + \delta^t \rhd \alpha^t + \gamma^t$. Now, (13.93.2) (applied to $\mu = \beta$ and $\nu = \delta$) yields $(\beta \sqcup \delta)^t = \beta^t + \delta^t$. Similarly, $(\alpha \sqcup \gamma)^t = \alpha^t + \gamma^t$. Thus, $(\beta \sqcup \delta)^t = \beta^t + \delta^t \rhd \alpha^t + \gamma^t = (\alpha \sqcup \gamma)^t$.

Finally, Exercise 2.2.9 (applied to $n+m$, $\alpha \sqcup \gamma$ and $\beta \sqcup \delta$ instead of n, λ and μ) yields that $\alpha \sqcup \gamma \rhd \beta \sqcup \delta$ if and only if $(\beta \sqcup \delta)^t \rhd (\alpha \sqcup \gamma)^t$. Since we have $(\beta \sqcup \delta)^t \rhd (\alpha \sqcup \gamma)^t$, we thus obtain $\alpha \sqcup \gamma \rhd \beta \sqcup \delta$. This completes the solution of Exercise 2.9.17(d).

(e) The Ferrers diagram of the partition $\lambda = (m^k)$ is a rectangle. Let C denote the center of this rectangle. For every partition μ satisfying $\mu \subseteq \lambda$, let us define a partition μ^c by $\mu^c = (m - \mu_k, m - \mu_{k-1}, ..., m - \mu_1)$ [738]. The Ferrers diagram of this partition μ^c is obtained from the skew Ferrers diagram of the skew partition [739] λ/μ by the 180° rotation around C. In other words, the skew Ferrers diagram of $\mu^c/\varnothing$ is obtained from the skew Ferrers diagram of the skew partition λ/μ by the 180° rotation around C. Hence, Exercise 2.3.4(b) (applied to $\lambda' = \mu^c$ and $\mu' = \varnothing$) yields that

$$s_{\lambda/\mu} = s_{\mu^c/\varnothing} = s_{\mu^c}. \tag{13.93.8}$$

Now, Proposition 2.3.6(iv) yields

$$\Delta s_\lambda = \sum_{\mu \subseteq \lambda} s_\mu \otimes \underbrace{s_{\lambda/\mu}}_{\substack{=s_{\mu^c} \\ \text{(by (13.93.8))}}} = \sum_{\mu \subseteq \lambda} s_\mu \otimes s_{\mu^c}.$$

Compared with

$$\Delta s_\lambda = \sum_{\mu,\nu} \underbrace{\hat{c}^\lambda_{\mu,\nu}}_{=c^\lambda_{\mu,\nu}} s_\mu \otimes s_\nu \qquad \text{(by (2.5.7))}$$
$$= \sum_{\mu,\nu} c^\lambda_{\mu,\nu} s_\mu \otimes s_\nu,$$

this yields $\sum_{\mu,\nu} c^\lambda_{\mu,\nu} s_\mu \otimes s_\nu = \sum_{\mu \subseteq \lambda} s_\mu \otimes s_{\mu^c}$. Comparing the coefficients in front of $s_\mu \otimes s_\nu$ on both sides of this equality, we obtain: Any two partitions μ and ν satisfy

$$c^\lambda_{\mu,\nu} = \begin{cases} 1, & \text{if } \mu \subseteq \lambda \text{ and } \nu = \mu^c; \\ 0, & \text{otherwise} \end{cases} \in \{0, 1\}.$$

This solves Exercise 2.9.17(e).

(f) We know that $(s_\mu)_{\mu \in \operatorname{Par}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, $(s_\mu \otimes s_\nu)_{\mu,\nu \in \operatorname{Par}}$ is a basis of the $\mathbf{k}$-module $\Lambda \otimes \Lambda$. We will refer to this basis as the *Schur basis* of $\Lambda \otimes \Lambda$.

The equality (2.5.7) yields

$$\Delta s_\lambda = \sum_{\mu,\nu} \underbrace{\hat{c}^\lambda_{\mu,\nu}}_{=c^\lambda_{\mu,\nu}} s_\mu \otimes s_\nu = \sum_{\mu,\nu} c^\lambda_{\mu,\nu} s_\mu \otimes s_\nu.$$

Thus, for every $\mu, \nu \in \operatorname{Par}$, the $s_\mu \otimes s_\nu$-coefficient of Δs_λ with respect to the Schur basis of $\Lambda \otimes \Lambda$ is $c^\lambda_{\mu,\nu}$.

But $\lambda = (a+1, 1^b)$. Hence, Exercise 2.9.14(d) gives a formula for $\Delta s_\lambda = \Delta s_{(a+1,1^b)}$ as a sum of pure tensors of the form $s_\mu \otimes s_\nu$ with $\mu, \nu \in \operatorname{Par}$. Every such pure tensor occurs **at most once** in this formula (as can be easily verified). In other words, for every $\mu, \nu \in \operatorname{Par}$, the $s_\mu \otimes s_\nu$-coefficient of Δs_λ with respect

[737] To prove this, just recall how $\alpha + \gamma$ and $\beta + \delta$ are defined, and recall that two partitions $\lambda, \mu \in \operatorname{Par}_n$ satisfy $\lambda \rhd \mu$ if and only if we have $(\lambda_1 + \lambda_2 + \cdots + \lambda_k \geq \mu_1 + \mu_2 + \cdots + \mu_k$ for every positive integer $k)$.

[738] This is well-defined, since every $i \in \{1, 2, ..., k\}$ satisfies $\mu_i \leq m$ (because $\mu \subseteq \lambda = (m^k)$).

[739] A *skew partition* shall mean a pair (α, β) of partitions satisfying $\beta \subseteq \alpha$. We write such a skew partition (α, β) as α/β. For every skew partition α/β, we define the skew Ferrers diagram $Y(\alpha/\beta)$ of α/β by $Y(\alpha/\beta) = Y(\alpha) \setminus Y(\beta)$, where $Y(\kappa)$ means the Ferrers diagram of a partition κ.

to the Schur basis of $\Lambda \otimes \Lambda$ is either 0 or 1. Since the $s_\mu \otimes s_\nu$-coefficient of Δs_λ with respect to the Schur basis of $\Lambda \otimes \Lambda$ is $c^\lambda_{\mu,\nu}$, this rewrites as follows: For every $\mu, \nu \in \operatorname{Par}$, the scalar $c^\lambda_{\mu,\nu}$ is either 0 or 1. This solves Exercise 2.9.17(f).

(g) The following solution is inspired by [211, proof of Thm. 2.1(iv)].

Before we start with the solution, we recall two formulas. Firstly, any two partitions μ and ν satisfy

$$\begin{aligned} s_\mu s_\nu &= \sum_{\lambda \in \operatorname{Par}} c^\lambda_{\mu,\nu} s_\lambda && \text{(this is just a restatement of (2.5.6))} \\ &= \sum_{\tau \in \operatorname{Par}} c^\tau_{\mu,\nu} s_\tau && \text{(here, we renamed the summation index } \lambda \text{ as } \tau\text{)} . \end{aligned} \tag{13.93.9}$$

Secondly, any two partitions λ and μ satisfy

$$\begin{aligned} s_{\lambda/\mu} &= \sum_{\nu \in \operatorname{Par}} c^\lambda_{\mu,\nu} s_\nu && \text{(this is one of the identities in Remark 2.5.9)} \\ &= \sum_{\tau \in \operatorname{Par}} c^\lambda_{\mu,\tau} s_\tau && \text{(here, we renamed the summation index } \nu \text{ as } \tau\text{)} . \end{aligned} \tag{13.93.10}$$

Now, let λ be any partition, and let μ and ν be two rectangular partitions. We need to show that $c^\lambda_{\mu,\nu} \in \{0,1\}$.

Assume the contrary. Thus, $c^\lambda_{\mu,\nu} \notin \{0,1\}$, so that $c^\lambda_{\mu,\nu} \neq 0$.

We have $c^\lambda_{\mu,\nu} = c^\lambda_{\nu,\mu}$. Hence, we can WLOG assume that $\ell(\mu) \geq \ell(\nu)$ (since otherwise, we can just switch μ and ν). Assume this. Assume WLOG that $\mu \neq \varnothing$ (since otherwise, $\mu = \varnothing$ and thus $\nu = \varnothing$ (because $\ell(\mu) \geq \ell(\nu)$), which makes the claim $c^\lambda_{\mu,\nu} \in \{0,1\}$ a rather obvious fact).

The partition μ is rectangular, i.e., has the form $\left(m^k\right) = \left(\underbrace{m, m, \ldots, m}_{k \text{ times}}\right)$ for some $m \in \mathbb{N}$ and $k \in \mathbb{N}$. Consider these m and k. Both m and k are positive (since $\left(m^k\right) = \mu \neq \varnothing$). Thus, $k = \ell(\mu)$ (since $\mu = \left(m^k\right)$), so that $k = \ell(\mu) \geq \ell(\nu)$, thus $\ell(\nu) \leq k$.

Corollary 2.6.12 shows that $c^\lambda_{\mu,\nu}$ counts column-strict tableaux T of shape λ/μ with $\operatorname{cont}(T) = \nu$ having the property that each $\operatorname{cont}(T|_{\operatorname{cols} \geq j})$ is a partition (where we are using the notations of Corollary 2.6.12). Since $c^\lambda_{\mu,\nu} \neq 0$, we see that there exists at least one such tableau T. Consider this T. All entries of the tableau T are $\leq \ell(\nu)$ (because $\operatorname{cont}(T) = \nu$). This quickly yields that $\mu_k \geq \lambda_{k+1}$ [740]. Of course, we also have $\mu \subseteq \lambda$ (since T is a tableau of shape λ/μ), and thus $\lambda_i \geq \mu_i$ for every $i \in \{1,2,3,\ldots\}$. In particular, every $i \in \{1,2,\ldots,k\}$ satisfies $\lambda_i \geq \mu_i = m$ (since $\mu = \left(m^k\right)$).

Now, define F, $F_{\text{rows} \leq k}$ and $F_{\text{rows} > k}$ as in Exercise 2.3.5. Define four partitions α, β, γ and δ by

$$\alpha = (\lambda_1 - m, \lambda_2 - m, \ldots, \lambda_k - m), \qquad \beta = \varnothing,$$
$$\gamma = (\lambda_{k+1}, \lambda_{k+2}, \lambda_{k+3}, \ldots), \qquad \delta = \varnothing$$

(notice that α is well-defined because every $i \in \{1,2,\ldots,k\}$ satisfies $\lambda_i \geq m$). It is now easy to see that the skew Ferrers diagram α/β can be obtained from $F_{\text{rows} \leq k}$ by parallel translation (namely, the translation by m steps to the west), and that the skew Ferrers diagram γ/δ can be obtained from $F_{\text{rows} > k}$ by parallel

[740] *Proof.* Assume the contrary. Thus, $\mu_k < \lambda_{k+1}$. Since $\mu = \left(m^k\right)$, we have $\mu_k = m$, so that $m = \mu_k < \lambda_{k+1}$. Thus, $m \leq \lambda_{k+1} - 1$ (since m and λ_{k+1} are integers), so that $m + 1 \leq \lambda_{k+1}$. Now, for every $i \in \{1,2,\ldots,k+1\}$, we have

$$\begin{aligned} \mu_i &\leq m && \left(\text{since } \mu = \left(m^k\right)\right) \\ &< m + 1 \leq \lambda_{k+1} \leq \lambda_i && (\text{since } k+1 \geq i) . \end{aligned}$$

Hence, $(i, m+1)$ is a cell of the skew Ferrers diagram λ/μ for every $i \in \{1,2,\ldots,k+1\}$. Altogether, the $(m+1)$-th column of the skew Ferrers diagram λ/μ contains at least $k+1$ different cells (namely, the cells $(i, m+1)$ for all $i \in \{1,2,\ldots,k+1\}$). In the tableau T, these $k+1$ different cells must be filled with $k+1$ distinct values (because the entries of T are strictly decreasing top-to-bottom in columns). As a consequence, there must be at least $k+1$ distinct values among the entries of T; but this is impossible, because all entries of T are $\leq \ell(\nu) \leq k$. This contradiction proves that our assumption was wrong, qed.

translation (namely, the translation by k steps to the north). Hence, Exercise 2.3.5 yields

$$\begin{aligned} s_{\lambda/\mu} &= s_{\alpha/\beta} s_{\gamma/\delta} = \underbrace{s_{\alpha/\varnothing}}_{=s_\alpha} \underbrace{s_{\gamma/\varnothing}}_{=s_\gamma} \qquad (\text{since } \beta = \varnothing \text{ and } \delta = \varnothing) \\ &= s_\alpha s_\gamma = \sum_{\tau \in \operatorname{Par}} c^{\tau}_{\alpha,\gamma} s_\tau \qquad (\text{by (13.93.9)}) . \end{aligned}$$

Compared with (13.93.10), this yields $\sum_{\tau \in \operatorname{Par}} c^{\lambda}_{\mu,\tau} s_\tau = \sum_{\tau \in \operatorname{Par}} c^{\tau}_{\alpha,\gamma} s_\tau$. Since $(s_\tau)_{\tau \in \operatorname{Par}}$ is a $\mathbf{k}$-basis of Λ, we can compare coefficients before s_ν in this equality, and thus obtain $c^{\lambda}_{\mu,\nu} = c^{\nu}_{\alpha,\gamma}$. But ν is a rectangular partition, and thus has the form $\left(\widetilde{m}^{\widetilde{k}}\right)$ for some $\widetilde{m} \in \mathbb{N}$ and $\widetilde{k} \in \mathbb{N}$. Hence, $c^{\nu}_{\alpha,\gamma} \in \{0, 1\}$ (by Exercise 2.9.17(e), applied to $\widetilde{m}$, $\widetilde{k}$, ν, α and γ instead of m, k, λ, μ and ν). Thus, $c^{\lambda}_{\mu,\nu} = c^{\nu}_{\alpha,\gamma} \in \{0, 1\}$, which contradicts $c^{\lambda}_{\mu,\nu} \notin \{0, 1\}$. This contradiction proves that our assumption was wrong, and Exercise 2.9.17(g) is solved.

13.94. **Solution to Exercise 2.9.18.** *Solution to Exercise 2.9.18.* (a) We shall prove the implications $\mathcal{A} \Longrightarrow \mathcal{B}$ and $\mathcal{B} \Longrightarrow \mathcal{A}$.

Proof of the implication $\mathcal{A} \Longrightarrow \mathcal{B}$: Assume that Assertion $\mathcal{A}$ holds. That is, there exist a partition λ and a column-strict tableau T of shape λ/μ such that all $(i, j) \in \{1, 2, 3, \ldots\}^2$ satisfy (2.9.13). Consider this λ and this T. Since T is column-strict, the entries of T increase weakly left-to-right along rows, and increase strictly top-to-bottom along columns.

For every $u \in \mathbb{N}$ and $j \in \{1, 2, 3, ...\}$, we have

$$\begin{aligned} &(\text{the number of all entries } \leq u \text{ in the } j\text{-th row of } T) \\ &= \sum_{i=1}^{u} \underbrace{(\text{the number of all entries } i \text{ in the } j\text{-th row of } T)}_{\substack{=b_{i,j} \\ (\text{by (2.9.13)})}} = \sum_{i=1}^{u} b_{i,j} \\ &= b_{1,j} + b_{2,j} + \cdots + b_{u,j} . \end{aligned} \tag{13.94.1}$$

Let $(i, j) \in \mathbb{N} \times \{1, 2, 3, \ldots\}$. We are going to prove that

$$\mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) \leq \mu_j + (b_{1,j} + b_{2,j} + \cdots + b_{i,j}) . \tag{13.94.2}$$

Indeed, assume the contrary. Then,

$$\mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) > \mu_j + (b_{1,j} + b_{2,j} + \cdots + b_{i,j}) . \tag{13.94.3}$$

Hence,

$$\begin{aligned} &\mu_{j+1} + \underbrace{(\text{the number of all entries } \leq i+1 \text{ in the } (j+1)\text{-th row of } T)}_{\substack{=b_{1,j+1}+b_{2,j+1}+\cdots+b_{i+1,j+1} \\ (\text{by (13.94.1), applied to } i+1 \text{ and } j+1 \text{ instead of } u \text{ and } j)}} \\ &= \mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) \\ &> \mu_j + \underbrace{(b_{1,j} + b_{2,j} + \cdots + b_{i,j})}_{\geq 0} > \mu_j \geq \mu_{j+1} \qquad (\text{since } \mu \text{ is a partition}) . \end{aligned}$$

Subtracting μ_{j+1} from both sides of this inequality, we obtain

$$(\text{the number of all entries } \leq i+1 \text{ in the } (j+1)\text{-th row of } T) > 0.$$

In other words, there exists at least one entry $\leq i + 1$ in the $(j + 1)$-th row of T. Let $\mathbf{c}$ be the rightmost cell of the $(j + 1)$-th row of T which contains such an entry. That is, $\mathbf{c}$ is the rightmost cell of the $(j + 1)$-th row of T which contains an entry $\leq i + 1$.

The cell $\mathbf{c}$ lies in the $(j + 1)$-th row of T. Hence, we can write the cell $\mathbf{c}$ in the form $\mathbf{c} = (j + 1, y)$ for some positive integer y. Consider this y.

The entries of T increase weakly left-to-right along rows. Thus, the cells of the $(j + 1)$-th row of T which contain entries $\leq i + 1$ form a contiguous segment of the $(j + 1)$-th row of T. This segment begins in cell

$(j+1, \mu_{j+1}+1)$ (since the entries of the $(j+1)$-th row of T begin in cell $(j+1, \mu_{j+1}+1)$ (because T has shape λ/μ)), and ends in cell $(j+1, y)$ (since $(j+1, y) = \mathbf{c}$ is the rightmost cell of the $(j+1)$-th row of T which contains an entry $\leq i+1$). Hence, this segment contains precisely $y - \mu_{j+1}$ cells. In other words, there exist exactly $y - \mu_{j+1}$ cells of the $(j+1)$-th row of T which contain entries $\leq i+1$. In other words, the number of all cells of the $(j+1)$-th row of T which contain entries $\leq i+1$ is $y - \mu_{j+1}$. In other words,

$$(\text{the number of all entries } \leq i+1 \text{ in the } (j+1)\text{-th row of } T) = y - \mu_{j+1}.$$

Solving this for y, we obtain

$$y = \mu_{j+1} + (\text{the number of all entries } \leq i+1 \text{ in the } (j+1)\text{-th row of } T).$$

Since $\mathbf{c}$ is a cell of the tableau T, it is clear that the cell $\mathbf{c}$ lies inside the Ferrers diagram of λ, and therefore (due to $j \in \{1, 2, 3, ...\}$) the cell (j, y) must also lie inside the Ferrers diagram of λ (because the cell (j, y) is the northern neighbor of the cell $(j+1, y) = \mathbf{c}$).

We have

$$\begin{aligned} y &= \mu_{j+1} + (\text{the number of all entries } \leq i+1 \text{ in the } (j+1)\text{-th row of } T) \\ &= \mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) > \mu_j. \end{aligned}$$

Therefore, the cell (j, y) lies outside the Ferrers diagram of μ. Since (j, y) lies inside the Ferrers diagram of λ but outside the Ferrers diagram of μ, we see that (j, y) is a cell of T.

But recall that the entries of T increase strictly top-to-bottom along columns. Hence, the entry of T in the cell (j, y) must be strictly smaller than the entry of T in the cell $\mathbf{c}$ (since the cell (j, y) is the northern neighbor of the cell $(j+1, y) = \mathbf{c}$). Since the latter entry is $\leq i+1$ (by the definition of $\mathbf{c}$), this shows that the entry of T in the cell (j, y) must be strictly smaller than $i+1$. Hence, this entry must be $\leq i$. As a consequence, all cells in the j-th row of T which lie weakly to the left of the cell (j, y) must also have entries $\leq i$ (because the entries of T increase weakly left-to-right along rows). The number of such cells is $y - \mu_j$ (because the entries in the j-th row of T begin in cell $(j, \mu_j + 1)$ (since T has shape λ/μ)). Thus, there are at least $y - \mu_j$ cells in the j-th row of T which have entries $\leq i$; in other words, the number of all entries $\leq i$ in the j-th row of T is at least $y - \mu_j$. In other words,

$$(\text{the number of all entries } \leq i \text{ in the } j\text{-th row of } T) \geq y - \mu_j.$$

Since

$$(\text{the number of all entries } \leq i \text{ in the } j\text{-th row of } T) = b_{1,j} + b_{2,j} + \cdots + b_{i,j}$$

(by (13.94.1), applied to $u = i$), this rewrites as follows:

$$b_{1,j} + b_{2,j} + \cdots + b_{i,j} \geq y - \mu_j.$$

Now, (13.94.3) becomes

$$\begin{aligned} \mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) > \mu_j + \underbrace{(b_{1,j} + b_{2,j} + \cdots + b_{i,j})}_{\geq y - \mu_j} \geq \mu_j + (y - \mu_j) \\ = y = \mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}). \end{aligned}$$

This is absurd. This contradiction proves that our assumption was wrong. Hence, (13.94.2) holds.

Now, forget that we have fixed (i, j). We thus have proven that the inequality (13.94.2) holds for all $(i, j) \in \mathbb{N} \times \{1, 2, 3, \ldots\}$. In other words, Assertion $\mathcal{B}$ holds. We thus have proven the implication $\mathcal{A} \Longrightarrow \mathcal{B}$.

Proof of the implication $\mathcal{B} \Longrightarrow \mathcal{A}$: Assume that Assertion $\mathcal{B}$ holds. That is, the inequality (2.9.14) holds for all $(i, j) \in \mathbb{N} \times \{1, 2, 3, \ldots\}$.

For every $j \in \{1, 2, 3, ...\}$, the sum $b_{1,j} + b_{2,j} + b_{3,j} + \cdots$ has only finitely many nonzero addends (since $b_{i,j} = 0$ for all but finitely many pairs (i, j)), and can be computed as the following limit with respect to the discrete topology:

$$b_{1,j} + b_{2,j} + b_{3,j} + \cdots = \lim_{i \to \infty} (b_{1,j} + b_{2,j} + \cdots + b_{i,j}). \tag{13.94.4}$$

For every $j \in \{1, 2, 3, ...\}$, we have

$$\mu_j + (b_{1,j} + b_{2,j} + b_{3,j} + \cdots) \geq \mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + b_{3,j+1} + \cdots) \tag{13.94.5}$$

[741]. Hence, we can define a partition λ by

$$(\lambda_j = \mu_j + (b_{1,j} + b_{2,j} + b_{3,j} + \cdots) \qquad \text{for every } j \in \{1,2,3,...\}) \tag{13.94.6}$$

[742]. Consider this partition λ.

We have $\mu \subseteq \lambda$ (since every $j \in \{1,2,3,...\}$ satisfies $\lambda_j = \mu_j + \underbrace{(b_{1,j} + b_{2,j} + b_{3,j} + \cdots)}_{\geq 0} \geq \mu_j$). We also have

$$\lambda_j - \mu_j = b_{1,j} + b_{2,j} + b_{3,j} + \cdots \qquad \text{for every } j \in \{1,2,3,...\}$$

(because of (13.94.6)).

Now, we construct a filling T of the Ferrers diagram of λ/μ with positive integers as follows: For every $j \in \{1,2,3,...\}$, the j-th row of this Ferrers diagram of λ/μ has $\lambda_j - \mu_j = b_{1,j} + b_{2,j} + b_{3,j} + \cdots$ cells. We fill in the leftmost $b_{1,j}$ of these cells with 1's, the leftmost $b_{2,j}$ of the remaining cells with 2's, the leftmost $b_{3,j}$ of the still remaining cells with 3's, and so on. Once this has been done for all positive integers j (of course, for all sufficiently high j, the j-th row of the Ferrers diagram of λ/μ has no cells, and therefore nothing has to be filled), we are left with a filling of the Ferrers diagram of λ/μ with positive integers. Denote this filling by T. It is clear that the entries of T increase weakly left-to-right in rows (by the construction of T). We shall soon show that the entries of T increase strictly top-to-bottom in columns.

First, however, let us observe that (2.9.13) holds for all $(i,j) \in \{1,2,3,\ldots\}^2$ (by the construction of T). Hence, every $u \in \mathbb{N}$ and $j \in \{1,2,3,...\}$ satisfy (13.94.1) (this is proven just as in our proof of the implication $\mathcal{A} \Longrightarrow \mathcal{B}$).

Now, we are going to prove that the entries of T increase strictly top-to-bottom in columns.

Indeed, assume the contrary. Then, there exists at least one column of T in which the entries don't increase strictly top-to-bottom. Let this be the k-th column. So the entries in the k-th column of T don't increase strictly top-to-bottom. As a consequence, there exist two cells $\mathbf{c}$ and $\mathbf{d}$ in the k-th column of T such that $\mathbf{d}$ is the northern neighbor of $\mathbf{c}$, but the entry of T in cell $\mathbf{d}$ is not smaller than the entry of T in cell $\mathbf{c}$. Consider these cells $\mathbf{c}$ and $\mathbf{d}$.

Write the cell $\mathbf{c}$ as $\mathbf{c} = (x,y)$. Then, $\mathbf{d} = (x-1,y)$ (since $\mathbf{d}$ is the northern neighbor of $\mathbf{c}$), so that $x - 1 \geq 1$.

Let p be the entry of T in cell $\mathbf{c}$. Then, the entry of T in cell $\mathbf{d}$ is not smaller than p (since the entry of T in cell $\mathbf{d}$ is not smaller than the entry of T in cell $\mathbf{c}$). In other words, the entry of T in cell $(x-1,y)$ is not

[741] *Proof.* Let $j \in \{1,2,3,...\}$. Then,

$$\begin{aligned}
&\mu_{j+1} + \underbrace{(b_{1,j+1} + b_{2,j+1} + b_{3,j+1} + \cdots)}_{\substack{=\lim_{i\to\infty}(b_{1,j+1}+b_{2,j+1}+\cdots+b_{i,j+1}) \\ \text{(by (13.94.4), applied to } j+1 \text{ instead of } j)}} \\
&= \mu_{j+1} + \underbrace{\lim_{i\to\infty}(b_{1,j+1} + b_{2,j+1} + \cdots + b_{i,j+1})}_{\substack{=\lim_{i\to\infty}(b_{1,j+1}+b_{2,j+1}+\cdots+b_{i+1,j+1}) \\ \text{(here, we substituted } i+1 \text{ for } i \text{ in the limit)}}} \\
&= \mu_{j+1} + \lim_{i\to\infty}(b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) = \lim_{i\to\infty}\left(\underbrace{\mu_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1})}_{\substack{\leq \mu_j + (b_{1,j}+b_{2,j}+\cdots+b_{i,j}) \\ \text{(by (2.9.14))}}}\right) \\
&\leq \lim_{i\to\infty}(\mu_j + (b_{1,j} + b_{2,j} + \cdots + b_{i,j})) = \mu_j + \underbrace{\lim_{i\to\infty}(b_{1,j} + b_{2,j} + \cdots + b_{i,j})}_{\substack{=b_{1,j}+b_{2,j}+b_{3,j}+\cdots \\ \text{(by (13.94.4))}}} = \mu_j + (b_{1,j} + b_{2,j} + b_{3,j} + \cdots),
\end{aligned}$$

and this proves (13.94.5).

[742] Here, we are using the fact that $\mu_j + (b_{1,j} + b_{2,j} + b_{3,j} + \cdots) = 0$ for all sufficiently high positive integers j. The proof of this is easy: We have $\mu_j = 0$ for all sufficiently high positive integers j (since μ is a partition), and we also have $b_{1,j} + b_{2,j} + b_{3,j} + \cdots = 0$ for all sufficiently high positive integers j (since $b_{i,j} = 0$ for all but finitely many pairs (i,j)). Thus, if a positive integer j is sufficiently high, we have both $\mu_j = 0$ and $b_{1,j} + b_{2,j} + b_{3,j} + \cdots = 0$, and therefore $\mu_j + (b_{1,j} + b_{2,j} + b_{3,j} + \cdots) = 0 + 0 = 0$, qed.

smaller than p (since $\mathbf{d} = (x-1, y)$). In other words,

$$\text{(the entry of } T \text{ in cell } (x-1,y)) \geq p. \tag{13.94.7}$$

But let $i = p-1$. Then, $i+1 = p$ is the entry of T in cell $\mathbf{c} = (x,y)$. Thus, the cell (x,y) of T has the entry $i+1$. Hence, all cells in the x-th row of T which lie weakly to the left of the cell (x,y) must have entries $\leq i+1$ (since the entries of T increase weakly left-to-right in rows). The number of such cells is $y - \mu_x$ (since the entries in the x-th row of T begin in cell $(x, \mu_x + 1)$ (since T has shape λ/μ)). Thus, there are at least $y - \mu_x$ cells in the x-th row of T which have entries $\leq i+1$; in other words, the number of all entries $\leq i+1$ in the x-th row of T is at least $y - \mu_x$. In other words,

$$\text{(the number of all entries } \leq i+1 \text{ in the } x\text{-th row of } T) \geq y - \mu_x .$$

Since (the number of all entries $\leq i+1$ in the x-th row of T) $= b_{1,x} + b_{2,x} + \cdots + b_{i+1,x}$ (by (13.94.1), applied to $u = i+1$ and $j = x$), this rewrites as follows:

$$b_{1,x} + b_{2,x} + \cdots + b_{i+1,x} \geq y - \mu_x .$$

Now, recall that $x - 1 \geq 1$, so that $x - 1 \in \{1, 2, 3, ...\}$. Hence, (2.9.14) (applied to $j = x-1$) yields

$$\mu_{(x-1)+1} + \left(b_{1,(x-1)+1} + b_{2,(x-1)+1} + \cdots + b_{i+1,(x-1)+1}\right) \leq \mu_{x-1} + \left(b_{1,x-1} + b_{2,x-1} + \cdots + b_{i,x-1}\right),$$

so that

$$\begin{aligned} \mu_{x-1} + \left(b_{1,x-1} + b_{2,x-1} + \cdots + b_{i,x-1}\right) &\geq \underbrace{\mu_{(x-1)+1}}_{=\mu_x} + \underbrace{\left(b_{1,(x-1)+1} + b_{2,(x-1)+1} + \cdots + b_{i+1,(x-1)+1}\right)}_{=b_{1,x}+b_{2,x}+\cdots+b_{i+1,x} \geq y-\mu_x} \\ &\geq \mu_x + y - \mu_x = y. \end{aligned} \tag{13.94.8}$$

But every entry $\leq i$ in the $(x-1)$-st row of T must lie in a cell strictly left of the cell $(x-1, y)$ [743]. Since the number of such cells[744] is $y - 1 - \mu_{x-1}$ (because the entries in the $(x-1)$-st row of T begin in cell $(x-1, \mu_{x-1}+1)$ (since T has shape λ/μ)), this yields that there are at most $y - 1 - \mu_{x-1}$ entries $\leq i$ in the $(x-1)$-st row of T. In other words, the number of all entries $\leq i$ in the $(x-1)$-st row of T is at most $y - 1 - \mu_{x-1}$. In other words,

$$\text{(the number of all entries } \leq i \text{ in the } (x-1)\text{-st row of } T) \leq y - 1 - \mu_{x-1}.$$

Since (the number of all entries $\leq i$ in the $(x-1)$-st row of T) $= b_{1,x-1} + b_{2,x-1} + \cdots + b_{i,x-1}$ (by (13.94.1), applied to $u = i$ and $j = x-1$), this rewrites as follows:

$$b_{1,x-1} + b_{2,x-1} + \cdots + b_{i,x-1} \leq y - \underbrace{1}_{>0} - \mu_{x-1} < y - \mu_{x-1}.$$

Hence, $\mu_{x-1} + \left(b_{1,x-1} + b_{2,x-1} + \cdots + b_{i,x-1}\right) < y$. This contradicts (13.94.8). This contradiction shows that our assumption was wrong. Hence, the entries of T increase strictly top-to-bottom in columns. Since we also know that the entries of T increase weakly left-to-right in rows, and that T is a filling of the Ferrers diagram of λ/μ, this yields that T is a column-strict tableau of shape λ/μ. Besides, we already know that all $(i,j) \in \{1, 2, 3, \ldots\}^2$ satisfy (2.9.13). Hence, Assertion $\mathcal{A}$ holds (with the λ and T that we have constructed above). We thus have proven the implication $\mathcal{B} \Longrightarrow \mathcal{A}$.

Now that both implications $\mathcal{A} \Longrightarrow \mathcal{B}$ and $\mathcal{B} \Longrightarrow \mathcal{A}$ are proven, we conclude that Assertions $\mathcal{A}$ and $\mathcal{B}$ are equivalent. Exercise 2.9.18(a) is solved.

[743] *Proof.* Assume the contrary. Then, there exists an entry $\leq i$ in the $(x-1)$-st row of T which lies in a cell not strictly left of the cell $(x-1, y)$. Let c be this entry. Since c lies in a cell not strictly left of the cell $(x-1,y)$, the entry c must lie in a cell weakly to the right of the cell $(x-1, y)$, and therefore this entry c must be $\geq$ to the entry of T in cell $(x-1, y)$ (because the entries of T increase weakly left-to-right in rows). Hence,

$$\begin{aligned} c &\geq \text{(the entry of } T \text{ in cell } (x-1,y)) \geq p \qquad \text{(by (13.94.7))} \\ &> i \qquad \text{(since } i = p-1 < p\text{)}, \end{aligned}$$

which contradicts the fact that $c \leq i$ (by definition of c). This contradiction shows that our assumption was wrong, qed.

[744] Here, "such cells" means cells of the $(x-1)$-st row of T which lie strictly left of the cell $(x-1, y)$.

(b) Since T is a column-strict tableau, we know that the entries of T increase weakly left-to-right in rows and increase strictly top-to-bottom along columns. Hence, if $\mathbf{c}$ and $\mathbf{d}$ are two cells of T such that the cell $\mathbf{c}$ lies southeast[745] of the cell $\mathbf{d}$, then

$$(\text{the entry of } T \text{ in cell } \mathbf{c}) \geq (\text{the entry of } T \text{ in cell } \mathbf{d}) . \tag{13.94.9}$$

For the same reason, if $\mathbf{c}$ and $\mathbf{d}$ are two cells of T such that the cell $\mathbf{c}$ lies southeast of the cell $\mathbf{d}$ but not on the same row as $\mathbf{d}$, then

$$(\text{the entry of } T \text{ in cell } \mathbf{c}) > (\text{the entry of } T \text{ in cell } \mathbf{d}) . \tag{13.94.10}$$

We shall first prove the equivalence of Assertions $\mathcal{D}$ and $\mathcal{G}$:

Proof of the equivalence $\mathcal{D} \Longleftrightarrow \mathcal{G}$: For every $(i,j) \in \{1,2,3,...\}^2$, let $b_{i,j}$ be the number of all entries j in the i-th row of T. (This is not a typo; we don't want the number of all entries i in the j-th row of T.)

It is clear that $b_{i,j} = 0$ for all but finitely many pairs (i,j). Hence, we can apply Exercise 2.9.18(a) to $\varnothing$ instead of μ. We conclude that the following two assertions $\mathcal{A}'$ and $\mathcal{B}'$ are equivalent[746]:

- *Assertion $\mathcal{A}'$:* There exist a partition ν and a column-strict tableau S of shape $\nu/\varnothing$ such that all $(i,j) \in \{1,2,3,\ldots\}^2$ satisfy
$$b_{i,j} = (\text{the number of all entries } i \text{ in the } j\text{-th row of } S) .$$
- *Assertion $\mathcal{B}'$:* The inequality
$$\varnothing_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) \leq \varnothing_j + (b_{1,j} + b_{2,j} + \cdots + b_{i,j})$$
holds for all $(i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}$.

Now, it is easy to see that Assertion $\mathcal{A}'$ is equivalent to Assertion $\mathcal{G}$ [747]. Also, Assertion $\mathcal{B}'$ is equivalent to Assertion $\mathcal{D}$ [748]. Altogether, we have obtained the chain of equivalences $\mathcal{D} \Longleftrightarrow \mathcal{B}' \Longleftrightarrow \mathcal{A}' \Longleftrightarrow \mathcal{G}$.

[745] A cell (r,c) is said to lie *southeast* of a cell (r',c') if and only if we have $r \geq r'$ and $c \geq c'$.

[746] Note that we denote by ν and S the variables that have been called λ and T in Exercise 2.9.18(a), since in our current situation the letters λ and T already have different meanings.

[747] *Proof.* Assertion $\mathcal{A}'$ is equivalent to the following Assertion $\mathcal{A}''$:

- *Assertion $\mathcal{A}''$:* There exists a column-strict tableau S whose shape is a partition such that all $(i,j) \in \{1,2,3,\ldots\}^2$ satisfy
$$b_{i,j} = (\text{the number of all entries } i \text{ in the } j\text{-th row of } S) .$$

(Indeed, Assertion $\mathcal{A}'$ is equivalent to Assertion $\mathcal{A}''$ because a column-strict tableau whose shape is a partition is the same thing as a column-strict tableau of shape $\nu/\varnothing$ with ν being a partition.)

Recall that $b_{i,j} = (\text{the number of all entries } j \text{ in the } i\text{-th row of } T)$ for all $(i,j) \in \{1,2,3,...\}^2$ (by the definition of $b_{i,j}$). Hence, Assertion $\mathcal{A}''$ is equivalent to the following Assertion $\mathcal{A}'''$:

- *Assertion $\mathcal{A}'''$:* There exists a column-strict tableau S whose shape is a partition such that all $(i,j) \in \{1,2,3,\ldots\}^2$ satisfy
$$(\text{the number of all entries } j \text{ in the } i\text{-th row of } T) = (\text{the number of all entries } i \text{ in the } j\text{-th row of } S) .$$

Assertion $\mathcal{A}'''$ is equivalent to the following Assertion $\mathcal{A}''''$:

- *Assertion $\mathcal{A}''''$:* There exists a column-strict tableau S whose shape is a partition such that all $(i,j) \in \{1,2,3,\ldots\}^2$ satisfy
$$(\text{the number of all entries } i \text{ in the } j\text{-th row of } T) = (\text{the number of all entries } j \text{ in the } i\text{-th row of } S) .$$

(Indeed, Assertion $\mathcal{A}''''$ is obtained from Assertion $\mathcal{A}'''$ by substituting (j,i) for the index (i,j).)

Assertion $\mathcal{A}''''$ is obviously equivalent to Assertion $\mathcal{G}$.

Altogether, we have obtained the chain of equivalences $\mathcal{A}' \Longleftrightarrow \mathcal{A}'' \Longleftrightarrow \mathcal{A}''' \Longleftrightarrow \mathcal{A}'''' \Longleftrightarrow \mathcal{G}$. Thus, we know that Assertion $\mathcal{A}'$ is equivalent to Assertion $\mathcal{G}$, qed.

[748] *Proof.* Every $(i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}$ satisfies

$$\begin{aligned}
\underbrace{\varnothing_j}_{=0} + (b_{1,j} + b_{2,j} + \cdots + b_{i,j}) &= b_{1,j} + b_{2,j} + \cdots + b_{i,j} = \sum_{u=1}^{i} \underbrace{b_{u,j}}_{\substack{=(\text{the number of all entries } j \text{ in the } u\text{-th row of } T) \\ (\text{by the definition of } b_{u,j})}} \\
&= \sum_{u=1}^{i} (\text{the number of all entries } j \text{ in the } u\text{-th row of } T) \\
&= (\text{the number of all entries } j \text{ in the first } i \text{ rows of } T) \qquad (13.94.11)
\end{aligned}$$

and

$$\varnothing_{j+1} + (b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}) = (\text{the number of all entries } j+1 \text{ in the first } i+1 \text{ rows of } T) \tag{13.94.12}$$

Hence, we have proven the equivalence $\mathcal{D} \Longleftrightarrow \mathcal{G}$. In order to complete the solution of Exercise 2.9.18(b), it thus remains to prove the equivalence $\mathcal{C} \Longleftrightarrow \mathcal{D} \Longleftrightarrow \mathcal{E} \Longleftrightarrow \mathcal{F}$.

We will achieve this by splitting each of the assertions $\mathcal{C}$, $\mathcal{D}$, $\mathcal{E}$ and $\mathcal{F}$ into many sub-assertions. Namely, for every $i \in \{1,2,3,...\}$, let us define four assertions $\mathcal{C}_i$, $\mathcal{D}_i$, $\mathcal{E}_i$ and $\mathcal{F}_i$ as follows:

- *Assertion $\mathcal{C}_i$:* For every positive integer j, we have $\left(\operatorname{cont}\left(T|_{\text{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\text{cols}\geq j}\right)\right)_{i+1}$.
- *Assertion $\mathcal{D}_i$:* For every positive integer j, the number of entries $i+1$ in the first j rows of T is $\leq$ to the number of entries i in the first $j-1$ rows of T.
- *Assertion $\mathcal{E}_i$:* For every NE-set S of T, we have $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$.
- *Assertion $\mathcal{F}_i$:* For every prefix v of the Semitic reading word of T, there are at least as many i's among the letters of v as there are $(i+1)$'s among them.

We have the following equivalences:

$$\mathcal{C} \Longleftrightarrow \left(\mathcal{C}_i \text{ holds for every } i \in \{1,2,3,...\}\right)$$

(since $\operatorname{cont}\left(T|_{\text{cols}\geq j}\right)$ is a partition if and only if every $i \in \{1,2,3,...\}$ satisfies $\left(\operatorname{cont}\left(T|_{\text{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\text{cols}\geq j}\right)\right)_{i+1}$), and

$$\mathcal{D} \Longleftrightarrow \left(\mathcal{D}_i \text{ holds for every } i \in \{1,2,3,...\}\right)$$

(obviously), and

$$\mathcal{E} \Longleftrightarrow \left(\mathcal{E}_i \text{ holds for every } i \in \{1,2,3,...\}\right)$$

(since $\operatorname{cont}\left(T|_S\right)$ is a partition if and only if every $i \in \{1,2,3,...\}$ satisfies $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$), and

$$\mathcal{F} \Longleftrightarrow \left(\mathcal{F}_i \text{ holds for every } i \in \{1,2,3,...\}\right)$$

(by the definition of a Yamanouchi word). Hence, in order to prove the equivalence $\mathcal{C} \Longleftrightarrow \mathcal{D} \Longleftrightarrow \mathcal{E} \Longleftrightarrow \mathcal{F}$, it is enough to show that for every $i \in \{1,2,3,...\}$, we have an equivalence $\mathcal{C}_i \Longleftrightarrow \mathcal{D}_i \Longleftrightarrow \mathcal{E}_i \Longleftrightarrow \mathcal{F}_i$. So let us do this now.

Let $i \in \{1,2,3,...\}$. We need to prove the equivalence $\mathcal{C}_i \Longleftrightarrow \mathcal{D}_i \Longleftrightarrow \mathcal{E}_i \Longleftrightarrow \mathcal{F}_i$. We shall achieve this by proving the implications $\mathcal{C}_i \Longrightarrow \mathcal{E}_i$, $\mathcal{E}_i \Longrightarrow \mathcal{F}_i$, $\mathcal{F}_i \Longrightarrow \mathcal{D}_i$ and $\mathcal{D}_i \Longrightarrow \mathcal{C}_i$.

Proof of the implication $\mathcal{C}_i \Longrightarrow \mathcal{E}_i$: Assume that Assertion $\mathcal{C}_i$ holds. Let S be an NE-set of T. We will prove that $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$.

Assume the contrary. Thus, $\left(\operatorname{cont}\left(T|_S\right)\right)_i < \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$. In other words, $\left(\operatorname{cont}\left(T|_S\right)\right)_{i+1} > \left(\operatorname{cont}\left(T|_S\right)\right)_i$. Recall that

$$\left(\operatorname{cont}\left(T|_S\right)\right)_i = \left|\left(T|_S\right)^{-1}(i)\right| = \left(\text{the number of entries } i \text{ in } T|_S\right)$$

and

$$\left(\operatorname{cont}\left(T|_S\right)\right)_{i+1} = \left|\left(T|_S\right)^{-1}(i+1)\right| = \left(\text{the number of entries } i+1 \text{ in } T|_S\right).$$

Hence,

$$\begin{aligned}\left(\text{the number of entries } i+1 \text{ in } T|_S\right) &= \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1} > \left(\operatorname{cont}\left(T|_S\right)\right)_i \\ &= \left(\text{the number of entries } i \text{ in } T|_S\right) \geq 0.\end{aligned}$$

Hence, there exists at least one entry $i+1$ in $T|_S$. In other words, there exists at least one cell $\mathbf{c} \in S$ such that the entry of T in $\mathbf{c}$ equals $i+1$. Let $\mathbf{d}$ be the **leftmost** such cell $\mathbf{c}$ (or one of the leftmost, if there are

(by (13.94.11), applied to $(i+1, j+1)$ instead of (i,j)). Hence, Assertion $\mathcal{B}'$ is equivalent to the following Assertion $\mathcal{B}''$:

- *Assertion $\mathcal{B}''$:* The inequality

$$(\text{the number of all entries } j+1 \text{ in the first } i+1 \text{ rows of } T) \leq (\text{the number of all entries } j \text{ in the first } i \text{ rows of } T)$$

holds for all $(i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}$.

This Assertion $\mathcal{B}''$, in turn, is equivalent to the following Assertion $\mathcal{B}'''$:

- *Assertion $\mathcal{B}'''$:* The inequality

$$(\text{the number of all entries } i+1 \text{ in the first } j \text{ rows of } T) \leq (\text{the number of all entries } i \text{ in the first } j-1 \text{ rows of } T)$$

holds for all $(i,j) \in \{1,2,3,\ldots\} \times \{1,2,3,\ldots\}$.

(Indeed, Assertion $\mathcal{B}'''$ is obtained from Assertion $\mathcal{B}''$ by substituting $(j-1, i)$ for the index (i,j).) But Assertion $\mathcal{B}'''$ is clearly equivalent to Assertion $\mathcal{D}$.

We thus have found the chain of equivalences $\mathcal{B}' \Longleftrightarrow \mathcal{B}'' \Longleftrightarrow \mathcal{B}''' \Longleftrightarrow \mathcal{D}$. Thus, Assertion $\mathcal{B}'$ is equivalent to Assertion $\mathcal{D}$, qed.

several of them[749]). Thus, we have $\mathbf{d} \in S$, and the entry of T in $\mathbf{d}$ equals $i+1$. Let j be the column in which this cell $\mathbf{d}$ lies. Assertion $\mathcal{C}_i$ then yields $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}$. It is rather clear that $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$ [750].

We shall now show that $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i$. Indeed, let $\mathbf{c}$ be a cell of $T|_{\operatorname{cols}\geq j}$ such that the entry of T in $\mathbf{c}$ equals i. We shall show that $\mathbf{c} \in S$.

Write the cell $\mathbf{d}$ as $\mathbf{d} = (x, j)$ for some positive integer x (this is possible, since $\mathbf{d}$ lies in column j). Write the cell $\mathbf{c}$ as $\mathbf{c} = (x', y')$ for two positive integers x' and y'. Then, y' is the column in which the cell $\mathbf{c}$ lies. Since this column is one of the columns $j, j+1, j+2, \ldots$ (because $\mathbf{c}$ is a cell of $T|_{\operatorname{cols}\geq j}$), this yields that $y' \in \{j, j+1, j+2, \ldots\}$, so that $y' \geq j$.

If $x' \geq x$, then the cell (x', y') lies southeast of the cell (x, j) (since $x' \geq x$ and $y' \geq j$). Since $(x', y') = \mathbf{c}$ and $(x, j) = \mathbf{d}$, this rewrites as follows: If $x' \geq x$, then the cell $\mathbf{c}$ lies southeast of the cell $\mathbf{d}$. Hence, if $x' \geq x$, then (13.94.9) yields

$$(\text{the entry of } T \text{ in cell } \mathbf{c}) \geq (\text{the entry of } T \text{ in cell } \mathbf{d}) = i+1,$$

which contradicts $(\text{the entry of } T \text{ in cell } \mathbf{c}) = i < i+1$. Therefore, we cannot have $x' \geq x$. We thus have $x' < x$.

Since $x' < x$ and $y' \geq j$, the cell (x', y') lies northeast of the cell (x, j). In other words, the cell $\mathbf{c}$ lies northeast of the cell $\mathbf{d}$ (since $(x', y') = \mathbf{c}$ and $(x, j) = \mathbf{d}$). Since $\mathbf{c}$ is a cell of T and since $\mathbf{d} \in S$, this yields that $\mathbf{c} \in S$ as well (since S is an NE-set).

Now, forget that we fixed $\mathbf{c}$. We thus have shown that if $\mathbf{c}$ is a cell of $T|_{\operatorname{cols}\geq j}$ such that the entry of T in $\mathbf{c}$ equals i, then $\mathbf{c} \in S$. Hence, the set

$$\left\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\right\}$$

is a subset of the set

$$\{\mathbf{c} \in S \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\}.$$

As a consequence,

$$\begin{aligned}
&\left|\left\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\right\}\right| \\
&\leq |\{\mathbf{c} \in S \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\}| \\
&= (\text{the number of entries } i \text{ in } T|_S) = \left(\operatorname{cont}\left(T|_S\right)\right)_i .
\end{aligned}$$

Since

$$\begin{aligned}
&\left|\left\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\right\}\right| \\
&= \left(\text{the number of entries } i \text{ in } T|_{\operatorname{cols}\geq j}\right) = \left|\left(T|_{\operatorname{cols}\geq j}\right)^{-1}(i)\right| = \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i
\end{aligned}$$

[749] A moment's thought reveals that there cannot be several of them, but we don't actually need to think about this.

[750] *Proof.* We have defined $\mathbf{d}$ as the leftmost cell $\mathbf{c} \in S$ such that the entry of T in $\mathbf{c}$ equals $i+1$. Hence, if $\mathbf{c} \in S$ is any cell such that the entry of T in $\mathbf{c}$ equals $i+1$, then $\mathbf{c}$ lies in the same column as $\mathbf{d}$ or in some column further right. Since $\mathbf{d}$ lies in column j, this rewrites as follows: If $\mathbf{c} \in S$ is any cell such that the entry of T in $\mathbf{c}$ equals $i+1$, then $\mathbf{c}$ lies in column j or in some column further right. In other words, if $\mathbf{c} \in S$ is any cell such that the entry of T in $\mathbf{c}$ equals $i+1$, then $\mathbf{c}$ lies in one of the columns $j, j+1, j+2, \ldots$. In other words, if $\mathbf{c} \in S$ is any cell such that the entry of T in $\mathbf{c}$ equals $i+1$, then $\mathbf{c}$ is a cell of $T|_{\operatorname{cols}\geq j}$. Thus, the set

$$\{\mathbf{c} \in S \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\}$$

is a subset of the set

$$\left\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\right\}.$$

As a consequence,

$$\begin{aligned}
&|\{\mathbf{c} \in S \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\}| \\
&\leq \left|\left\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\right\}\right| \\
&= \left(\text{the number of entries } i+1 \text{ in } T|_{\operatorname{cols}\geq j}\right) = \left|\left(T|_{\operatorname{cols}\geq j}\right)^{-1}(i+1)\right| = \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}
\end{aligned}$$

(because $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} = \left|\left(T|_{\operatorname{cols}\geq j}\right)^{-1}(i+1)\right|$ (by the definition of $\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)$)). Since

$$\begin{aligned}
&|\{\mathbf{c} \in S \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\}| \\
&= (\text{the number of entries } i+1 \text{ in } T|_S) = \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1},
\end{aligned}$$

this rewrites as $\left(\operatorname{cont}\left(T|_S\right)\right)_{i+1} \leq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}$. Hence, $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$, qed.

(because the definition of $\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)$ shows that $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i = \left|\left(T|_{\operatorname{cols}\geq j}\right)^{-1}(i)\right|$), this rewrites as $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \leq \left(\operatorname{cont}\left(T|_S\right)\right)_i$. In other words, $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i$. Altogether,

$$\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1},$$

which contradicts $\left(\operatorname{cont}\left(T|_S\right)\right)_i < \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$. This contradiction shows that our assumption was wrong. Hence, $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$.

Now, forget that we fixed S. We thus have proven that for every NE-set S of T, we have $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$. Thus, Assertion $\mathcal{E}_i$ holds. This proves the implication $\mathcal{C}_i \Longrightarrow \mathcal{E}_i$.

Proof of the implication $\mathcal{E}_i \Longrightarrow \mathcal{F}_i$: Assume that Assertion $\mathcal{E}_i$ holds. Let v be a prefix of the Semitic reading word of T. We shall prove that there are at least as many i's among the letters of v as there are $(i+1)$'s among them.

For every $i \in \{1,2,3,...\}$, let r_i be the word obtained by reading the i-th row of T from right to left. Then, the Semitic reading word of T is the concatenation $r_1 r_2 r_3 \cdots$ (according to its definition). Hence, every prefix of this Semitic reading word must have the form $r_1 r_2 \cdots r_k s$ for some $k \in \{0,1,2,...\}$ and some prefix s of r_{k+1}. In particular, v must have this form (since v is a prefix of the Semitic reading word of T). In other words, there exists some $k \in \{0,1,2,...\}$ and some prefix s of r_{k+1} such that $v = r_1 r_2 \cdots r_k s$. Consider this k and this s.

Let ℓ be the length of s. Since s is a prefix of r_{k+1} and has length ℓ, it is evident that the word s consists of the first ℓ letters of r_{k+1}. These first ℓ letters of r_{k+1} are the rightmost ℓ entries of the $(k+1)$-st row of T (since r_{k+1} is the word obtained by reading the $(k+1)$-st row of T from right to left). Thus, the word s consists of the rightmost ℓ entries of the $(k+1)$-st row of T. Hence, the word $r_1 r_2 \cdots r_k s$ consists of all entries of the first k rows of T and the rightmost ℓ entries of the $(k+1)$-st row of T. In other words, the letters of the word $r_1 r_2 \cdots r_k s$ are precisely all entries of the first k rows of T and the rightmost ℓ entries of the $(k+1)$-st row of T.

Let S be the set which consists of all cells of the first k rows of T and the rightmost ℓ cells of the $(k+1)$-st row of T. Then, S is an NE-set of T, and therefore we have $\left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1}$ (by Assertion $\mathcal{E}_i$).

Now, $\left(\operatorname{cont}\left(T|_S\right)\right)_i = \left|\left(T|_S\right)^{-1}(i)\right|$ (by the definition of $\operatorname{cont}\left(T|_S\right)$), so that $\left(\operatorname{cont}\left(T|_S\right)\right)_i$ is the number of entries i in $T|_S$. In other words, $\left(\operatorname{cont}\left(T|_S\right)\right)_i$ is the number of i's among the entries of $T|_S$. But since the entries of $T|_S$ are precisely the letters of v [751], this rewrites as follows: $\left(\operatorname{cont}\left(T|_S\right)\right)_i$ is the number of i's among the letters of v. So we have

$$\left(\operatorname{cont}\left(T|_S\right)\right)_i = (\text{the number of } i\text{'s among the letters of } v).$$

The same argument, with $i+1$ in place of i, shows that

$$\left(\operatorname{cont}\left(T|_S\right)\right)_{i+1} = (\text{the number of } (i+1)\text{'s among the letters of } v).$$

Hence,

$$\begin{aligned}(\text{the number of } i\text{'s among the letters of } v) &= \left(\operatorname{cont}\left(T|_S\right)\right)_i \geq \left(\operatorname{cont}\left(T|_S\right)\right)_{i+1} \\ &= (\text{the number of } (i+1)\text{'s among the letters of } v).\end{aligned}$$

In other words, there are at least as many i's among the letters of v as there are $(i+1)$'s among them.

Now, forget that we fixed v. We thus have shown that for every prefix v of the Semitic reading word of T, there are at least as many i's among the letters of v as there are $(i+1)$'s among them. In other words, Assertion $\mathcal{F}_i$ holds. We thus have shown the implication $\mathcal{E}_i \Longrightarrow \mathcal{F}_i$.

Proof of the implication $\mathcal{F}_i \Longrightarrow \mathcal{D}_i$: Assume that Assertion $\mathcal{F}_i$ holds.

For every $i \in \{1,2,3,...\}$, let r_i be the word obtained by reading the i-th row of T from right to left. Then, the Semitic reading word of T is the concatenation $r_1 r_2 r_3 \cdots$ (according to its definition).

Now, let j be a positive integer. The word r_j is the word obtained by reading the j-th row of T from right to left. Hence, the letters of this word r_j are in (weakly) decreasing order (since the entries of T increase

[751] *Proof.* The set S consists of all cells of the first k rows of T and the rightmost ℓ cells of the $(k+1)$-st row of T. Hence, the entries of $T|_S$ are precisely all entries of the first k rows of T and the rightmost ℓ entries of the $(k+1)$-st row of T. Comparing this with the fact that the letters of the word $r_1 r_2 \cdots r_k s$ are precisely all entries of the first k rows of T and the rightmost ℓ entries of the $(k+1)$-st row of T, we conclude the following: The entries of $T|_S$ are precisely the letters of $r_1 r_2 \cdots r_k s$. In other words, the entries of $T|_S$ are precisely the letters of v (since $v = r_1 r_2 \cdots r_k s$), qed.

weakly left-to-right in rows). Thus, the subword of r_j consisting of all letters $> i$ in r_j is a prefix of r_j. Denote this prefix by s. By the definition of s, all letters of s are $> i$, so that

$$(\text{the number of } i\text{'s among the letters of } s) = 0.$$

Also, by the definition of s, the word s consists of all letters $> i$ in r_j. As a consequence,

$$(\text{the number of } (i+1)\text{'s among the letters of } s) = (\text{the number of } (i+1)\text{'s among the letters of } r_j).$$

Since s is a prefix of r_j, it is clear that the word $r_1 r_2 \cdots r_{j-1} s$ is a prefix of the word $r_1 r_2 r_3 \cdots$. In other words, the word $r_1 r_2 \cdots r_{j-1} s$ is a prefix of the Semitic reading word of T (since the Semitic reading word of T is the concatenation $r_1 r_2 r_3 \cdots$). Hence, there are at least as many i's among the letters of $r_1 r_2 \cdots r_{j-1} s$ as there are $(i+1)$'s among them (by Assertion $\mathcal{F}_i$, applied to $v = r_1 r_2 \cdots r_{j-1} s$). In other words,

$$\begin{aligned}&(\text{the number of } i\text{'s among the letters of } r_1 r_2 \cdots r_{j-1} s)\\ &\geq (\text{the number of } (i+1)\text{'s among the letters of } r_1 r_2 \cdots r_{j-1} s).\end{aligned}$$

Since

$$\begin{aligned}&(\text{the number of } i\text{'s among the letters of } r_1 r_2 \cdots r_{j-1} s)\\ &= \sum_{k=1}^{j-1} (\text{the number of } i\text{'s among the letters of } r_k) + \underbrace{(\text{the number of } i\text{'s among the letters of } s)}_{=0}\\ &= \sum_{k=1}^{j-1} \underbrace{(\text{the number of } i\text{'s among the letters of } r_k)}_{\substack{=(\text{the number of entries } i \text{ in the } k\text{-th row of } T)\\ (\text{since } r_k \text{ is the word obtained by reading the } k\text{-th row of } T \text{ from right to left})}}\\ &= \sum_{k=1}^{j-1} (\text{the number of entries } i \text{ in the } k\text{-th row of } T)\\ &= (\text{the number of entries } i \text{ in the first } j-1 \text{ rows of } T)\end{aligned}$$

and

$$\begin{aligned}&(\text{the number of } (i+1)\text{'s among the letters of } r_1 r_2 \cdots r_{j-1} s)\\ &= \sum_{k=1}^{j-1} (\text{the number of } (i+1)\text{'s among the letters of } r_k) + \underbrace{(\text{the number of } (i+1)\text{'s among the letters of } s)}_{=(\text{the number of } (i+1)\text{'s among the letters of } r_j)}\\ &= \sum_{k=1}^{j-1} (\text{the number of } (i+1)\text{'s among the letters of } r_k) + (\text{the number of } (i+1)\text{'s among the letters of } r_j)\\ &= \sum_{k=1}^{j} \underbrace{(\text{the number of } (i+1)\text{'s among the letters of } r_k)}_{\substack{=(\text{the number of entries } i+1 \text{ in the } k\text{-th row of } T)\\ (\text{since } r_k \text{ is the word obtained by reading the } k\text{-th row of } T \text{ from right to left})}}\\ &= \sum_{k=1}^{j} (\text{the number of entries } i+1 \text{ in the } k\text{-th row of } T)\\ &= (\text{the number of entries } i+1 \text{ in the first } j \text{ rows of } T),\end{aligned}$$

this rewrites as follows:

$$\begin{aligned}&(\text{the number of entries } i \text{ in the first } j-1 \text{ rows of } T)\\ &\geq (\text{the number of entries } i+1 \text{ in the first } j \text{ rows of } T).\end{aligned}$$

In other words, the number of entries $i+1$ in the first j rows of T is $\leq$ to the number of entries i in the first $j-1$ rows of T.

Now, forget that we fixed j. We thus have shown that for every positive integer j, the number of entries $i+1$ in the first j rows of T is $\leq$ to the number of entries i in the first $j-1$ rows of T. In other words, Assertion $\mathcal{D}_i$ holds. Thus, we have shown the implication $\mathcal{F}_i \Longrightarrow \mathcal{D}_i$.

Proof of the implication $\mathcal{D}_i \Longrightarrow \mathcal{C}_i$: Assume that Assertion $\mathcal{D}_i$ holds. We want to prove that Assertion $\mathcal{C}_i$ holds. In other words, we want to prove that, for every positive integer j, we have $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}$.

In order to prove this, we assume the contrary. That is, there exists a positive integer j such that we don't have $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}$. Consider the **minimal** such j. Then, we don't have $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}$; but

$$\text{for every } k \in \{1,2,...,j-1\}\text{, we do have } \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq k}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq k}\right)\right)_{i+1}. \tag{13.94.13}$$

Applying (13.94.13) to $k = j-1$, we obtain:

$$\text{if } j-1 \text{ is positive, then we do have } \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j-1}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j-1}\right)\right)_{i+1}. \tag{13.94.14}$$

We don't have $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}$. Thus,

$$\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i < \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}. \tag{13.94.15}$$

In other words, $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} > \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i$. Recall that

$$\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i = \left(\text{the number of entries } i \text{ in } T|_{\operatorname{cols}\geq j}\right) \tag{13.94.16}$$

and

$$\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} = \left(\text{the number of entries } i+1 \text{ in } T|_{\operatorname{cols}\geq j}\right).$$

Hence,

$$\begin{aligned}\left(\text{the number of entries } i+1 \text{ in } T|_{\operatorname{cols}\geq j}\right) &= \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} > \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \\ &= \left(\text{the number of entries } i \text{ in } T|_{\operatorname{cols}\geq j}\right) \geq 0.\end{aligned}$$

Hence, there exists at least one entry $i+1$ in $T|_{\operatorname{cols}\geq j}$. In other words, there exists at least one cell $\mathbf{c}$ of $T|_{\operatorname{cols}\geq j}$ such that the entry of $T|_{\operatorname{cols}\geq j}$ in $\mathbf{c}$ equals $i+1$. In other words, there exists at least one cell $\mathbf{c}$ of $T|_{\operatorname{cols}\geq j}$ such that the entry of T in $\mathbf{c}$ equals $i+1$ (since the entry of $T|_{\operatorname{cols}\geq j}$ in $\mathbf{c}$, when it is defined, equals the entry of T in $\mathbf{c}$). Let r be the **bottommost** row which contains such a cell $\mathbf{c}$, and let (x,y) be the **leftmost** such cell $\mathbf{c}$ on this row. Thus, (x,y) is a cell of $T|_{\operatorname{cols}\geq j}$ such that the entry of T in (x,y) equals $i+1$. Also, the cell (x,y) lies in the r-th row; that is, $r = x$.

The cell (x,y) must lie in one of the columns $j, j+1, j+2, ...$ (since it is a cell of $T|_{\operatorname{cols}\geq j}$), so that we have $y \geq j$. Also, (x,y) is a cell of T (since it is a cell of $T|_{\operatorname{cols}\geq j}$).

Applying Assertion $\mathcal{D}_i$ to x instead of j, we see that the number of entries $i+1$ in the first x rows of T is $\leq$ to the number of entries i in the first $x-1$ rows of T. In other words,

$$\begin{aligned}&\left(\text{the number of entries } i+1 \text{ in the first } x \text{ rows of } T\right) \\ &\leq \left(\text{the number of entries } i \text{ in the first } x-1 \text{ rows of } T\right).\end{aligned} \tag{13.94.17}$$

It is easy to see that

$$\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} \leq \left(\text{the number of entries } i+1 \text{ in the first } x \text{ rows of } T\right) \tag{13.94.18}$$

[752].

We shall now show that

$$\left(\text{the number of entries } i \text{ in the first } x-1 \text{ rows of } T\right) \leq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i. \tag{13.94.19}$$

[752] *Proof.* Let $\mathbf{c}$ be a cell of $T|_{\operatorname{cols}\geq j}$ such that the entry of T in $\mathbf{c}$ equals $i+1$. Since r is the bottommost row which contains such a cell $\mathbf{c}$, it is clear that the cell $\mathbf{c}$ must be in the r-th row or in a row further north. In other words, the cell $\mathbf{c}$ must lie in one of the first r rows of T. Since $r = x$, this rewrites as follows: The cell $\mathbf{c}$ must lie in one of the first x rows of T.

Now, let us forget that we fixed $\mathbf{c}$. We thus have proven that if $\mathbf{c}$ is a cell of $T|_{\operatorname{cols}\geq j}$ such that the entry of T in $\mathbf{c}$ equals $i+1$, then the cell $\mathbf{c}$ must lie in one of the first x rows of T. Hence, the set

$$\left\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\right\}$$

is a subset of the set

$$\{\mathbf{c} \text{ is a cell of } T \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1;\ \text{the cell } \mathbf{c} \text{ lies in one of the first } x \text{ rows of } T\}.$$

Indeed, let $\mathbf{c}$ be a cell of T such that the entry of T in $\mathbf{c}$ equals i and such that $\mathbf{c}$ lies in one of the first $x-1$ rows of T. We shall show that $\mathbf{c}$ is a cell of $T|_{\text{cols}\geq j}$.

Assume the contrary. Thus, $\mathbf{c}$ is not a cell of $T|_{\text{cols}\geq j}$.

Let us write the cell $\mathbf{c}$ as $\mathbf{c} = (x', y')$ for some integers x' and y'. Then, the cell $\mathbf{c}$ lies in row x', and thus this row x' must be one of the first $x-1$ rows of T (since we know that $\mathbf{c}$ lies in one of the first $x-1$ rows of T). In other words, $x' \leq x-1$. Hence, $x' \leq x-1 < x$ and thus $x > x'$ and $x \neq x'$ and $x \geq x'$.

The cell $\mathbf{c}$ lies in the y'-th column (since $\mathbf{c} = (x', y')$). Hence, if $y' \geq j$, then the cell $\mathbf{c}$ lies in one of the columns $j, j+1, j+2, \ldots$ and therefore is a cell of $T|_{\text{cols}\geq j}$, which contradicts our assumption that $\mathbf{c}$ is not a cell of $T|_{\text{cols}\geq j}$. Thus, we cannot have $y' \geq j$. We therefore have $y' < j$. That is, $y' \leq j-1$ (since y' and j are integers), so that $j-1 \geq y'$.

Now, the cell (x, y) lies southeast of the cell $(x, j-1)$ (since $x \geq x$ and $y \geq j \geq j-1$), which in turn lies southeast of the cell (x', y') (since $x \geq x'$ and $j-1 \geq y'$). Since both cells (x, y) and (x', y') are cells of T (indeed, (x, y) is known to be a cell of T, and $(x', y') = \mathbf{c}$ also is a cell of T), this yields that the intermediate cell $(x, j-1)$ is also a cell of T [753]. Thus, $j-1$ is a positive integer. Moreover, since the cell (x, y) lies southeast of the cell $(x, j-1)$, we can apply (13.94.9) to (x, y) and $(x, j-1)$ instead of $\mathbf{c}$ and $\mathbf{d}$. We thus obtain

$$(\text{the entry of } T \text{ in cell } (x, y)) \geq (\text{the entry of } T \text{ in cell } (x, j-1)).$$

Since $(\text{the entry of } T \text{ in cell } (x, y)) = i+1$, this rewrites as

$$i+1 \geq (\text{the entry of } T \text{ in cell } (x, j-1)). \tag{13.94.20}$$

But the cell $(x, j-1)$ lies southeast of the cell (x', y') and not on the same row as (x', y') (since $x \neq x'$). Since $(x', y') = \mathbf{c}$, this rewrites as follows: The cell $(x, j-1)$ lies southeast of the cell $\mathbf{c}$ and not on the same row as $\mathbf{c}$. Hence, (13.94.10) (applied to $(x, j-1)$ and $\mathbf{c}$ instead of $\mathbf{c}$ and $\mathbf{d}$) yields

$$(\text{the entry of } T \text{ in cell } (x, j-1)) > (\text{the entry of } T \text{ in cell } \mathbf{c}) = i,$$

so that

$$(\text{the entry of } T \text{ in cell } (x, j-1)) \geq i+1$$

(since the entry of T in cell $(x, j-1)$ and the number i are integers). Combined with (13.94.20), this yields

$$(\text{the entry of } T \text{ in cell } (x, j-1)) = i+1.$$

Thus, the number $i+1$ appears in the $(j-1)$-th column of T (since the cell $(x, j-1)$ lies in the $(j-1)$-th column of T). In other words,

$$(\text{the number of entries } i+1 \text{ in the } (j-1)\text{-th column of } T) \geq 1. \tag{13.94.21}$$

On the other hand, the entries of T increase strictly top-to-bottom along columns. In particular, in every given column of T, the entries are distinct. Applied to the $(j-1)$-th column, this shows that the entries of the $(j-1)$-th column of T are distinct. In particular, for every $k \in \{1, 2, 3, \ldots\}$, the number k appears at most once in the $(j-1)$-th column of T. Applying this to $k = i$, we conclude that the number i appears at most once in the $(j-1)$-th column of T. That is,

$$(\text{the number of entries } i \text{ in the } (j-1)\text{-th column of } T) \leq 1. \tag{13.94.22}$$

Hence,

$$\begin{aligned}
&\left|\left\{\mathbf{c} \text{ is a cell of } T|_{\text{cols}\geq j} \ \mid\ \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\right\}\right| \\
&\leq |\{\mathbf{c} \text{ is a cell of } T \ \mid\ \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1; \text{ the cell } \mathbf{c} \text{ lies in one of the first } x \text{ rows of } T\}| \\
&= (\text{the number of entries } i+1 \text{ in the first } x \text{ rows of } T).
\end{aligned}$$

But

$$\begin{aligned}
\left(\text{cont}\left(T|_{\text{cols}\geq j}\right)\right)_{i+1} &= \left(\text{the number of entries } i+1 \text{ in } T|_{\text{cols}\geq j}\right) \\
&= \left|\left\{\mathbf{c} \text{ is a cell of } T|_{\text{cols}\geq j} \ \mid\ \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i+1\right\}\right| \\
&\leq (\text{the number of entries } i+1 \text{ in the first } x \text{ rows of } T),
\end{aligned}$$

qed.

[753] Here, we are using the following fact: If α, β and γ are three cells such that α lies southeast of the cell β, which in turn lies southeast of the cell γ, and if α and γ are cells of T, then β is also a cell of T. This can be easily derived from the fact that T has shape λ/μ.

Now, for every $k \in \{1, 2, 3, ...\}$ and $h \in \{1, 2, 3, ...\}$, we have

$$\begin{aligned}\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq k}\right)\right)_h &= \left|\left(T|_{\operatorname{cols}\geq k}\right)^{-1}(h)\right| = \left(\text{the number of entries } h \text{ in } T|_{\operatorname{cols}\geq k}\right) \\ &= \left(\text{the number of entries } h \text{ in the columns } k, k+1, k+2, ... \text{ of } T\right). \qquad (13.94.23)\end{aligned}$$

Applying this to $k = j$ and $h = i$, we obtain

$$\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i = \left(\text{the number of entries } i \text{ in the columns } j, j+1, j+2, ... \text{ of } T\right). \qquad (13.94.24)$$

But applying (13.94.23) to $k = j-1$ and $h = i$, we obtain

$$\begin{aligned}\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j-1}\right)\right)_i &= \left(\text{the number of entries } i \text{ in the columns } j-1, j, j+1, ... \text{ of } T\right) \\ &= \underbrace{\left(\text{the number of entries } i \text{ in the } (j-1)\text{-th column of } T\right)}_{\substack{\leq 1 \\ \text{(by (13.94.22))}}} \\ &\qquad + \underbrace{\left(\text{the number of entries } i \text{ in the columns } j, j+1, j+2, ... \text{ of } T\right)}_{\substack{=\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \\ \text{(by (13.94.24))}}} \\ &\leq 1 + \underbrace{\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i}_{\substack{<\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} \\ \text{(by (13.94.15))}}} < 1 + \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}.\end{aligned}$$

Since $\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j-1}\right)\right)_i$ and $1 + \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}$ are integers, this yields

$$\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j-1}\right)\right)_i \leq \left(1 + \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1}\right) - 1 = \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1},$$

so that

$$\begin{aligned}\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} &\geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j-1}\right)\right)_i \geq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j-1}\right)\right)_{i+1} \qquad \text{(by (13.94.14))} \\ &= \left(\text{the number of entries } i+1 \text{ in the columns } j-1, j, j+1, ... \text{ of } T\right) \\ &\qquad \text{(by (13.94.23), applied to } k = j-1 \text{ and } h = i+1\text{)} \\ &= \underbrace{\left(\text{the number of entries } i+1 \text{ in the } (j-1)\text{-th column of } T\right)}_{\substack{\geq 1 \\ \text{(by (13.94.21))}}} \\ &\qquad + \underbrace{\left(\text{the number of entries } i+1 \text{ in the columns } j, j+1, j+2, ... \text{ of } T\right)}_{\substack{=\left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} \\ \text{(since } \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} = \text{(the number of entries } i+1 \text{ in the columns } j,j+1,j+2,... \text{ of } T\text{)} \\ \text{(by (13.94.23), applied to } k=j \text{ and } h=i+1\text{))}}} \\ &\geq 1 + \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} > \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1},\end{aligned}$$

which is absurd. This contradiction proves that our assumption was wrong, and thus we have proven that $\mathbf{c}$ is a cell of $T|_{\operatorname{cols}\geq j}$.

Now, let us forget that we fixed $\mathbf{c}$. We thus have proven that if $\mathbf{c}$ is a cell of T such that the entry of T in $\mathbf{c}$ equals i and such that $\mathbf{c}$ lies in one of the first $x-1$ rows of T, then $\mathbf{c}$ is a cell of $T|_{\operatorname{cols}\geq j}$. Hence, the set

$$\{\mathbf{c} \text{ is a cell of } T \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\text{; the cell } \mathbf{c} \text{ lies in one of the first } x-1 \text{ rows of } T\}$$

is a subset of the set

$$\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\}.$$

Hence,

$$\begin{aligned}&|\{\mathbf{c} \text{ is a cell of } T \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\text{; the cell } \mathbf{c} \text{ lies in one of the first } x-1 \text{ rows of } T\}| \\ &\leq |\{\mathbf{c} \text{ is a cell of } T|_{\operatorname{cols}\geq j} \mid \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\}| \\ &= \left(\text{the number of entries } i \text{ in } T|_{\operatorname{cols}\geq j}\right) = \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i \qquad \text{(by (13.94.16))}.\end{aligned}$$

Since

$$\begin{aligned}&\left|\left\{\mathbf{c} \text{ is a cell of } T \ \mid \ \text{the entry of } T \text{ in } \mathbf{c} \text{ equals } i\text{; the cell } \mathbf{c} \text{ lies in one of the first } x-1 \text{ rows of } T\right\}\right| \\ &= (\text{the number of entries } i \text{ in the first } x-1 \text{ rows of } T),\end{aligned}$$

this rewrites as

$$(\text{the number of entries } i \text{ in the first } x-1 \text{ rows of } T) \leq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i .$$

Thus, (13.94.19) is proven. Now, (13.94.19) becomes

$$\begin{aligned}&(\text{the number of entries } i \text{ in the first } x-1 \text{ rows of } T) \\ &\leq \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_i < \left(\operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right)\right)_{i+1} \qquad (\text{by (13.94.15)}) \\ &\leq (\text{the number of entries } i+1 \text{ in the first } x \text{ rows of } T) \qquad (\text{by (13.94.18)}),\end{aligned}$$

which contradicts (13.94.17). This contradiction proves that our assumption was wrong. Hence, Assertion $\mathcal{C}_i$ must hold. We thus have proven the implication $\mathcal{D}_i \Longrightarrow \mathcal{C}_i$.

We have now proven the four implications $\mathcal{C}_i \Longrightarrow \mathcal{E}_i$, $\mathcal{E}_i \Longrightarrow \mathcal{F}_i$, $\mathcal{F}_i \Longrightarrow \mathcal{D}_i$ and $\mathcal{D}_i \Longrightarrow \mathcal{C}_i$. Combining them, we obtain the equivalence $\mathcal{C}_i \Longleftrightarrow \mathcal{D}_i \Longleftrightarrow \mathcal{E}_i \Longleftrightarrow \mathcal{F}_i$.

Now, let us forget that we fixed i. We thus have proven the equivalence $\mathcal{C}_i \Longleftrightarrow \mathcal{D}_i \Longleftrightarrow \mathcal{E}_i \Longleftrightarrow \mathcal{F}_i$ for every $i \in \{1, 2, 3, ...\}$. As we know, this shows that we have the equivalence $\mathcal{C} \Longleftrightarrow \mathcal{D} \Longleftrightarrow \mathcal{E} \Longleftrightarrow \mathcal{F}$, and this finishes the solution of Exercise 2.9.18(b).

13.95. **Solution to Exercise 2.9.20.** *Solution to Exercise 2.9.20.* (a) The solution to Exercise 2.9.20(a) is a rather straightforward adaptation of the solution of Exercise 2.9.18(b) that we gave above. We leave the details to the reader (who can also look them up in the LaTeX source code of this file, where they appear in a "commentedout" environment starting after this sentence).

(b) Exercise 2.9.20(a) yields the equivalence $\mathcal{C}^{(\kappa)} \Longleftrightarrow \mathcal{D}^{(\kappa)} \Longleftrightarrow \mathcal{E}^{(\kappa)} \Longleftrightarrow \mathcal{F}^{(\kappa)} \Longleftrightarrow \mathcal{G}^{(\kappa)}$. It thus remains to prove the equivalence $\mathcal{G}^{(\kappa)} \Longleftrightarrow \mathcal{H}^{(\kappa)}$. In order to do so, we must prove the implications $\mathcal{G}^{(\kappa)} \Longrightarrow \mathcal{H}^{(\kappa)}$ and $\mathcal{H}^{(\kappa)} \Longrightarrow \mathcal{G}^{(\kappa)}$.

The implication $\mathcal{H}^{(\kappa)} \Longrightarrow \mathcal{G}^{(\kappa)}$ is obvious (since we can just take the S whose existence is guaranteed by Assertion $\mathcal{H}^{(\kappa)}$, and set $\zeta = \tau$). It thus remains to prove the implication $\mathcal{G}^{(\kappa)} \Longrightarrow \mathcal{H}^{(\kappa)}$.

Proof of the implication $\mathcal{G}^{(\kappa)} \Longrightarrow \mathcal{H}^{(\kappa)}$*:* Assume that Assertion $\mathcal{G}^{(\kappa)}$ holds. We want to prove that Assertion $\mathcal{H}^{(\kappa)}$ holds.

We have assumed that Assertion $\mathcal{G}^{(\kappa)}$ holds. In other words, there exist a partition ζ and a column-strict tableau S of shape ζ/κ which satisfies the following property: For any positive integers i and j,

$$\left(\begin{array}{c}\text{the number of entries } i \text{ in the } j\text{-th row of } T \text{ equals} \\ \text{the number of entries } j \text{ in the } i\text{-th row of } S\end{array}\right). \tag{13.95.1}$$

Consider this ζ and this S.

For every $i \in \{1, 2, 3, \ldots\}$, we have

$$\begin{aligned}(\operatorname{cont} T)_i &= \left|T^{-1}(i)\right| \qquad (\text{by the definition of } \operatorname{cont} T) \\ &= (\text{the number of entries } i \text{ in } T) \\ &= \sum_{j=1}^{\infty} \underbrace{(\text{the number of entries } i \text{ in the } j\text{-th row of } T)}_{\substack{=(\text{the number of entries } j \text{ in the } i\text{-th row of } S) \\ (\text{by (13.95.1)})}} \\ &= \sum_{j=1}^{\infty} (\text{the number of entries } j \text{ in the } i\text{-th row of } S) \\ &= (\text{the number of entries in the } i\text{-th row of } S) \\ &= (\text{the length of the } i\text{-th row of the skew partition } \zeta/\kappa) \qquad (\text{since the tableau } S \text{ has shape } \zeta/\kappa) \\ &= \zeta_i - \kappa_i.\end{aligned}$$

Hence, for every $i \in \{1, 2, 3, \ldots\}$, we have

$$(\kappa + \operatorname{cont} T)_i = \kappa_i + \underbrace{(\operatorname{cont} T)_i}_{=\zeta_i - \kappa_i} = \kappa_i + (\zeta_i - \kappa_i) = \zeta_i.$$

In other words, $\kappa + \operatorname{cont} T = \zeta$, so that $\zeta = \kappa + \operatorname{cont} T = \tau$. But S is a column-strict tableau of shape ζ/κ. In other words, S is a column-strict tableau of shape τ/κ (since $\zeta = \tau$).

We thus have constructed a column-strict tableau S of shape τ/κ such that for any positive integers i and j, the property (13.95.1) holds. Therefore, Assertion $\mathcal{H}^{(\kappa)}$ holds. We thus have proven the implication $\mathcal{G}^{(\kappa)} \Longrightarrow \mathcal{H}^{(\kappa)}$. As we have said, this finishes the solution of Exercise 2.9.20(b).

13.96. **Solution to Exercise 2.9.21.** *Solution to Exercise 2.9.21.* (a) If T is a column-strict tableau of shape λ/μ, then we have the following chain of logical equivalences:

$$\begin{aligned} & \left(\text{for all } j \in \{1,2,3,\ldots\}, \text{ the weak composition } \kappa + \operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right) \text{ is a partition}\right) \\ \Longleftrightarrow\ & \left(\text{Assertion } \mathcal{C}^{(\kappa)} \text{ holds}\right) \qquad \left(\text{because this is how we defined Assertion } \mathcal{C}^{(\kappa)}\right) \\ \Longleftrightarrow\ & \left(\text{the five equivalent assertions } \mathcal{C}^{(\kappa)}, \mathcal{D}^{(\kappa)}, \mathcal{E}^{(\kappa)}, \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}\right) \end{aligned} \tag{13.96.1}$$

(because the five assertions $\mathcal{C}^{(\kappa)}$, $\mathcal{D}^{(\kappa)}$, $\mathcal{E}^{(\kappa)}$, $\mathcal{F}^{(\kappa)}$ and $\mathcal{G}^{(\kappa)}$ are equivalent (by Exercise 2.9.20(a))).

We can apply (2.6.3) to $\nu = \kappa$. As a result, we see that

$$s_\kappa s_{\lambda/\mu} = \sum_T s_{\kappa + \operatorname{cont} T},$$

where T runs through all column-strict tableaux of shape λ/μ with the property that for each $j = 1, 2, 3, \ldots$, the weak composition $\kappa + \operatorname{cont}(T|_{\operatorname{cols}\geq j})$ is a partition. In other words,

$$\begin{aligned} s_\kappa s_{\lambda/\mu} &= \underbrace{\sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{for all } j \in \{1,2,3,\ldots\}, \text{ the weak} \\ \text{composition } \kappa + \operatorname{cont}\left(T|_{\operatorname{cols}\geq j}\right) \\ \text{is a partition}}}_{\substack{= \sum \\ T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\, \mathcal{D}^{(\kappa)},\, \mathcal{E}^{(\kappa)},\, \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold} \\ \text{(because of the equivalence (13.96.1))}}} s_{\kappa + \operatorname{cont} T} && (13.96.2) \\ &= \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\, \mathcal{D}^{(\kappa)},\, \mathcal{E}^{(\kappa)},\, \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}}} s_{\kappa + \operatorname{cont} T}. && (13.96.3) \end{aligned}$$

In other words,

$$s_\kappa s_{\lambda/\mu} = \sum_T s_{\kappa + \operatorname{cont} T},$$

where the sum ranges over all column-strict tableaux T of shape λ/μ satisfying the five equivalent assertions $\mathcal{C}^{(\kappa)}$, $\mathcal{D}^{(\kappa)}$, $\mathcal{E}^{(\kappa)}$, $\mathcal{F}^{(\kappa)}$ and $\mathcal{G}^{(\kappa)}$ introduced in Exercise 2.9.20(a). This solves Exercise 2.9.21(a).

(b) If T is a column-strict tableau of shape λ/μ such that the five equivalent assertions $\mathcal{C}^{(\kappa)}$, $\mathcal{D}^{(\kappa)}$, $\mathcal{E}^{(\kappa)}$, $\mathcal{F}^{(\kappa)}$ and $\mathcal{G}^{(\kappa)}$ hold, then we have

$$\left(s_{\kappa + \operatorname{cont} T}, s_\tau\right)_\Lambda = \delta_{\tau, \kappa + \operatorname{cont} T} \tag{13.96.4}$$

[754].

[754] *Proof of (13.96.4):* We know that the basis $(s_\lambda)_{\lambda \in \operatorname{Par}}$ of Λ is orthonormal with respect to the Hall inner product. In other words, we have

$$\left(s_\alpha, s_\beta\right)_\Lambda = \delta_{\alpha,\beta} \tag{13.96.5}$$

But if T is a column-strict tableau of shape λ/μ satisfying $\tau = \kappa + \operatorname{cont} T$, then we have the following chain of logical equivalences:

$$\begin{aligned} &\left(\text{the five equivalent assertions } \mathcal{C}^{(\kappa)}, \mathcal{D}^{(\kappa)}, \mathcal{E}^{(\kappa)}, \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}\right) \\ \iff &\left(\text{the six equivalent assertions } \mathcal{C}^{(\kappa)}, \mathcal{D}^{(\kappa)}, \mathcal{E}^{(\kappa)}, \mathcal{F}^{(\kappa)}, \mathcal{G}^{(\kappa)} \text{ and } \mathcal{H}^{(\kappa)} \text{ hold}\right) \end{aligned} \tag{13.96.6}$$

(because the six assertions $\mathcal{C}^{(\kappa)}$, $\mathcal{D}^{(\kappa)}$, $\mathcal{E}^{(\kappa)}$, $\mathcal{F}^{(\kappa)}$, $\mathcal{G}^{(\kappa)}$ and $\mathcal{H}^{(\kappa)}$ are equivalent (by Exercise 2.9.20(b))).

Now, recall that $s_\mu^\perp (s_\lambda) = s_{\lambda/\mu}$. Applying this to κ and τ instead of μ and λ, we obtain $s_\kappa^\perp (s_\tau) = s_{\tau/\kappa}$.

Now, Proposition 2.8.2(i) (applied to $A = \Lambda$) shows that every $a \in \Lambda$, $f \in \Lambda$ and $g \in \Lambda$ satisfy $\left(g, f^\perp (a)\right)_\Lambda = (fg, a)_\Lambda$. We can apply this to $f = s_\kappa$, $g = s_{\lambda/\mu}$ and $a = s_\tau$. As a result, we obtain $\left(s_{\lambda/\mu}, s_\kappa^\perp (s_\tau)\right)_\Lambda = \left(s_\kappa s_{\lambda/\mu}, s_\tau\right)_\Lambda$. Since $s_\kappa^\perp (s_\tau) = s_{\tau/\kappa}$, this rewrites as follows:

$$\left(s_{\lambda/\mu}, s_{\tau/\kappa}\right)_\Lambda = \left(s_\kappa s_{\lambda/\mu}, s_\tau\right)_\Lambda . \tag{13.96.7}$$

for any $\alpha \in \operatorname{Par}$ and $\beta \in \operatorname{Par}$.

Now, let T be a column-strict tableau of shape λ/μ such that the five equivalent assertions $\mathcal{C}^{(\kappa)}$, $\mathcal{D}^{(\kappa)}$, $\mathcal{E}^{(\kappa)}$, $\mathcal{F}^{(\kappa)}$ and $\mathcal{G}^{(\kappa)}$ hold. Then, Assertion $\mathcal{C}^{(\kappa)}$ holds (since the five equivalent assertions $\mathcal{C}^{(\kappa)}$, $\mathcal{D}^{(\kappa)}$, $\mathcal{E}^{(\kappa)}$, $\mathcal{F}^{(\kappa)}$ and $\mathcal{G}^{(\kappa)}$ hold). In other words, for every positive integer j, the weak composition $\kappa + \operatorname{cont}\left(T|_{\operatorname{cols} \geq j}\right)$ is a partition. Applying this to $j = 1$, we conclude that the weak composition $\kappa + \operatorname{cont}\left(T|_{\operatorname{cols} \geq 1}\right)$ is a partition.

But $T|_{\operatorname{cols} \geq 1}$ is the subtableau which is the restriction of T to the union of its columns $1, 2, 3, \ldots$. In other words, $T|_{\operatorname{cols} \geq 1}$ is the whole tableau T. In other words, $T|_{\operatorname{cols} \geq 1} = T$.

Now, recall that $\kappa + \operatorname{cont}\left(T|_{\operatorname{cols} \geq 1}\right)$ is a partition. In other words, $\kappa + \operatorname{cont} T$ is a partition (since $T|_{\operatorname{cols} \geq 1} = T$). In other words, $\kappa + \operatorname{cont} T \in \operatorname{Par}$. Also, $\tau \in \operatorname{Par}$ (since τ is a partition). Thus, (13.96.5) (applied to $\alpha = \kappa + \operatorname{cont} T$ and $\beta = \tau$) shows that $\left(s_{\kappa + \operatorname{cont} T}, s_\tau\right)_\Lambda = \delta_{\kappa + \operatorname{cont} T, \tau} = \delta_{\tau, \kappa + \operatorname{cont} T}$. This proves (13.96.4).

Thus,

$$\begin{aligned}
\left(s_{\lambda/\mu}, s_{\tau/\kappa}\right)_\Lambda &= \left(s_\kappa s_{\lambda/\mu}, s_\tau\right)_\Lambda = \left(\sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}}} s_{\kappa+\operatorname{cont} T}, s_\tau \right)_\Lambda \qquad \text{(by (13.96.3))} \\
&= \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}}} \underbrace{\left(s_{\kappa+\operatorname{cont} T}, s_\tau\right)_\Lambda}_{\substack{=\delta_{\tau,\kappa+\operatorname{cont} T} \\ \text{(by (13.96.4))}}} \qquad \text{(since the Hall inner product is } \mathbf{k}\text{-bilinear)} \\
&= \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}}} \delta_{\tau,\kappa+\operatorname{cont} T} \\
&= \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}; \\ \tau=\kappa+\operatorname{cont} T}} \underbrace{\delta_{\tau,\kappa+\operatorname{cont} T}}_{\substack{=1 \\ \text{(since } \tau=\kappa+\operatorname{cont} T)}} + \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}; \\ \tau\neq\kappa+\operatorname{cont} T}} \underbrace{\delta_{\tau,\kappa+\operatorname{cont} T}}_{\substack{=0 \\ \text{(since } \tau\neq\kappa+\operatorname{cont} T)}} \\
&= \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}; \\ \tau=\kappa+\operatorname{cont} T}} 1 + \underbrace{\sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}; \\ \tau\neq\kappa+\operatorname{cont} T}} 0}_{=0} \\
&= \underbrace{\sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}; \\ \tau=\kappa+\operatorname{cont} T}}}_{\substack{= \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \tau=\kappa+\operatorname{cont} T; \\ \text{the five equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)} \text{ and } \mathcal{G}^{(\kappa)} \text{ hold}}} = \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \tau=\kappa+\operatorname{cont} T; \\ \text{the six equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)},\ \mathcal{G}^{(\kappa)} \text{ and } \mathcal{H}^{(\kappa)} \text{ hold}}} \\ \text{(by the equivalence (13.96.6))}}} 1 \\
&= \sum_{\substack{T \text{ is a column-strict tableau} \\ \text{of shape } \lambda/\mu; \\ \tau=\kappa+\operatorname{cont} T; \\ \text{the six equivalent assertions} \\ \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)},\ \mathcal{G}^{(\kappa)} \text{ and } \mathcal{H}^{(\kappa)} \text{ hold}}} 1 \\
&= \Big(\text{the number of all column-strict tableaux } T \text{ of shape } \lambda/\mu \text{ such that} \\
&\qquad \tau = \kappa + \operatorname{cont} T \text{ and such that the six equivalent} \\
&\qquad \text{assertions } \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)},\ \mathcal{G}^{(\kappa)} \text{ and } \mathcal{H}^{(\kappa)} \text{ hold}\Big) \\
&= \Big(\text{the number of all column-strict tableaux } T \text{ of shape } \lambda/\mu \text{ satisfying} \\
&\qquad \tau = \kappa + \operatorname{cont} T \text{ and also satisfying the six equivalent} \\
&\qquad \text{assertions } \mathcal{C}^{(\kappa)},\ \mathcal{D}^{(\kappa)},\ \mathcal{E}^{(\kappa)},\ \mathcal{F}^{(\kappa)},\ \mathcal{G}^{(\kappa)} \text{ and } \mathcal{H}^{(\kappa)}\Big).
\end{aligned}$$

This solves Exercise 2.9.21(b).

13.97. **Solution to Exercise 2.9.22.** *Solution to Exercise 2.9.22.* (a) We shall first prove that

$$\text{if } N \text{ has Jordan type } \lambda\text{, then every } k \in \mathbb{N} \text{ satisfies } \dim\left(\ker\left(N^k\right)\right) = \left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_k . \tag{13.97.1}$$

Proof of (13.97.1): Assume that N has Jordan type λ. Let $k \in \mathbb{N}$.

For each $m \in \mathbb{N}$, let J_m be $m \times m$-matrix $\begin{pmatrix} 0 & 1 & 0 & \cdots & 0 \\ 0 & 0 & 1 & \cdots & 0 \\ 0 & 0 & 0 & \cdots & 0 \\ \vdots & \vdots & \vdots & \ddots & \vdots \\ 0 & 0 & 0 & \cdots & 0 \end{pmatrix} \in \mathbb{K}^{m \times m}$. This is a Jordan block of size m corresponding to the eigenvalue 0 (when m is positive). For future use, we record the following simple fact:

$$\dim\left(\ker\left(J_m^k\right)\right) = \min\{m, k\} \tag{13.97.2}$$

for all $m \in \mathbb{N}$. [755].

Since N has Jordan type λ, the Jordan normal form of N has Jordan blocks of sizes $\lambda_1, \lambda_2, \lambda_3, \ldots$. Since the only eigenvalue of N is 0, this shows that the Jordan blocks of N are $J_{\lambda_1}, J_{\lambda_2}, J_{\lambda_3}, \ldots$ (or, more precisely, the nonempty matrices among $J_{\lambda_1}, J_{\lambda_2}, J_{\lambda_3}, \ldots$). In other words, N is similar to the block-diagonal matrix $J_\lambda := \begin{pmatrix} J_{\lambda_1} & 0 & 0 & \cdots \\ 0 & J_{\lambda_2} & 0 & \cdots \\ 0 & 0 & J_{\lambda_3} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}$. (This block-diagonal matrix J_λ is finite, since only finitely many λ_p are nonzero.) We can thus WLOG assume that N **is** this matrix J_λ (because replacing N by a matrix similar to N changes neither the dimension $\dim\left(\ker\left(N^k\right)\right)$ nor the Jordan type of N). Assume this. Thus, $N = J_\lambda = \begin{pmatrix} J_{\lambda_1} & 0 & 0 & \cdots \\ 0 & J_{\lambda_2} & 0 & \cdots \\ 0 & 0 & J_{\lambda_3} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}$, so that

$$N^k = \begin{pmatrix} J_{\lambda_1} & 0 & 0 & \cdots \\ 0 & J_{\lambda_2} & 0 & \cdots \\ 0 & 0 & J_{\lambda_3} & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}^k = \begin{pmatrix} J_{\lambda_1}^k & 0 & 0 & \cdots \\ 0 & J_{\lambda_2}^k & 0 & \cdots \\ 0 & 0 & J_{\lambda_3}^k & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix}$$

and therefore

$$\ker\left(N^k\right) = \ker \begin{pmatrix} J_{\lambda_1}^k & 0 & 0 & \cdots \\ 0 & J_{\lambda_2}^k & 0 & \cdots \\ 0 & 0 & J_{\lambda_3}^k & \cdots \\ \vdots & \vdots & \vdots & \ddots \end{pmatrix} \cong \bigoplus_{p \geq 1} \ker\left(J_{\lambda_p}^k\right),$$

whence

$$\dim\left(\ker\left(N^k\right)\right) = \dim\left(\bigoplus_{p\geq 1} \ker\left(J_{\lambda_p}^k\right)\right) = \sum_{p \geq 1} \underbrace{\dim\left(\ker\left(J_{\lambda_p}^k\right)\right)}_{\substack{=\min\{\lambda_p, k\} \\ \text{(by (13.97.2) (applied to } m=\lambda_p))}} = \sum_{p\geq 1} \min\{\lambda_p, k\}. \tag{13.97.3}$$

[755] *Proof sketch.* Let $m \in \mathbb{N}$. Let $(e_1, e_2, \ldots, e_m)$ be the standard basis of the $\mathbb{K}$-vector space $\mathbb{K}^m$. Now, it is easy to check that J_m^k is the $m \times m$-matrix whose (i,j)-th entry is $\begin{cases} 1, & \text{if } j = i + k; \\ 0, & \text{if } j \neq i + k \end{cases}$ for all $(i,j) \in \{1, 2, \ldots, m\}^2$. Hence, it is easy to see that $\ker\left(J_m^k\right)$ is the $\mathbb{K}$-linear span of the basis vectors e_j with $j \leq k$. These basis vectors are linearly independent and their number is $\min\{m, k\}$; therefore, (13.97.2) follows.

We are now going to prove that the right hand side of this equality is $(\lambda^t)_1 + (\lambda^t)_2 + \cdots + (\lambda^t)_k$. Indeed, let us use the *Iverson bracket notation*: For every assertion $\mathcal{A}$, we let $[\mathcal{A}]$ denote the integer $\begin{cases} 1, & \text{if } \mathcal{A} \text{ is true;} \\ 0, & \text{if } \mathcal{A} \text{ is false} \end{cases}$. (This integer is called the *truth value* of $\mathcal{A}$.)

Any two nonnegative integers u and v satisfy $\min\{u, v\} = \sum_{i=1}^{v} [i \leq u]$. Thus, $\min\{\lambda_p, k\} = \sum_{i=1}^{k} [i \leq \lambda_p]$ for every $p \in \{1, 2, 3, \ldots\}$. Hence, (13.97.3) becomes

$$\dim\left(\ker\left(N^k\right)\right) = \sum_{p\geq 1} \underbrace{\min\{\lambda_p, k\}}_{=\sum_{i=1}^{k}[i\leq\lambda_p]} = \sum_{p\geq 1}\sum_{i=1}^{k} [i \leq \lambda_p] = \sum_{i=1}^{k} \underbrace{\sum_{p\geq 1} [i \leq \lambda_p]}_{\substack{=|\{p\geq 1 \mid i\leq\lambda_p\}| \\ =|\{p\geq 1 \mid \lambda_p\geq i\}| \\ =|\{j\geq 1 \mid \lambda_j\geq i\}|=\left(\lambda^t\right)_i \\ (\text{by (2.2.7)})}}$$

$$= \sum_{i=1}^{k} \left(\lambda^t\right)_i = \left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_k .$$

This proves (13.97.1).

With (13.97.1), we have proven one direction of the equivalence that Exercise 2.9.22(a) requires us to prove. To prove the other direction, we need to show that

$$\text{if every } k \in \mathbb{N} \text{ satisfies } \dim\left(\ker\left(N^k\right)\right) = \left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_k, \text{ then } N \text{ has Jordan type } \lambda. \tag{13.97.4}$$

Proof of (13.97.4): Assume that every $k \in \mathbb{N}$ satisfies $\dim\left(\ker\left(N^k\right)\right) = (\lambda^t)_1 + (\lambda^t)_2 + \cdots + (\lambda^t)_k$. Let μ be the Jordan type of N. Then, (13.97.1) (applied to μ instead of λ) shows that every $k \in \mathbb{N}$ satisfies $\dim\left(\ker\left(N^k\right)\right) = (\mu^t)_1 + (\mu^t)_2 + \cdots + (\mu^t)_k$. Hence, every $k \in \mathbb{N}$ satisfies

$$\left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_k = \dim\left(\ker\left(N^k\right)\right) = \left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_k . \tag{13.97.5}$$

Applying (13.97.5) to $k-1$ instead of k, and subtracting the result from (13.97.5), we obtain

$$\left(\mu^t\right)_k = \left(\lambda^t\right)_k \qquad \text{for every positive integer } k.$$

Hence, $\mu^t = \lambda^t$, so that $\mu = \lambda$. Thus, N has Jordan type $\mu = \lambda$. This proves (13.97.4), and thus the solution of Exercise 2.9.22(a) is complete.

Before we come to the solution of Exercise 2.9.22(b), let us show a linear-algebraic lemma:

Lemma 13.97.1. *Let W be a finite-dimensional $\mathbb{K}$-vector space. Let A and B be $\mathbb{K}$-vector subspaces of W. Let $f \in \operatorname{End} W$ be such that $f(A) \subset A$ and $f(B) \subset B$. For any $(i, j) \in \mathbb{N}^2$, let us define a nonnegative integer $w_{i,j}$ by $w_{i,j} = \dim\left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right)$.*

(a) For any $(i, j) \in \{1, 2, 3, \ldots\}^2$, we have $w_{i,j} + w_{i-1,j-1} \geq w_{i,j-1} + w_{i-1,j}$.

(b) For any $(i, j) \in \mathbb{N} \times \{1, 2, 3, \ldots\}$, we have $w_{i+1,j+1} - w_{i+1,j} \leq w_{i,j} - w_{i,j-1}$.

(c) For any $(i, j) \in \{1, 2, 3, \ldots\} \times \mathbb{N}$, we have $w_{i+1,j+1} - w_{i,j+1} \leq w_{i,j} - w_{i-1,j}$.

(d) If $i \in \{1, 2, 3, \ldots\}$ and $j \in \mathbb{N}$ are such that $i > \dim W$, then $w_{i,j} = w_{i-1,j}$.

(e) If $j \in \{1, 2, 3, \ldots\}$ and $i \in \mathbb{N}$ are such that $j > \dim W$, then $w_{i,j} = w_{i,j-1}$.

(f) Assume that f is nilpotent. For every $j \in \mathbb{N}$, we have $\sum_{i=1}^{\infty} (w_{i,j} - w_{i-1,j}) = \dim\left(\left(f^j\right)^{-1}(B)\right) - \dim\left(A \cap \left(f^j\right)^{-1}(B)\right)$. (In particular, the sum $\sum_{i=1}^{\infty} (w_{i,j} - w_{i-1,j})$ converges with respect to the discrete topology, i.e., all but finitely many of its terms are 0.)

(g) Assume that f is nilpotent. For every $i \in \mathbb{N}$, we have $\sum_{j=1}^{\infty} (w_{i,j} - w_{i,j-1}) = \dim\left(\left(f^i\right)^{-1}(A)\right) - \dim\left(\left(f^i\right)^{-1}(A) \cap B\right)$. (In particular, the sum $\sum_{j=1}^{\infty} (w_{i,j} - w_{i,j-1})$ converges with respect to the discrete topology, i.e., all but finitely many of its terms are 0.)

Proof of Lemma 13.97.1. Notice first that $\Big(\underbrace{f^0}_{=\mathrm{id}}\Big)^{-1}(A) = \mathrm{id}^{-1}(A) = A$ and $A = \left(f^0\right)^{-1}(A) \subset \left(f^1\right)^{-1}(A) \subset \left(f^2\right)^{-1}(A) \subset \cdots$ (since $f(A) \subset A$) and $B = \left(f^0\right)^{-1}(B) \subset \left(f^1\right)^{-1}(B) \subset \left(f^2\right)^{-1}(B) \subset \cdots$ (similarly).

(a) Let $(i,j) \in \{1,2,3,\ldots\}^2$. We need to prove that $w_{i,j} + w_{i-1,j-1} \geq w_{i,j-1} + w_{i-1,j}$. In other words, we need to prove that $w_{i,j} - w_{i,j-1} \geq w_{i-1,j} - w_{i-1,j-1}$. Since

$$\begin{aligned} w_{i,j} - w_{i,j-1} &= \dim\left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) - \dim\left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right) \\ &\qquad \left(\text{by the definitions of } w_{i,j} \text{ and } w_{i,j-1}\right) \\ &= \dim\left(\left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right)\right) \\ &\qquad \left(\text{since } \left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B) \subset \left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) \end{aligned} \tag{13.97.6}$$

and

$$w_{i-1,j} - w_{i-1,j-1} = \dim\left(\left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right)\right)$$

(by the same argument as (13.97.6), only with $i-1$ instead of i), this is equivalent to showing that

$$\begin{aligned} &\dim\left(\left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right)\right) \\ &\geq \dim\left(\left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right)\right). \end{aligned}$$

This will clearly be achieved if we can construct a $\mathbb{K}$-linear injection

$$\begin{aligned} &\left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right) \\ &\to \left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right). \end{aligned}$$

Here is how to construct it: Let ι denote the canonical inclusion $\left(f^{i-1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B) \to \left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)$. Then, ι restricts to an inclusion $\left(f^{i-1}\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B) \to \left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)$, and so gives rise to a map

$$\begin{aligned} &\left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^{i-1}\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right) \\ &\to \left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right). \end{aligned}$$

This map is injective because $\iota^{-1}\left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right) = \left(f^{i-1}\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)$, and thus we have found our $\mathbb{K}$-linear injection. Lemma 13.97.1(a) is proven.

(b) Let $(i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}$. We need to prove that $w_{i+1,j+1} - w_{i+1,j} \leq w_{i,j} - w_{i,j-1}$. Due to (13.97.6) and due to

$$w_{i+1,j+1} - w_{i+1,j} = \dim\left(\left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^{j+1}\right)^{-1}(B)\right) / \left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right)\right)$$

(this follows by the same arguments as (13.97.6), only with i and j replaced by $i+1$ and $j+1$), this is equivalent to showing that

$$\begin{aligned} &\dim\left(\left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^{j+1}\right)^{-1}(B)\right) / \left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right)\right) \\ &\leq \dim\left(\left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right)\right). \end{aligned}$$

This will clearly be achieved if we can construct a $\mathbb{K}$-linear injection

$$\begin{aligned} &\left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^{j+1}\right)^{-1}(B)\right) / \left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) \\ &\to \left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right). \end{aligned}$$

Here is how this can be done: The map f restricts to a map $\varphi : \left(f^{i+1}\right)^{-1}(A) \cap \left(f^{j+1}\right)^{-1}(B) \to \left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)$, which further restricts to a map $\left(f^{i+1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B) \to \left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)$. Hence, φ gives rise to a map

$$\begin{aligned} &\left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^{j+1}\right)^{-1}(B)\right) / \left(\left(f^{i+1}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) \\ &\to \left(\left(f^i\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)\right) / \left(\left(f^i\right)^{-1}(A) \cap \left(f^{j-1}\right)^{-1}(B)\right), \end{aligned}$$

which is injective because

$$\begin{aligned}\varphi^{-1}\left(\left(f^{i}\right)^{-1}(A)\cap\left(f^{j-1}\right)^{-1}(B)\right) &= f^{-1}\left(\left(f^{i}\right)^{-1}(A)\cap\left(f^{j-1}\right)^{-1}(B)\right)\\ &= \underbrace{f^{-1}\left(\left(f^{i}\right)^{-1}(A)\right)}_{=\left(f^{i+1}\right)^{-1}(A)}\cap\underbrace{f^{-1}\left(\left(f^{j-1}\right)^{-1}(B)\right)}_{=\left(f^{j}\right)^{-1}(B)} = \left(f^{i+1}\right)^{-1}(A)\cap\left(f^{j}\right)^{-1}(B).\end{aligned}$$

Thus, we have found our $\mathbb{K}$-linear injection. Lemma 13.97.1(b) is proven.

(c) The proof of Lemma 13.97.1(c) is analogous to our above proof of Lemma 13.97.1(b) (one merely has to interchange A with B and i with j).

(d) We have

$$\left(f^{0}\right)^{-1}(A)\subset\left(f^{1}\right)^{-1}(A)\subset\cdots\subset\left(f^{\dim W+1}\right)^{-1}(A)$$

and therefore

$$\dim\left(\left(f^{0}\right)^{-1}(A)\right)\leq\dim\left(\left(f^{1}\right)^{-1}(A)\right)\leq\cdots\leq\dim\left(\left(f^{\dim W+1}\right)^{-1}(A)\right).$$

This latter chain of inequalities contains $\dim W+1$ inequality signs, but only at most $\dim W$ of them can be strict (because each $\dim\left(\left(f^{k}\right)^{-1}(A)\right)$ is an integer between 0 and $\dim W$ inclusive[756], and a sequence of $\dim W+2$ integers between 0 and $\dim W$ cannot strictly increase). Thus, at least one of the inequality signs is an equality. That is, there exists an $I\in\{1,2,\ldots,\dim W+1\}$ such that $\dim\left(\left(f^{I-1}\right)^{-1}(A)\right)=\dim\left(\left(f^{I}\right)^{-1}(A)\right)$. Consider this I.

Since $\dim\left(\left(f^{I-1}\right)^{-1}(A)\right)=\dim\left(\left(f^{I}\right)^{-1}(A)\right)$ and $\left(f^{I-1}\right)^{-1}(A)\subset\left(f^{I}\right)^{-1}(A)$, we must have

$$\left(f^{I-1}\right)^{-1}(A)=\left(f^{I}\right)^{-1}(A). \qquad (13.97.7)$$

From here, it is easy to see that

$$\left(f^{i-1}\right)^{-1}(A)=\left(f^{i}\right)^{-1}(A)\qquad\text{for every } i\in\{1,2,3,\ldots\} \text{ satisfying } i>\dim W.$$

[757]

Thus, for every $i\in\{1,2,3,\ldots\}$ satisfying $i>\dim W$, we have

$$\begin{aligned}w_{i-1,j} &= \dim\left(\underbrace{\left(f^{i-1}\right)^{-1}(A)}_{=\left(f^{i}\right)^{-1}(A)}\cap\left(f^{j}\right)^{-1}(B)\right)\qquad\text{(by the definition of } w_{i-1,j}\text{)}\\ &= \dim\left(\left(f^{i}\right)^{-1}(A)\cap\left(f^{j}\right)^{-1}(B)\right)=w_{i,j}\qquad\text{for all } j\in\mathbb{N}.\end{aligned}$$

Thus, if $i\in\{1,2,3,\ldots\}$ and $j\in\mathbb{N}$ are such that $i>\dim W$, then $w_{i-1,j}=w_{i-1,j}$. This proves Lemma 13.97.1(d).

(e) The proof of Lemma 13.97.1(e) is analogous to our above proof of Lemma 13.97.1(d) (one merely has to interchange A with B and i with j).

[756] since $\left(f^{k}\right)^{-1}(A)$ is a subspace of the finite-dimensional $\mathbb{K}$-vector space W

[757] *Proof.* Let $i\in\{1,2,3,\ldots\}$ be such that $i>\dim W$. Thus, $i\geq\dim W+1$. But $I\leq\dim W+1$ (since $I\in\{1,2,\ldots,\dim W+1\}$) and thus $i\geq\dim W+1\geq I$. Hence, there exists some $k\in\mathbb{N}$ such that $i=I+k$. Consider this k. Since $i=I+k$, we have $i-1=I+k-1=(I-1)+k$, so that $f^{i-1}=f^{(I-1)+k}=f^{I-1}\circ f^{k}$ and thus $\left(f^{i-1}\right)^{-1}(A)=\left(f^{I-1}\circ f^{k}\right)^{-1}(A)=\left(f^{k}\right)^{-1}\left(\left(f^{I-1}\right)^{-1}(A)\right)$. Similarly, $\left(f^{i}\right)^{-1}(A)=\left(f^{k}\right)^{-1}\left(\left(f^{I}\right)^{-1}(A)\right)$. Now,

$$\left(f^{i-1}\right)^{-1}(A)=\left(f^{k}\right)^{-1}\left(\underbrace{\left(f^{I-1}\right)^{-1}(A)}_{\substack{=\left(f^{I}\right)^{-1}(A)\\ \text{(by (13.97.7))}}}\right)=\left(f^{k}\right)^{-1}\left(\left(f^{I}\right)^{-1}(A)\right)=\left(f^{i}\right)^{-1}(A),$$

qed.

(f) Let $j \in \mathbb{N}$. We have

$$\sum_{i=1}^{\infty} (w_{i,j} - w_{i-1,j}) = \sum_{i=1}^{\dim W} (w_{i,j} - w_{i-1,j}) + \sum_{i=\dim W+1}^{\infty} \left(\underbrace{w_{i,j}}_{\substack{=w_{i-1,j} \\ \text{(by Lemma 13.97.1(d),} \\ \text{since } i>\dim W)}} - w_{i-1,j} \right)$$

$$= \sum_{i=1}^{\dim W} (w_{i,j} - w_{i-1,j}) + \sum_{i=\dim W+1}^{\infty} \underbrace{(w_{i-1,j} - w_{i-1,j})}_{=0} = \sum_{i=1}^{\dim W} (w_{i,j} - w_{i-1,j}) + \underbrace{\sum_{i=\dim W+1}^{\infty} 0}_{=0}$$

$$= \sum_{i=1}^{\dim W} (w_{i,j} - w_{i-1,j}) = w_{\dim W,j} - w_{0,j} \qquad \text{(by the telescope principle)}. \tag{13.97.8}$$

Now, we are going to prove that $w_{\dim W,j} = \dim \left(\left(f^j\right)^{-1}(B) \right)$ and $w_{0,j} = \dim \left(A \cap \left(f^j\right)^{-1}(B) \right)$.

Indeed, it is well-known that if g is any nilpotent endomorphism of a finite-dimensional vector space V, then $g^{\dim V} = 0$. Applied to $g = f$ and $V = W$, this yields $f^{\dim W} = 0$, and thus $f^{\dim W}(W) = 0(W) = 0 \subset A$, whence $W \subset \left(f^{\dim W}\right)^{-1}(A)$, so that $\left(f^{\dim W}\right)^{-1}(A) = W$. Hence,

$$\underbrace{\left(f^{\dim W}\right)^{-1}(A)}_{=W} \cap \left(f^j\right)^{-1}(B) = W \cap \left(f^j\right)^{-1}(B) = \left(f^j\right)^{-1}(B)$$

(since $\left(f^j\right)^{-1}(B) \subset W$). Now, the definition of $w_{\dim W,j}$ yields

$$w_{\dim W,j} = \dim \left(\underbrace{\left(f^{\dim W}\right)^{-1}(A) \cap \left(f^j\right)^{-1}(B)}_{=(f^j)^{-1}(B)} \right) = \dim \left(\left(f^j\right)^{-1}(B) \right).$$

Also, the definition of $w_{0,j}$ yields

$$w_{0,j} = \dim \left(\left(\underbrace{f^0}_{=\mathrm{id}} \right)^{-1}(A) \cap \left(f^j\right)^{-1}(B) \right) = \dim \left(\underbrace{\mathrm{id}^{-1}(A)}_{=A} \cap \left(f^j\right)^{-1}(B) \right) = \dim \left(A \cap \left(f^j\right)^{-1}(B) \right).$$

Hence, (13.97.8) becomes

$$\sum_{i=1}^{\infty} (w_{i,j} - w_{i-1,j}) = \underbrace{w_{\dim W,j}}_{=\dim\left((f^j)^{-1}(B)\right)} - \underbrace{w_{0,j}}_{=\dim\left(A\cap(f^j)^{-1}(B)\right)} = \dim \left(\left(f^j\right)^{-1}(B) \right) - \dim \left(A \cap \left(f^j\right)^{-1}(B) \right).$$

This proves Lemma 13.97.1(f).

(g) The proof of Lemma 13.97.1(g) is analogous to our above proof of Lemma 13.97.1(f) (one merely has to interchange A with B and i with j). □

(b) Assume that $\mathbb{Z}$ is a subring of $\mathbf{k}$.

For any $(i,j) \in \mathbb{N}^2$, let us define a nonnegative integer $a_{i,j}$ by

$$a_{i,j} = \dim \left(\left(f^i\right)^{-1}(U) \cap \ker\left(f^j\right) \right).$$

Furthermore, for every $(i,j) \in \{1,2,3,\ldots\}^2$, let us define an integer $b_{i,j}$ by

$$b_{i,j} = a_{i,j} - a_{i,j-1} - a_{i-1,j} + a_{i-1,j-1}.$$

We first observe that

$$a_{i,0} = 0 \qquad \text{for every } i \in \mathbb{N}. \tag{13.97.9}$$

[758] Furthermore,

$$a_{0,j} = \left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_j \qquad \text{for every } j \in \mathbb{N}. \tag{13.97.10}$$

[759] Thus,

$$a_{0,j} - a_{0,j-1} = \left(\mu^t\right)_j \qquad \text{for every } j \in \{1,2,3,\ldots\}. \tag{13.97.11}$$

[760] Moreover, every $(i,j) \in \mathbb{N}^2$ satisfies

$$a_{i,j} = \dim\left(\left(f^i\right)^{-1}(U) \cap \underbrace{\ker\left(f^j\right)}_{=\left(f^j\right)^{-1}(0)} \right) = \dim\left(\left(f^i\right)^{-1}(U) \cap \left(f^j\right)^{-1}(0) \right).$$

Hence, Lemma 13.97.1(a) (applied to $W = V$, $A = U$, $B = 0$ and $w_{i,j} = a_{i,j}$) shows that for any $(i,j) \in \{1,2,3,\ldots\}^2$, we have $a_{i,j} + a_{i-1,j-1} \geq a_{i,j-1} + a_{i-1,j}$. In other words, for any $(i,j) \in \{1,2,3,\ldots\}^2$, we have $a_{i,j} - a_{i,j-1} - a_{i-1,j} + a_{i-1,j-1} \geq 0$. In other words, for any $(i,j) \in \{1,2,3,\ldots\}^2$, we have

$$b_{i,j} \geq 0 \tag{13.97.12}$$

(since $b_{i,j} = a_{i,j} - a_{i,j-1} - a_{i-1,j} + a_{i-1,j-1}$). Thus, $b_{i,j}$ is a nonnegative integer for every two positive integers i and j. Moreover,

$$b_{i,j} = 0 \qquad \text{for all but finitely many pairs } (i,j). \tag{13.97.13}$$

[758] *Proof of (13.97.9):* For every $i \in \mathbb{N}$, the definition of $a_{i,0}$ yields $a_{i,0} = \dim\left(\left(f^i\right)^{-1}(U) \cap \underbrace{\ker\left(f^0\right)}_{=\ker(\mathrm{id})=0} \right) = \dim \underbrace{\left(\left(f^i\right)^{-1}(U) \cap 0 \right)}_{=0} = \dim 0 = 0$, qed.

[759] *Proof of (13.97.10):* Let $j \in \mathbb{N}$. We can represent the endomorphism $f \mid U$ of U as a $k \times k$-matrix $G \in \mathbb{K}^{k \times k}$ for $k = \dim U$. This $k \times k$-matrix G is nilpotent (since $f \mid U$ is nilpotent) and has Jordan type μ (since $f \mid U$ has Jordan type μ). But Exercise 2.9.22(a) (applied to k, G and μ instead of n, N and λ) shows that G has Jordan type μ if and only if every $k \in \mathbb{N}$ satisfies $\dim\left(\ker\left(G^k\right)\right) = \left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_k$. Since we know that G has Jordan type μ, we thus conclude that every $k \in \mathbb{N}$ satisfies $\dim\left(\ker\left(G^k\right)\right) = \left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_k$. Applied to $k = j$, this yields $\dim\left(\ker\left(G^j\right)\right) = \left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_j$.

Since the matrix G represents the endomorphism $f \mid U$, we have

$$\dim\left(\ker\left(G^j\right)\right) = \dim\left(\underbrace{\ker\left((f \mid U)^j \right)}_{=U \cap \ker\left(f^j\right)} \right) = \dim\left(U \cap \ker\left(f^j\right)\right).$$

Compared with $\dim\left(\ker\left(G^j\right)\right) = \left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_j$, this yields

$$\dim\left(U \cap \ker\left(f^j\right)\right) = \left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_j.$$

Now, the definition of $a_{0,j}$ yields

$$a_{0,j} = \dim\left(\left(\underbrace{f^0}_{=\mathrm{id}} \right)^{-1} (U) \cap \ker\left(f^j\right) \right) = \dim\left(\underbrace{\mathrm{id}^{-1}(U)}_{=U} \cap \ker\left(f^j\right) \right) = \dim\left(U \cap \ker\left(f^j\right)\right) = \left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_j.$$

This proves (13.97.10).

[760] *Proof of (13.97.11):* For every $j \in \{1,2,3,\ldots\}$, we have

$$\underbrace{a_{0,j}}_{\substack{=\left(\mu^t\right)_1+\left(\mu^t\right)_2+\cdots+\left(\mu^t\right)_j \\ \text{(by (13.97.10))}}} - \underbrace{a_{0,j-1}}_{\substack{=\left(\mu^t\right)_1+\left(\mu^t\right)_2+\cdots+\left(\mu^t\right)_{j-1} \\ \text{(by (13.97.10), applied to} \\ j-1 \text{ instead of } j)}} = \left(\left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_j \right) - \left(\left(\mu^t\right)_1 + \left(\mu^t\right)_2 + \cdots + \left(\mu^t\right)_{j-1} \right) = \left(\mu^t\right)_j,$$

qed.

[761] Also,

$$\left(\mu^t\right)_j + \left(b_{1,j} + b_{2,j} + \cdots + b_{i,j}\right) = a_{i,j} - a_{i,j-1} \qquad \text{for every } (i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}. \tag{13.97.15}$$

[762]

Now, Exercise 2.9.18(a) (applied to μ^t instead of μ) yields that the following two assertions are equivalent[763]:

- *Assertion $\mathcal{A}'$:* There exist a partition γ and a column-strict tableau T of shape γ/μ^t such that all $(i,j) \in \{1,2,3,\ldots\}^2$ satisfy

$$b_{i,j} = (\text{the number of all entries } i \text{ in the } j\text{-th row of } T). \tag{13.97.16}$$

- *Assertion $\mathcal{B}'$:* The inequality

$$\left(\mu^t\right)_{j+1} + \left(b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}\right) \leq \left(\mu^t\right)_j + \left(b_{1,j} + b_{2,j} + \cdots + b_{i,j}\right) \tag{13.97.17}$$

  holds for all $(i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}$.

We shall now prove that Assertion $\mathcal{B}'$ holds. Indeed, any $(i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}$ satisfies

$$\begin{aligned}
&\left(\mu^t\right)_{j+1} + \left(b_{1,j+1} + b_{2,j+1} + \cdots + b_{i+1,j+1}\right) \\
&= a_{i+1,j+1} - a_{i+1,j} \qquad (\text{by (13.97.15), applied to } i+1 \text{ and } j+1 \text{ instead of } i \text{ and } j) \\
&\leq a_{i,j} - a_{i,j-1} \qquad (\text{by Lemma 13.97.1(b) (applied to } W = V,\ A = U,\ B = 0 \text{ and } w_{i,j} = a_{i,j})) \\
&= \left(\mu^t\right)_j + \left(b_{1,j} + b_{2,j} + \cdots + b_{i,j}\right) \qquad (\text{by (13.97.15)}).
\end{aligned}$$

Thus, Assertion $\mathcal{B}'$ holds. Since Assertions $\mathcal{A}'$ and $\mathcal{B}'$ are equivalent, this yields that Assertion $\mathcal{A}'$ also holds. In other words, there exist a partition γ and a column-strict tableau T of shape γ/μ^t such that all $(i,j) \in \{1,2,3,\ldots\}^2$ satisfy (13.97.16). Let us consider this γ and this T.

We shall soon see that $\gamma = \lambda^t$ and $\operatorname{cont} T = \nu^t$. Let us first prepare for this. We have

$$\dim\left(\left(f^j\right)^{-1}(0)\right) = \left(\lambda^t\right)_1 + \left(\lambda^t\right)_2 + \cdots + \left(\lambda^t\right)_j \qquad \text{for every } j \in \mathbb{N}. \tag{13.97.18}$$

[761] *Proof of (13.97.13):* Lemma 13.97.1(d) (applied to $W = V$, $A = U$, $B = 0$ and $w_{i,j} = a_{i,j}$) shows that if $i \in \{1,2,3,\ldots\}$ and $j \in \mathbb{N}$ are such that $i > \dim V$, then

$$a_{i,j} = a_{i-1,j}. \tag{13.97.14}$$

Lemma 13.97.1(e) (applied to $W = V$, $A = U$, $B = 0$ and $w_{i,j} = a_{i,j}$) shows that if $j \in \{1,2,3,\ldots\}$ and $i \in \mathbb{N}$ satisfy $j > \dim V$, then $a_{i,j} = a_{i,j-1}$.

Now, let $(i,j) \in \{1,2,3,\ldots\}^2$. If $i > \dim V$, then

$$b_{i,j} = \underbrace{a_{i,j}}_{\substack{=a_{i-1,j} \\ \text{(by (13.97.14),} \\ \text{since } i>\dim V)}} - \underbrace{a_{i,j-1}}_{\substack{=a_{i-1,j-1} \\ \text{(by (13.97.14) (applied to} \\ j-1 \text{ instead of } j), \\ \text{since } i>\dim V)}} - a_{i-1,j} + a_{i-1,j-1} = a_{i-1,j} - a_{i-1,j-1} - a_{i-1,j} + a_{i-1,j-1} = 0.$$

Similarly, $b_{i,j} = 0$ if $j > \dim V$. Hence, we see that $b_{i,j} = 0$ if we have $i > \dim V$ or $j > \dim V$ (or both). Thus, $b_{i,j} = 0$ for all but finitely many pairs (i,j) (because all but finitely many pairs (i,j) satisfy $i > \dim V$ or $j > \dim V$). This proves (13.97.13).

[762] *Proof of (13.97.15):* Let $(i,j) \in \mathbb{N} \times \{1,2,3,\ldots\}$. Then,

$$\begin{aligned}
b_{1,j} + b_{2,j} + \cdots + b_{i,j} &= \sum_{k=1}^{i} \underbrace{b_{k,j}}_{\substack{=a_{k,j} - a_{k,j-1} - a_{k-1,j} + a_{k-1,j-1} \\ \text{(by the definition of } b_{k,j})}} = \sum_{k=1}^{i} \underbrace{\left(a_{k,j} - a_{k,j-1} - a_{k-1,j} + a_{k-1,j-1}\right)}_{=\left(a_{k,j} - a_{k,j-1}\right) - \left(a_{k-1,j} - a_{k-1,j-1}\right)} \\
&= \sum_{k=1}^{i} \left(\left(a_{k,j} - a_{k,j-1}\right) - \left(a_{k-1,j} - a_{k-1,j-1}\right)\right) = \left(a_{i,j} - a_{i,j-1}\right) - \underbrace{\left(a_{0,j} - a_{0,j-1}\right)}_{\substack{=\left(\mu^t\right)_j \\ \text{(by (13.97.11))}}} \\
&\qquad (\text{by the telescope principle}) \\
&= \left(a_{i,j} - a_{i,j-1}\right) - \left(\mu^t\right)_j,
\end{aligned}$$

and thus $\left(\mu^t\right)_j + \left(b_{1,j} + b_{2,j} + \cdots + b_{i,j}\right) = a_{i,j} - a_{i,j-1}$, qed.

[763] The partition that we call γ in Assertion $\mathcal{A}'$ is the partition that was called λ in Assertion $\mathcal{A}$.

[764] From here, it is easy to see that

$$\dim\left(\left(f^{j}\right)^{-1}(0)\right)-\dim\left(\left(f^{j-1}\right)^{-1}(0)\right)=\left(\lambda^{t}\right)_{j} \qquad \text{for every } j\in\{1,2,3,\ldots\}. \tag{13.97.19}$$

[765] Now, for every $j\in\{1,2,3,\ldots\}$, we have

$$(\text{the number of all entries in the } j\text{-th row of } T)=\gamma_j-\left(\mu^{t}\right)_{j}$$

(since T has shape γ/μ^t), so that

$$\begin{aligned}
\gamma_j-\left(\mu^{t}\right)_{j} &= (\text{the number of all entries in the } j\text{-th row of } T)\\
&=\sum_{i=1}^{\infty}\underbrace{(\text{the number of all entries } i \text{ in the } j\text{-th row of } T)}_{\substack{=b_{i,j}\\ \text{(by (13.97.16))}}}=\sum_{i=1}^{\infty}\underbrace{b_{i,j}}_{=a_{i,j}-a_{i,j-1}-a_{i-1,j}+a_{i-1,j-1}}\\
&=\sum_{i=1}^{\infty}\underbrace{\left(a_{i,j}-a_{i,j-1}-a_{i-1,j}+a_{i-1,j-1}\right)}_{=\left(a_{i,j}-a_{i-1,j}\right)-\left(a_{i,j-1}-a_{i-1,j-1}\right)}=\sum_{i=1}^{\infty}\left(\left(a_{i,j}-a_{i-1,j}\right)-\left(a_{i,j-1}-a_{i-1,j-1}\right)\right)\\
&=\underbrace{\sum_{i=1}^{\infty}\left(a_{i,j}-a_{i-1,j}\right)}_{\substack{=\dim\left(\left(f^{j}\right)^{-1}(0)\right)-\dim\left(U\cap\left(f^{j}\right)^{-1}(0)\right)\\ \text{(by Lemma 13.97.1(f), applied to}\\ W=V,\ A=U,\ B=0 \text{ and } w_{i,j}=a_{i,j})}}-\underbrace{\sum_{i=1}^{\infty}\left(a_{i,j-1}-a_{i-1,j-1}\right)}_{\substack{=\dim\left(\left(f^{j-1}\right)^{-1}(0)\right)-\dim\left(U\cap\left(f^{j-1}\right)^{-1}(0)\right)\\ \text{(by Lemma 13.97.1(f), applied to}\\ V,\ U,\ 0,\ a_{i,j} \text{ and } j-1 \text{ instead of } W,\ A,\ B,\ w_{i,j} \text{ and } j)}}\\
&=\left(\dim\left(\left(f^{j}\right)^{-1}(0)\right)-\dim\left(U\cap\left(f^{j}\right)^{-1}(0)\right)\right)-\left(\dim\left(\left(f^{j-1}\right)^{-1}(0)\right)-\dim\left(U\cap\left(f^{j-1}\right)^{-1}(0)\right)\right)\\
&=\underbrace{\left(\dim\left(\left(f^{j}\right)^{-1}(0)\right)-\dim\left(\left(f^{j-1}\right)^{-1}(0)\right)\right)}_{\substack{=\left(\lambda^{t}\right)_{j}\\ \text{(by (13.97.19))}}}-\left(\dim\left(U\cap\left(f^{j}\right)^{-1}(0)\right)-\dim\left(U\cap\left(f^{j-1}\right)^{-1}(0)\right)\right)\\
&=\left(\lambda^{t}\right)_{j}-\left(\dim\left(U\cap\left(f^{j}\right)^{-1}(0)\right)-\dim\left(U\cap\left(f^{j-1}\right)^{-1}(0)\right)\right).
\end{aligned}$$

[764] *Proof of (13.97.18):* Let $j\in\mathbb{N}$. We can represent the endomorphism f of V as an $n\times n$-matrix $F\in\mathbb{K}^{n\times n}$ for $n=\dim V$. This $n\times n$-matrix F is nilpotent (since f is nilpotent) and has Jordan type λ (since f has Jordan type λ). But Exercise 2.9.22(a) (applied to $N=F$) shows that F has Jordan type λ if and only if every $k\in\mathbb{N}$ satisfies $\dim\left(\ker\left(F^{k}\right)\right)=\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{k}$. Since we know that F has Jordan type λ, we thus conclude that every $k\in\mathbb{N}$ satisfies $\dim\left(\ker\left(F^{k}\right)\right)=\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{k}$. Applied to $k=j$, this yields $\dim\left(\ker\left(F^{j}\right)\right)=\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{j}$.

Since the matrix F represents the endomorphism f, we have

$$\dim\left(\ker\left(F^{j}\right)\right)=\dim\left(\underbrace{\ker\left(f^{j}\right)}_{=\left(f^{j}\right)^{-1}(0)}\right)=\dim\left(\left(f^{j}\right)^{-1}(0)\right).$$

Compared with $\dim\left(\ker\left(F^{j}\right)\right)=\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{j}$, this yields

$$\dim\left(\left(f^{j}\right)^{-1}(0)\right)=\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{j},$$

and thus (13.97.18) is proven.

[765] *Proof of (13.97.19):* Let $j\in\{1,2,3,\ldots\}$. Then,

$$\begin{aligned}
&\underbrace{\dim\left(\left(f^{j}\right)^{-1}(0)\right)}_{\substack{=\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{j}\\ \text{(by (13.97.18))}}}-\underbrace{\dim\left(\left(f^{j-1}\right)^{-1}(0)\right)}_{\substack{=\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{j-1}\\ \text{(by (13.97.18), applied}\\ \text{to } j-1 \text{ instead of } j)}}\\
&=\left(\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{j}\right)-\left(\left(\lambda^{t}\right)_{1}+\left(\lambda^{t}\right)_{2}+\cdots+\left(\lambda^{t}\right)_{j-1}\right)=\left(\lambda^{t}\right)_{j},
\end{aligned}$$

so that (13.97.19) is proven.

Adding this equality to the equality

$$\begin{aligned}\left(\mu^t\right)_j &= \underbrace{a_{0,j}}_{\substack{=\dim\left(\left(f^0\right)^{-1}(U)\cap\ker\left(f^j\right)\right)\\ \text{(by the definition of } a_{0,j}\text{)}}} - \underbrace{a_{0,j-1}}_{\substack{=\dim\left(\left(f^0\right)^{-1}(U)\cap\ker\left(f^{j-1}\right)\right)\\ \text{(by the definition of } a_{0,j-1}\text{)}}} \qquad \text{(by (13.97.11))}\\ &= \dim\left(\left(\underbrace{f^0}_{=\mathrm{id}}\right)^{-1}(U)\cap\ker\left(f^j\right)\right) - \dim\left(\left(\underbrace{f^0}_{=\mathrm{id}}\right)^{-1}(U)\cap\ker\left(f^{j-1}\right)\right)\\ &= \dim\left(\underbrace{(\mathrm{id})^{-1}(U)}_{=U}\cap\underbrace{\ker\left(f^j\right)}_{=\left(f^j\right)^{-1}(0)}\right) - \dim\left(\underbrace{(\mathrm{id})^{-1}(U)}_{=U}\cap\underbrace{\ker\left(f^{j-1}\right)}_{=\left(f^{j-1}\right)^{-1}(0)}\right)\\ &= \dim\left(U\cap\left(f^j\right)^{-1}(0)\right) - \dim\left(U\cap\left(f^{j-1}\right)^{-1}(0)\right),\end{aligned}$$

we obtain $\gamma_j = \left(\lambda^t\right)_j$ for every $j \in \{1,2,3,\ldots\}$. Thus, $\gamma = \lambda^t$. Hence, T is a column-strict tableau of shape λ^t/μ^t (since T is a column-strict tableau of shape γ/μ^t).

Next, let us prove that $\operatorname{cont} T = \nu^t$. Indeed, we first notice that

$$\dim\left(\left(f^i\right)^{-1}(U)\right) = (\dim U) + \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_i \qquad \text{for every } i \in \mathbb{N}. \tag{13.97.20}$$

[766] As a consequence of this, we have

$$\dim\left(\left(f^i\right)^{-1}(U)\right) - \dim\left(\left(f^{i-1}\right)^{-1}(U)\right) = \left(\nu^t\right)_i \qquad \text{for every } i \in \{1,2,3,\ldots\}. \tag{13.97.21}$$

[767]

[766] *Proof of (13.97.20):* Let $i \in \mathbb{N}$. Recall that the nilpotent endomorphism $\overline{f}$ of the quotient space V/U (induced by $f \in \operatorname{End} V$) has Jordan type ν. We can represent this nilpotent endomorphism $\overline{f}$ of V/U as an $\ell\times\ell$-matrix $H \in \mathbb{K}^{\ell\times\ell}$ for $\ell = \dim(V/U)$. This $\ell\times\ell$-matrix H is nilpotent (since $\overline{f}$ is nilpotent) and has Jordan type ν (since $\overline{f}$ has Jordan type ν). But Exercise 2.9.22(a) (applied to ℓ, H and ν instead of n, N and λ) shows that H has Jordan type ν if and only if every $k \in \mathbb{N}$ satisfies $\dim\left(\ker\left(H^k\right)\right) = \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_k$. Since we know that H has Jordan type ν, we thus conclude that every $k \in \mathbb{N}$ satisfies $\dim\left(\ker\left(H^k\right)\right) = \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_k$. Applied to $k = i$, this yields $\dim\left(\ker\left(H^i\right)\right) = \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_i$.

Since the matrix H represents the endomorphism $\overline{f}$, we have

$$\dim\left(\ker\left(\overline{f}^i\right)\right) = \dim\left(\ker\left(H^i\right)\right) = \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_i.$$

But $\left(f^i\right)^{-1}(U)$ is a $\mathbb{K}$-vector subspace of V containing U. Thus, $\left(f^i\right)^{-1}(U)/U$ is canonically a $\mathbb{K}$-vector subspace of V/U. Moreover, this subspace $\left(f^i\right)^{-1}(U)/U$ is precisely the kernel $\ker\left(\overline{f}^i\right)$ (this is straightforward to check). Hence,

$$\dim\left(\left(f^i\right)^{-1}(U)/U\right) = \dim\left(\ker\left(\overline{f}^i\right)\right) = \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_i.$$

Since

$$\dim\left(\left(f^i\right)^{-1}(U)/U\right) = \dim\left(\left(f^i\right)^{-1}(U)\right) - \dim U,$$

this rewrites as

$$\dim\left(\left(f^i\right)^{-1}(U)\right) - \dim U = \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_i.$$

Adding $\dim U$ to both sides of this equality yields (13.97.20).

[767] *Proof of (13.97.21):* Let $i \in \{1,2,3,\ldots\}$. Then,

$$\begin{aligned}&\underbrace{\dim\left(\left(f^i\right)^{-1}(U)\right)}_{\substack{=(\dim U)+\left(\nu^t\right)_1+\left(\nu^t\right)_2+\cdots+\left(\nu^t\right)_i\\ \text{(by (13.97.20))}}} - \underbrace{\dim\left(\left(f^{i-1}\right)^{-1}(U)\right)}_{\substack{=(\dim U)+\left(\nu^t\right)_1+\left(\nu^t\right)_2+\cdots+\left(\nu^t\right)_{i-1}\\ \text{(by (13.97.20), applied}\\ \text{to } i-1 \text{ instead of } i)}}\\ &= \left((\dim U) + \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_i\right) - \left((\dim U) + \left(\nu^t\right)_1 + \left(\nu^t\right)_2 + \cdots + \left(\nu^t\right)_{i-1}\right) = \left(\nu^t\right)_i.\end{aligned}$$

Thus, (13.97.21) is proven.

Now, for every $i \in \{1, 2, 3, \ldots\}$, we have

$$\begin{aligned}
(\operatorname{cont} T)_i &= \left|T^{-1}(i)\right| = (\text{the number of entries } i \text{ in } T) \\
&= \sum_{j=1}^{\infty} \underbrace{(\text{the number of all entries } i \text{ in the } j\text{-th row of } T)}_{\substack{=b_{i,j} \\ (\text{by (13.97.16)})}} = \sum_{j=1}^{\infty} \underbrace{b_{i,j}}_{=a_{i,j}-a_{i,j-1}-a_{i-1,j}+a_{i-1,j-1}} \\
&= \sum_{j=1}^{\infty} \underbrace{(a_{i,j}-a_{i,j-1}-a_{i-1,j}+a_{i-1,j-1})}_{=(a_{i,j}-a_{i,j-1})-(a_{i-1,j}-a_{i-1,j-1})} = \sum_{j=1}^{\infty} \left((a_{i,j}-a_{i,j-1})-(a_{i-1,j}-a_{i-1,j-1})\right) \\
&= \underbrace{\sum_{j=1}^{\infty} (a_{i,j}-a_{i,j-1})}_{\substack{=\dim\left(\left(f^i\right)^{-1}(U)\right)-\dim\left(\left(f^i\right)^{-1}(U)\cap 0\right) \\ (\text{by Lemma 13.97.1(g), applied to} \\ W=V,\ A=U,\ B=0 \text{ and } w_{i,j}=a_{i,j})}} - \underbrace{\sum_{j=1}^{\infty} (a_{i-1,j}-a_{i-1,j-1})}_{\substack{=\dim\left(\left(f^{i-1}\right)^{-1}(U)\right)-\dim\left(\left(f^{i-1}\right)^{-1}(U)\cap 0\right) \\ (\text{by Lemma 13.97.1(f), applied to} \\ V,\ U,\ 0,\ a_{i,j} \text{ and } i-1 \text{ instead of } W,\ A,\ B,\ w_{i,j} \text{ and } i)}} \\
&= \left(\dim\left(\left(f^i\right)^{-1}(U)\right) - \dim \underbrace{\left(\left(f^i\right)^{-1}(U)\cap 0\right)}_{=0}\right) - \left(\dim\left(\left(f^{i-1}\right)^{-1}(U)\right) - \dim \underbrace{\left(\left(f^{i-1}\right)^{-1}(U)\cap 0\right)}_{=0}\right) \\
&= \left(\dim\left(\left(f^i\right)^{-1}(U)\right) - \underbrace{\dim 0}_{=0}\right) - \left(\dim\left(\left(f^{i-1}\right)^{-1}(U)\right) - \underbrace{\dim 0}_{=0}\right) \\
&= \dim\left(\left(f^i\right)^{-1}(U)\right) - \dim\left(\left(f^{i-1}\right)^{-1}(U)\right) = \left(\nu^t\right)_i \qquad (\text{by (13.97.21)}).
\end{aligned}$$

Hence, $\operatorname{cont} T = \nu^t$.

We shall next see that for every positive integer j, the weak composition $\operatorname{cont}(T|_{\text{cols}\geq j})$ is a partition. Here, and in the following, we are using the notations of Exercise 2.9.18.

We first notice that every $i \in \{1, 2, 3, \ldots\}$ and $j \in \mathbb{N}$ satisfy

$$(\text{the number of entries } i \text{ in the first } j \text{ rows of } T) = a_{i,j} - a_{i-1,j}. \tag{13.97.22}$$

[768] Now, for every positive integers j and i, we have

$$\begin{aligned}
&(\text{the number of entries } i+1 \text{ in the first } j \text{ rows of } T) \\
&= a_{i+1,j} - a_{i,j} \qquad (\text{by (13.97.22), applied to } i+1 \text{ instead of } i) \\
&\leq a_{i,j-1} - a_{i-1,j-1} \qquad \left(\begin{array}{c}\text{by Lemma 13.97.1(c), applied to} \\ V,\ U,\ 0,\ a_{i,j} \text{ and } j-1 \text{ instead of } W,\ A,\ B,\ w_{i,j} \text{ and } j\end{array}\right) \\
&= (\text{the number of entries } i \text{ in the first } j-1 \text{ rows of } T)
\end{aligned}$$

(since (13.97.22) (applied to $j-1$ instead of j) yields (the number of entries i in the first $j-1$ rows of T) $= a_{i,j-1} - a_{i-1,j-1}$). In other words, for every positive integers j and i, the number of entries $i+1$ in the first j rows of T is $\leq$ to the number of entries i in the first $j-1$ rows of T. In other words, Assertion $\mathcal{D}$ of Exercise 2.9.18(b) (with λ and μ replaced by λ^t and μ^t) is satisfied. Hence, Assertion $\mathcal{C}$ of Exercise 2.9.18(b) (with λ and μ replaced by λ^t and μ^t) is satisfied as well (because Exercise 2.9.18(b) yields that these Assertions $\mathcal{C}$ and $\mathcal{D}$ are equivalent). In other words, for every positive integer j, the weak composition $\operatorname{cont}(T|_{\text{cols}\geq j})$ is a partition.

Now, let us forget that we defined ν and T. We thus have found a column-strict tableau T of shape λ^t/μ^t with $\operatorname{cont} T = \nu^t$ which has the property that for every positive integer j, the weak composition $\operatorname{cont}(T|_{\text{cols}\geq j})$ is a partition. But we know that the number of such tableaux is $c^{\lambda^t}_{\mu^t,\nu^t}$ (by Corollary 2.6.12, applied to λ^t, μ^t and ν^t instead of λ, μ and ν). Hence, this number $c^{\lambda^t}_{\mu^t,\nu^t}$ must be $\neq 0$ (because we have found such a tableau T). So we have proven that $c^{\lambda^t}_{\mu^t,\nu^t} \neq 0$. Now, Exercise 2.7.11(c) yields $c^{\lambda}_{\mu,\nu} = c^{\lambda^t}_{\mu^t,\nu^t} \neq 0$, so that Exercise 2.9.22(b) is solved.

13.98. **Solution to Exercise 2.9.24.** *Solution to Exercise 2.9.24.* Define a set $\mathfrak{D}$ by

$$\mathfrak{D} = \left\{ g \in \Lambda \mid g^{\perp} a = (\omega(g))^{\perp} a \right\}. \tag{13.98.1}$$

We shall show that $\mathfrak{D}$ is a $\mathbf{k}$-subalgebra of Λ.

Define a map $\kappa : \Lambda \to \Lambda$ by

$$\left(\kappa(g) = g^{\perp} a - (\omega(g))^{\perp} a \qquad \text{for every } g \in \Lambda \right).$$

[768] *Proof of (13.97.22):* Let $i \in \{1,2,3,\ldots\}$ and $j \in \mathbb{N}$. We have

$$\begin{aligned}
&(\text{the number of entries } i \text{ in the first } j \text{ rows of } T) \\
&= \sum_{k=1}^{j} \underbrace{(\text{the number of all entries } i \text{ in the } k\text{-th row of } T)}_{\substack{=b_{i,k} \\ (\text{since (13.97.16) (applied to } (i,k) \text{ instead of } (i,j)) \text{ yields} \\ b_{i,k}=(\text{the number of all entries } i \text{ in the } k\text{-th row of } T))}} \\
&= \sum_{k=1}^{j} \underbrace{b_{i,k}}_{\substack{=a_{i,k}-a_{i,k-1}-a_{i-1,k}+a_{i-1,k-1} \\ (\text{by the definition of } b_{i,k})}} = \sum_{k=1}^{j} \underbrace{\left(a_{i,k} - a_{i,k-1} - a_{i-1,k} + a_{i-1,k-1}\right)}_{=(a_{i,k}-a_{i-1,k})-(a_{i,k-1}-a_{i-1,k-1})} \\
&= \sum_{k=1}^{j} \left(\left(a_{i,k} - a_{i-1,k}\right) - \left(a_{i,k-1} - a_{i-1,k-1}\right) \right) \\
&= \left(a_{i,j} - a_{i-1,j}\right) - \left(\underbrace{a_{i,0}}_{\substack{=0 \\ (\text{by (13.97.9)})}} - \underbrace{a_{i-1,0}}_{\substack{=0 \\ (\text{by (13.97.9), applied} \\ \text{to } i-1 \text{ instead of } i)}} \right) \qquad (\text{by the telescope principle}) \\
&= \left(a_{i,j} - a_{i-1,j}\right) - (0-0) = a_{i,j} - a_{i-1,j}.
\end{aligned}$$

This proves (13.97.22).

This map κ is $\mathbf{k}$-linear[769]. Hence, its kernel $\ker\kappa$ is a $\mathbf{k}$-submodule of Λ. Since

$$\ker\kappa = \left\{ g \in \Lambda \mid \underbrace{\kappa(g)}_{\substack{=g^\perp a - (\omega(g))^\perp a \\ \text{(by the definition of } \kappa)}} = 0 \right\} = \left\{ g \in \Lambda \mid \underbrace{g^\perp a - (\omega(g))^\perp a = 0}_{\iff \left(g^\perp a = (\omega(g))^\perp a\right)} \right\}$$
$$= \left\{ g \in \Lambda \mid g^\perp a = (\omega(g))^\perp a \right\} = \mathfrak{D} \qquad \text{(by (13.98.1))},$$

this rewrites as follows: The set $\mathfrak{D}$ is a $\mathbf{k}$-submodule of Λ.

Furthermore, we have the following two observations:

- We have $1 \in \mathfrak{D}$ [770].
- We have $xy \in \mathfrak{D}$ for each $x \in \mathfrak{D}$ and $y \in \mathfrak{D}$ [771].

[769] *Proof.* For each $g \in \Lambda$, we have $g^\perp a = \sum (g, a_1) a_2$ (by the definition of $g^\perp$). Hence, the element $g^\perp a$ of Λ depends $\mathbf{k}$-linearly on g (because the Hall inner product $(\cdot,\cdot)$ is $\mathbf{k}$-bilinear). Thus, the element $(\omega(g))^\perp a$ also depends $\mathbf{k}$-linearly on g (since the map ω is $\mathbf{k}$-linear). Hence, the difference $g^\perp a - (\omega(g))^\perp a$ of these two elements also depends $\mathbf{k}$-linearly on g. In other words, $\kappa(g)$ depends $\mathbf{k}$-linearly on g (since $\kappa(g) = g^\perp a - (\omega(g))^\perp a$). In other words, the map κ is $\mathbf{k}$-linear.

[770] *Proof.* Recall that ω is a $\mathbf{k}$-algebra endomorphism of Λ. Hence, $\omega(1) = 1$. Thus, $\left(\underbrace{\omega(1)}_{=1}\right)^\perp a = 1^\perp a$, so that $1^\perp a = (\omega(1))^\perp a$. Hence, 1 is an element of Λ and satisfies $1^\perp a = (\omega(1))^\perp a$. Thus,

$$1 \in \left\{ g \in \Lambda \mid g^\perp a = (\omega(g))^\perp a \right\} = \mathfrak{D} \qquad \text{(by (13.98.1))},$$

qed.

[771] *Proof.* Let $x \in \mathfrak{D}$ and $y \in \mathfrak{D}$.

We have $x \in \mathfrak{D} = \left\{ g \in \Lambda \mid g^\perp a = (\omega(g))^\perp a \right\}$. In other words, x is an element of Λ and satisfies $x^\perp a = (\omega(x))^\perp a$.

We have $y \in \mathfrak{D} = \left\{ g \in \Lambda \mid g^\perp a = (\omega(g))^\perp a \right\}$. In other words, y is an element of Λ and satisfies $y^\perp a = (\omega(y))^\perp a$.

Proposition 2.8.2(ii) (applied to $f = \omega(y)$ and $g = \omega(x)$) yields

$$(\omega(y)\,\omega(x))^\perp a = (\omega(x))^\perp \left((\omega(y))^\perp a\right). \tag{13.98.2}$$

But $\omega(xy) = \omega(x)\,\omega(y)$ (since ω is an endomorphism of the $\mathbf{k}$-algebra Λ). Hence,

$$\Bigg(\underbrace{\omega(xy)}_{\substack{=\omega(x)\omega(y) \\ =\omega(y)\omega(x)}}\Bigg)^\perp a = (\omega(y)\,\omega(x))^\perp a = (\omega(x))^\perp \left((\omega(y))^\perp a\right) \tag{13.98.3}$$

(by (13.98.2)).

On the other hand, Proposition 2.8.2(ii) (applied to $f = x$ and $g = y$) yields

$$(xy)^\perp a = y^\perp \Bigg(\underbrace{x^\perp a}_{=(\omega(x))^\perp a}\Bigg) = y^\perp \left((\omega(x))^\perp a\right).$$

Comparing this with

$$(\omega(x)\,y)^\perp a = y^\perp \left((\omega(x))^\perp a\right) \qquad \text{(by Proposition 2.8.2(ii) (applied to } f = \omega(x) \text{ and } g = y)),$$

we obtain

$$(xy)^\perp a = \Bigg(\underbrace{\omega(x)\,y}_{=y\omega(x)}\Bigg)^\perp a = (y\omega(x))^\perp a = (\omega(x))^\perp \Bigg(\underbrace{y^\perp a}_{=(\omega(y))^\perp a}\Bigg)$$
$$\text{(by Proposition 2.8.2(ii) (applied to } f = y \text{ and } g = \omega(x)\,))$$
$$= (\omega(x))^\perp \left((\omega(y))^\perp a\right) = (\omega(xy))^\perp a \qquad \text{(by (13.98.3))}.$$

Thus, xy is an element of Λ and satisfies $(xy)^\perp a = (\omega(xy))^\perp a$. Hence,

$$xy \in \left\{ g \in \Lambda \mid g^\perp a = (\omega(g))^\perp a \right\} = \mathfrak{D} \qquad \text{(by (13.98.1))},$$

qed.

Combining these two observations, we conclude that the set $\mathfrak{D}$ is a $\mathbf{k}$-subalgebra of Λ (since we already know that $\mathfrak{D}$ is a $\mathbf{k}$-submodule of Λ). In view of (13.98.1), this rewrites as follows: The set $\left\{g \in \Lambda \ \mid \ g^{\perp} a = (\omega(g))^{\perp} a\right\}$ is a $\mathbf{k}$-subalgebra of Λ. This solves Exercise 2.9.24(a).

(b) We have

$$e_k^{\perp} a = h_k^{\perp} a \qquad \text{for each positive integer } k \tag{13.98.4}$$

(by assumption). Thus,

$$e_n \in \mathfrak{D} \text{ for each } n \in \{1, 2, 3, \ldots\} \tag{13.98.5}$$

[772].

But Proposition 2.4.1 shows that the family $(e_n)_{n \in \{1,2,3,\ldots\}}$ generates Λ as a $\mathbf{k}$-algebra. Thus, the smallest $\mathbf{k}$-subalgebra of Λ that contains all elements of the family $(e_n)_{n \in \{1,2,3,\ldots\}}$ is Λ itself. In other words, if $\mathfrak{B}$ is a $\mathbf{k}$-subalgebra of Λ satisfying

$$(e_n \in \mathfrak{B} \text{ for each } n \in \{1, 2, 3, \ldots\}),$$

then $\mathfrak{B} = \Lambda$. Applying this to $\mathfrak{B} = \mathfrak{D}$, we conclude that $\mathfrak{D} = \Lambda$ (because $\mathfrak{D}$ is a $\mathbf{k}$-subalgebra of Λ, and because it satisfies (13.98.5)).

Now, let $f \in \Lambda$. Then, $f \in \Lambda = \mathfrak{D} = \left\{g \in \Lambda \ \mid \ g^{\perp} a = (\omega(g))^{\perp} a\right\}$ (by (13.98.1)). In other words, f is an element of Λ and satisfies $f^{\perp} a = (\omega(f))^{\perp} a$.

Now, forget that we fixed f. We thus have proven that $f^{\perp} a = (\omega(f))^{\perp} a$ for each $f \in \Lambda$. Renaming f as g in this statement, we conclude the following: $g^{\perp} a = (\omega(g))^{\perp} a$ for each $g \in \Lambda$. This solves Exercise 2.9.24(b).

13.99. **Solution to Exercise 2.9.25.** *Solution to Exercise 2.9.25.* Let us begin by proving a few simple lemmas:

Lemma 13.99.1. *Let $n \in \mathbb{N}$. Let ρ be the partition $(n-1, n-2, \ldots, 1)$. Let $\mu \in \operatorname{Par}$. Then, ρ/μ is a horizontal strip if and only if ρ/μ is a vertical strip.*

Lemma 13.99.1 becomes visually obvious if one draws in one's mind the Ferrers diagram of the staircase partition ρ and attempts to cut off either a horizontal strip or a vertical strip from it (in either case, the only possibilities are to remove some of its corners). But let us give a rigorous proof:

Proof of Lemma 13.99.1. Write the partition μ in the form $\mu = (\mu_1, \mu_2, \mu_3, \ldots)$. Write the partition ρ in the form $\rho = (\rho_1, \rho_2, \rho_3, \ldots)$. Then,

$$(\rho_1, \rho_2, \rho_3, \ldots) = \rho = (n-1, n-2, \ldots, 1) = (n-1, n-2, \ldots, 1, 0, 0, 0, \ldots).$$

Hence,

$$\rho_i = \begin{cases} n - i, & \text{if } i < n; \\ 0, & \text{if } i \geq n \end{cases} \qquad \text{for each positive integer } i. \tag{13.99.1}$$

Now, we are going to prove the following two claims:

Claim 1: If ρ/μ is a horizontal strip, then ρ/μ is a vertical strip.

Claim 2: If ρ/μ is a vertical strip, then ρ/μ is a horizontal strip.

[772] *Proof of (13.98.5):* Let $n \in \{1, 2, 3, \ldots\}$. Thus, n is a positive integer. Hence, $\omega(e_n) = h_n$ (by the definition of ω). Thus, $\Bigg(\underbrace{\omega(e_n)}_{=h_n}\Bigg)^{\perp} a = h_n^{\perp} a$. But (13.98.4) (applied to $k = n$) yields $e_n^{\perp} a = h_n^{\perp} a$. Comparing this with $(\omega(e_n))^{\perp} a = h_n^{\perp} a$, we find $e_n^{\perp} a = (\omega(e_n))^{\perp} a$. Hence, e_n is an element of Λ and satisfies $e_n^{\perp} a = (\omega(e_n))^{\perp} a$. Therefore,

$$e_n \in \left\{g \in \Lambda \ \mid \ g^{\perp} a = (\omega(g))^{\perp} a\right\} = \mathfrak{D} \qquad \text{(by (13.98.1))},$$

qed.

Proof of Claim 1: Assume that ρ/μ is a horizontal strip. We must then prove that ρ/μ is a vertical strip.

We have $\mu \subseteq \rho$ (since ρ/μ is a horizontal strip). Exercise 2.7.5(a) (applied to $\lambda = \rho$ and $\lambda_i = \rho_i$) yields that ρ/μ is a horizontal strip if and only if every $i \in \{1, 2, 3, \ldots\}$ satisfies $\mu_i \geq \rho_{i+1}$. Thus,

$$\text{every } i \in \{1, 2, 3, \ldots\} \text{ satisfies } \mu_i \geq \rho_{i+1} \tag{13.99.2}$$

(since ρ/μ is a horizontal strip).

Now, every $i \in \{1, 2, 3, \ldots\}$ satisfies $\rho_i \leq \mu_i + 1$ [773]. But Exercise 2.7.5(b) (applied to $\lambda = \rho$ and $\lambda_i = \rho_i$) yields that ρ/μ is a vertical strip if and only if every $i \in \{1, 2, 3, \ldots\}$ satisfies $\rho_i \leq \mu_i + 1$. Thus, ρ/μ is a vertical strip (since every $i \in \{1, 2, 3, \ldots\}$ satisfies $\rho_i \leq \mu_i + 1$). This proves Claim 1.

Proof of Claim 2: Assume that ρ/μ is a vertical strip. We must then prove that ρ/μ is a horizontal strip.

We know that ρ/μ is a vertical strip. In particular, $\mu \subseteq \rho$.

Exercise 2.7.5(b) (applied to $\lambda = \rho$ and $\lambda_i = \rho_i$) yields that ρ/μ is a vertical strip if and only if every $i \in \{1, 2, 3, \ldots\}$ satisfies $\rho_i \leq \mu_i + 1$. Thus,

$$\text{every } i \in \{1, 2, 3, \ldots\} \text{ satisfies } \rho_i \leq \mu_i + 1 \tag{13.99.3}$$

(since ρ/μ is a vertical strip).

Now, every $i \in \{1, 2, 3, \ldots\}$ satisfies $\mu_i \geq \rho_{i+1}$ [774]. But Exercise 2.7.5(a) (applied to $\lambda = \rho$ and $\lambda_i = \rho_i$) yields that ρ/μ is a horizontal strip if and only if every $i \in \{1, 2, 3, \ldots\}$ satisfies $\mu_i \geq \rho_{i+1}$. Thus, ρ/μ is a horizontal strip (since every $i \in \{1, 2, 3, \ldots\}$ satisfies $\mu_i \geq \rho_{i+1}$). This proves Claim 2.

[773] *Proof.* Let $i \in \{1, 2, 3, \ldots\}$. We must show that $\rho_i \leq \mu_i + 1$.

If $i \geq n - 1$, then

$$\begin{aligned} \rho_i &= \begin{cases} n - i, & \text{if } i < n; \\ 0, & \text{if } i \geq n \end{cases} \qquad \text{(by (13.99.1))} \\ &\leq \begin{cases} 1, & \text{if } i < n; \\ 0, & \text{if } i \geq n \end{cases} \qquad \text{(since } n - i \leq 1 \text{ (because } i \geq n - 1)) \\ &\leq \begin{cases} 1, & \text{if } i < n; \\ 1, & \text{if } i \geq n \end{cases} \qquad \text{(since } 0 \leq 1) \\ &= 1 = \underbrace{0}_{\leq \mu_i} + 1 \leq \mu_i + 1. \end{aligned}$$

Hence, if $i \geq n - 1$, then $\rho_i \leq \mu_i + 1$ holds. Thus, for the rest of this proof of $\rho_i \leq \mu_i + 1$, we WLOG assume that we don't have $i \geq n - 1$.

We have $i < n - 1$ (since we don't have $i \geq n - 1$). But (13.99.1) yields $\rho_i = \begin{cases} n - i, & \text{if } i < n; \\ 0, & \text{if } i \geq n \end{cases} = n - i$ (since $i < n - 1 < n$).

But from $i < n - 1$, we obtain $i + 1 < n$. Now, (13.99.1) (applied to $i + 1$ instead of i) yields $\rho_{i+1} = \begin{cases} n - (i + 1), & \text{if } i + 1 < n; \\ 0, & \text{if } i + 1 \geq n \end{cases} = n - (i + 1)$ (since $i + 1 < n$).

But (13.99.2) yields $\mu_i \geq \rho_{i+1} = n - (i + 1) = n - i - 1$. Adding 1 to both sides of this inequality, we obtain $\mu_i + 1 \geq n - i = \rho_i$ (since $\rho_i = n - i$). Hence, $\rho_i \leq \mu_i + 1$. This completes our proof of $\rho_i \leq \mu_i + 1$.

[774] *Proof.* Let $i \in \{1, 2, 3, \ldots\}$. We must show that $\mu_i \geq \rho_{i+1}$.

Applying (13.99.1) to $i + 1$ instead of i, we obtain $\rho_{i+1} = \begin{cases} n - (i + 1), & \text{if } i + 1 < n; \\ 0, & \text{if } i + 1 \geq n \end{cases}$.

If $i + 1 \geq n$, then

$$\begin{aligned} \rho_{i+1} &= \begin{cases} n - (i + 1), & \text{if } i + 1 < n; \\ 0, & \text{if } i + 1 \geq n \end{cases} = 0 \qquad \text{(since } i + 1 \geq n) \\ &\leq \mu_i. \end{aligned}$$

In other words, if $i + 1 \geq n$, then $\mu_i \geq \rho_{i+1}$. Thus, for the rest of this proof of $\mu_i \geq \rho_{i+1}$, we WLOG assume that we don't have $i + 1 \geq n$.

We have $i + 1 < n$ (since we don't have $i + 1 \geq n$). Thus, $\rho_{i+1} = \begin{cases} n - (i + 1), & \text{if } i + 1 < n; \\ 0, & \text{if } i + 1 \geq n \end{cases} = n - (i + 1)$ (since $i + 1 < n$).

But (13.99.1) yields $\rho_i = \begin{cases} n - i, & \text{if } i < n; \\ 0, & \text{if } i \geq n \end{cases} = n - i$ (since $i < i + 1 < n$).

From (13.99.3), we obtain $\rho_i \leq \mu_i + 1$, so that $\mu_i + 1 \geq \rho_i = n - i$. Subtracting 1 from both sides of this inequality, we find $\mu_i \geq n - i - 1 = n - (i + 1) = \rho_{i+1}$ (since $\rho_{i+1} = n - (i + 1)$). This completes our proof of $\mu_i \geq \rho_{i+1}$.

Combining Claim 1 with Claim 2, we conclude that ρ/μ is a horizontal strip if and only if ρ/μ is a vertical strip. Lemma 13.99.1 is thus proven. □

Lemma 13.99.2. *Let $n \in \mathbb{N}$. Let ρ be the partition $(n-1, n-2, \ldots, 1)$. Let k be a positive integer. Then, $e_k^\perp s_\rho = h_k^\perp s_\rho$.*

Proof of Lemma 13.99.2. Fix $\nu \in \operatorname{Par}$. We have the following logical equivalence:

$$\begin{aligned} & (\rho/\nu \text{ is a horizontal } k\text{-strip}) \\ \iff & (\rho/\nu \text{ is a horizontal strip and has size } k) \\ & \qquad (\text{by the definition of a "horizontal } k\text{-strip"}) \\ \iff & (\rho/\nu \text{ is a horizontal strip and satisfies } |\rho/\nu| = k) . \end{aligned} \tag{13.99.4}$$

Similarly, we also have the following logical equivalence:

$$\begin{aligned} & (\rho/\nu \text{ is a vertical } k\text{-strip}) \\ \iff & (\rho/\nu \text{ is a vertical strip and satisfies } |\rho/\nu| = k) . \end{aligned} \tag{13.99.5}$$

But Lemma 13.99.1 (applied to $\mu = \nu$) shows that ρ/ν is a horizontal strip if and only if ρ/ν is a vertical strip. In other words, we have the following logical equivalence:

$$(\rho/\nu \text{ is a horizontal strip}) \iff (\rho/\nu \text{ is a vertical strip}) . \tag{13.99.6}$$

Now, we have the following chain of logical equivalences:

$$\begin{aligned} & (\rho/\nu \text{ is a horizontal } k\text{-strip}) \\ \iff & \left(\underbrace{\rho/\nu \text{ is a horizontal strip}}_{\substack{\iff (\rho/\nu \text{ is a vertical strip}) \\ (\text{by (13.99.6)})}} \text{ and satisfies } |\rho/\nu| = k \right) \qquad (\text{by (13.99.4)}) \\ \iff & (\rho/\nu \text{ is a vertical strip and satisfies } |\rho/\nu| = k) \\ \iff & (\rho/\nu \text{ is a vertical } k\text{-strip}) \qquad (\text{by (13.99.5)}) . \end{aligned} \tag{13.99.7}$$

Now, forget that we fixed ν. We thus have proven the equivalence (13.99.7) for each $\nu \in \operatorname{Par}$.

Lemma 13.77.2(a) (applied to $\gamma = \rho$) yields

$$h_k^\perp s_\rho = \underbrace{\sum_{\substack{\nu \in \operatorname{Par}; \\ \rho/\nu \text{ is a} \\ \text{horizontal } k\text{-strip}}}}_{\substack{= \sum_{\substack{\nu \in \operatorname{Par}; \\ \rho/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} \\ (\text{by the equivalence (13.99.7)})}} s_\nu = \sum_{\substack{\nu \in \operatorname{Par}; \\ \rho/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu .$$

Comparing this with

$$e_k^\perp s_\rho = \sum_{\substack{\nu \in \operatorname{Par}; \\ \rho/\nu \text{ is a} \\ \text{vertical } k\text{-strip}}} s_\nu \qquad (\text{by Lemma 13.77.2(b) (applied to } \gamma = \rho)) ,$$

we obtain $e_k^\perp s_\rho = h_k^\perp s_\rho$. This proves Lemma 13.99.2. □

Lemma 13.99.3. *Let $\lambda \in \operatorname{Par}$. Then, $\omega(s_\lambda) = s_{\lambda^t}$.*

Proof of Lemma 13.99.3. We have $\varnothing \subseteq \lambda$. Hence, the first equation of (2.4.15) (applied to $\mu = \varnothing$) yields $\omega\left(s_{\lambda/\varnothing}\right) = s_{\lambda^t/\varnothing^t} = s_{\lambda^t/\varnothing}$ (since $\varnothing^t = \varnothing$).

But recall that $s_\lambda = s_{\lambda/\varnothing}$. The same argument (but applied to λ^t instead of λ) shows that $s_{\lambda^t} = s_{\lambda^t/\varnothing}$. Comparing this with $\omega\left(\underbrace{s_\lambda}_{=s_{\lambda/\varnothing}}\right) = \omega\left(s_{\lambda/\varnothing}\right) = s_{\lambda^t/\varnothing}$, we obtain $\omega\left(s_\lambda\right) = s_{\lambda^t}$. This proves Lemma 13.99.3.

□

We can now solve Exercise 2.9.25 easily:

Solution to Exercise 2.9.25. Lemma 13.99.2 shows that $e_k^\perp s_\rho = h_k^\perp s_\rho$ for each positive integer k. Hence, Exercise 2.9.24(b) (applied to $a = s_\rho$) yields that

$$g^\perp s_\rho = \left(\omega\left(g\right)\right)^\perp s_\rho \qquad \text{for each } g \in \Lambda. \tag{13.99.8}$$

Recall that

$$s_\mu^\perp\left(s_\lambda\right) = s_{\lambda/\mu} \qquad \text{for every } \lambda \in \operatorname{Par} \text{ and } \mu \in \operatorname{Par}. \tag{13.99.9}$$

Fix $\mu \in \operatorname{Par}$. Then, Lemma 13.99.3 (applied to μ instead of λ) shows that $\omega\left(s_\mu\right) = s_{\mu^t}$. Now, (13.99.8) (applied to $g = s_\mu$) yields

$$s_\mu^\perp s_\rho = \left(\underbrace{\omega\left(s_\mu\right)}_{=s_{\mu^t}}\right)^\perp s_\rho = \left(s_{\mu^t}\right)^\perp s_\rho = \left(s_{\mu^t}\right)^\perp\left(s_\rho\right) = s_{\rho/\mu^t}$$

(by (13.99.9) (applied to ρ and μ^t instead of λ and μ)). Comparing this with

$$s_\mu^\perp s_\rho = s_\mu^\perp\left(s_\rho\right) = s_{\rho/\mu} \qquad \text{(by (13.99.9) (applied to } \lambda = \rho\text{))},$$

this yields $s_{\rho/\mu} = s_{\rho/\mu^t}$. This solves Exercise 2.9.25.

13.100. **Solution to Exercise 3.1.6.** *Solution to Exercise 3.1.6.* Let A be as in Proposition 3.1.2, and assume that $\mathbf{k} = \mathbb{Q}$. We have $\mathfrak{p} \cap I^2 = 0$ (by Proposition 3.1.2 (b)). Thus, Lemma 3.1.4 yields that A is commutative. Since A is self-dual, this yields that A is cocommutative. Hence, Exercise 1.5.14 (d) shows that the $\mathbf{k}$-algebra A is generated by the $\mathbf{k}$-submodule $\mathfrak{p}$. In other words, A is the $\mathbf{k}$-subalgebra of A generated by the $\mathbf{k}$-submodule $\mathfrak{p}$. Since the $\mathbf{k}$-subalgebra of A generated by the $\mathbf{k}$-submodule $\mathfrak{p}$ is $\sum_{n\geq 0}\mathfrak{p}^n$ (this is because generally, if B is a $\mathbf{k}$-algebra, and U is a $\mathbf{k}$-submodule of B, then the $\mathbf{k}$-subalgebra of B generated by the $\mathbf{k}$-submodule U is $\sum_{n\geq 0} U^n$), this rewrites as follows: A is $\sum_{n\geq 0}\mathfrak{p}^n$. Hence,

$$\begin{aligned}
A &= \sum_{n\geq 0}\mathfrak{p}^n = \underbrace{\mathfrak{p}^0}_{=\mathbf{k}\cdot 1_A} + \underbrace{\mathfrak{p}^1}_{=\mathfrak{p}} + \sum_{n\geq 2}\underbrace{\mathfrak{p}^n}_{=\mathfrak{p}\cdot\mathfrak{p}\cdot\mathfrak{p}^{n-2}} = \mathbf{k}\cdot 1_A + \mathfrak{p} + \sum_{n\geq 2}\underbrace{\mathfrak{p}}_{\subset I}\cdot\underbrace{\mathfrak{p}}_{\subset I}\cdot\mathfrak{p}^{n-2} \\
&\subset \mathbf{k}\cdot 1_A + \mathfrak{p} + \sum_{n\geq 2} I \cdot \underbrace{I\cdot\mathfrak{p}^{n-2}}_{\substack{\subset I \\ \text{(since } I \text{ is an ideal of } A\text{)}}} \subset \mathbf{k}\cdot 1_A + \mathfrak{p} + \underbrace{\sum_{n\geq 2} I\cdot I}_{\subset I\cdot I = I^2} \subset \mathbf{k}\cdot 1_A + \mathfrak{p} + I^2.
\end{aligned}$$

Now, let $a \in I$. Then, $\epsilon\left(a\right) = 0$ (by the definition of I). But we know that $a \in I \subset A \subset \mathbf{k}\cdot 1_A + \mathfrak{p} + I^2$. Hence, there exist some $\lambda \in \mathbf{k}$ and some $a' \in \mathfrak{p} + I^2$ such that $a = \lambda\cdot 1_A + a'$. Since $a' \in \mathfrak{p} + I^2 \subset I$, we have $\epsilon\left(a'\right) = 0$. Now, $\epsilon\left(a\right) = 0$, so that

$$0 = \epsilon\left(\underbrace{a}_{=\lambda\cdot 1_A + a'}\right) = \epsilon\left(\lambda\cdot 1_A + a'\right) = \lambda\underbrace{\epsilon\left(1_A\right)}_{=1} + \underbrace{\epsilon\left(a'\right)}_{=0} = \lambda,$$

so that $\lambda = 0$ and thus $a = \underbrace{\lambda}_{=0}\cdot 1_A + a' = a' \in \mathfrak{p} + I^2$. We thus have shown that every $a \in I$ satisfies $a \in \mathfrak{p} + I^2$. Hence, $I \subset \mathfrak{p} + I^2$. Combined with $\mathfrak{p} + I^2 \subset I$, this yields $I = \mathfrak{p} + I^2$, and thus $I = \mathfrak{p} \oplus I^2$ (since $\mathfrak{p} \cap I^2 = 0$). This proves Proposition 3.1.2(c).

13.101. **Solution to Exercise 3.1.9.** *Solution to Exercise 3.1.9.* Corollary 2.5.17(a) yields that $(h_\lambda)_{\lambda \in \mathrm{Par}}$ and $(m_\lambda)_{\lambda \in \mathrm{Par}}$ are dual bases with respect to the Hall inner product on Λ. In other words,

$$(h_\lambda, m_\mu) = \delta_{\lambda,\mu} \qquad \text{for any partitions } \lambda \text{ and } \mu.$$

Thus, every nonempty partition λ satisfies $(h_\lambda, m_\varnothing) = \delta_{\lambda,\varnothing} = 0$. Hence, every nonempty partition λ satisfies

$$\left(h_\lambda, \underbrace{1}_{=m_\varnothing}\right) = (h_\lambda, m_\varnothing) = 0. \tag{13.101.1}$$

Recall the following fundamental fact from linear algebra: If $\mathbf{k}$ is a commutative ring, if A is a $\mathbf{k}$-module, if $(\cdot,\cdot) : A \times A \to \mathbf{k}$ is a symmetric $\mathbf{k}$-bilinear form on A, and if $(u_\lambda)_{\lambda \in L}$ and $(v_\lambda)_{\lambda \in L}$ are two $\mathbf{k}$-bases of A which are dual to each other with respect to the form $(\cdot,\cdot)$ (where L is some indexing set), then every $a \in A$ satisfies

$$a = \sum_{\lambda \in L} (u_\lambda, a)\, v_\lambda. \tag{13.101.2}$$

We can apply this fact to $A = \Lambda$, $L = \mathrm{Par}$, $(u_\lambda)_{\lambda \in L} = (h_\lambda)_{\lambda \in \mathrm{Par}}$ and $(v_\lambda)_{\lambda \in L} = (m_\lambda)_{\lambda \in \mathrm{Par}}$ (since the bases $(h_\lambda)_{\lambda \in \mathrm{Par}}$ and $(m_\lambda)_{\lambda \in \mathrm{Par}}$ of Λ are dual to each other with respect to the Hall inner product $(\cdot,\cdot)$). As a result, we obtain that every $a \in \Lambda$ satisfies

$$a = \sum_{\lambda \in \mathrm{Par}} (h_\lambda, a)\, m_\lambda. \tag{13.101.3}$$

Now, let us solve the exercise. We need to show that for every $a \in \Lambda$, the element a of Λ is primitive if and only if a lies in the $\mathbf{k}$-linear span of $p_1, p_2, p_3, \ldots$. The "if" direction of this statement is obvious[775]. Hence, we only need to prove the "only if" statement. In other words, we need to prove that if a is primitive, then a lies in the $\mathbf{k}$-linear span of $p_1, p_2, p_3, \ldots$. So let us assume that a is primitive. That is, $\Delta(a) = 1 \otimes a + a \otimes 1$.

For every $x \in \Lambda$ and $y \in \Lambda$, we have (using the Sweedler notation)

$$x^\perp(a) = \sum_{(a)} (x, a_1)\, a_2 = (x,1)\, a + (x,a)\, 1 \qquad \left(\text{since } \sum_{(a)} a_1 \otimes a_2 = \Delta(a) = 1 \otimes a + a \otimes 1\right)$$

and therefore

$$\begin{aligned} (xy, a) &= \Bigg(y, \underbrace{x^\perp(a)}_{=(x,1)a+(x,a)1}\Bigg) \qquad (\text{by Proposition 2.8.2(i)}) \\ &= (y, (x,1)\, a + (x,a)\, 1) = (x,1)(y,a) + (x,a)(y,1) = (x,1)(y,a) + (y,1)(x,a). \end{aligned} \tag{13.101.4}$$

Using this, we can easily obtain $(1,a) = 0$ [776].

Now, using (13.101.4), it is easy to see that

$$(h_\lambda, a) = 0 \qquad \text{for every partition } \lambda \text{ satisfying } \ell(\lambda) \geq 2. \tag{13.101.5}$$

[775] because Proposition 2.3.6(i) shows that each of $p_1, p_2, p_3, \ldots$ is primitive, and therefore every element of their $\mathbf{k}$-linear span is also primitive

[776] Indeed, applying (13.101.4) to $x = 1$ and $y = 1$, we obtain $(1,a) = \underbrace{(1,1)}_{=1}(1,a) + \underbrace{(1,1)}_{=1}(1,a) = (1,a) + (1,a) = 2(1,a)$, so that $(1,a) = 0$, qed.

[777] Now, (13.101.3) becomes

$$\begin{aligned} a &= \sum_{\lambda\in\operatorname{Par}} (h_\lambda, a)\, m_\lambda = \underbrace{\sum_{\substack{\lambda\in\operatorname{Par};\\ \ell(\lambda)=0}} (h_\lambda, a)\, m_\lambda}_{=(h_\varnothing,a)m_\varnothing} + \underbrace{\sum_{\substack{\lambda\in\operatorname{Par};\\ \ell(\lambda)=1}} (h_\lambda, a)\, m_\lambda}_{=\sum_{n\geq 1}(h_{(n)},a)m_{(n)}} + \sum_{\substack{\lambda\in\operatorname{Par};\\ \ell(\lambda)\geq 2}} \underbrace{(h_\lambda, a)}_{\substack{=0\\ \text{(by (13.101.5))}}} m_\lambda \\ &= \left(\underbrace{h_\varnothing}_{=1}, a\right) m_\varnothing + \sum_{n\geq 1} \left(h_{(n)}, a\right) \underbrace{m_{(n)}}_{=p_n} + \underbrace{\sum_{\substack{\lambda\in\operatorname{Par};\\ \ell(\lambda)\geq 2}} 0 m_\lambda}_{=0} = \underbrace{(1, a)}_{=0} m_\varnothing + \sum_{n\geq 1} \left(h_{(n)}, a\right) p_n \\ &= \sum_{n\geq 1} \left(h_{(n)}, a\right) p_n . \end{aligned}$$

Thus, a lies in the $\mathbf{k}$-linear span of $p_1, p_2, p_3, \ldots$. This completes the solution to Exercise 3.1.9.

13.102. **Solution to Exercise 4.1.1.** *Solution to Exercise 4.1.1.*

(a) This is straightforward: Let g_1 and g_2 be two elements of G belonging to the same conjugacy class. Thus, g_1 and g_2 are conjugate. In other words, there exists some $x \in G$ such that $g_1 = x g_2 x^{-1}$. Consider this x.

By the definition of $\operatorname{Ind}_H^G f$, we have

$$\begin{aligned} \left(\operatorname{Ind}_H^G f\right)(g_1) &= \frac{1}{|H|} \sum_{\substack{k\in G:\\ kg_1k^{-1}\in H}} f\left(kg_1k^{-1}\right) = \frac{1}{|H|} \sum_{\substack{k\in G:\\ kxg_2x^{-1}k^{-1}\in H}} f\left(kxg_2x^{-1}k^{-1}\right) \qquad \left(\text{since } g_1 = xg_2x^{-1}\right) \\ &= \frac{1}{|H|} \sum_{\substack{k\in G:\\ kxg_2(kx)^{-1}\in H}} f\left(kxg_2\left(kx\right)^{-1}\right) \qquad \left(\text{since } x^{-1}k^{-1} = (kx)^{-1}\right) \\ &= \frac{1}{|H|} \sum_{\substack{k\in G:\\ kg_2k^{-1}\in H}} f\left(kg_2k^{-1}\right) \end{aligned}$$

(here, we have substituted k for kx in the sum, because the map $G \to G,\ k \to kx$ is a bijection). Compared with

$$\left(\operatorname{Ind}_H^G f\right)(g_2) = \frac{1}{|H|} \sum_{\substack{k\in G:\\ kg_2k^{-1}\in H}} f\left(kg_2k^{-1}\right)$$

(this follows from the definition of $\operatorname{Ind}_H^G f$), this yields $\left(\operatorname{Ind}_H^G f\right)(g_1) = \left(\operatorname{Ind}_H^G f\right)(g_2)$.

Now, forget that we fixed g_1 and g_2. We thus have proven that if g_1 and g_2 are two elements of G belonging to the same conjugacy class, then $\left(\operatorname{Ind}_H^G f\right)(g_1) = \left(\operatorname{Ind}_H^G f\right)(g_2)$. In other words, the map $\operatorname{Ind}_H^G f$ is constant

[777] *Proof of (13.101.5):* Let λ be a partition satisfying $\ell(\lambda) \geq 2$. Write the partition λ in the form $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_\ell)$ with $\ell = \ell(\lambda)$. Then, λ_1, λ_2, ..., λ_ℓ are positive integers. Let ν be the partition $(\lambda_2, \lambda_3, \ldots, \lambda_\ell)$; then, ν is nonempty (since $\ell = \ell(\lambda) \geq 2$), so that $(h_\nu, 1) = 0$ (by (13.101.1), applied to ν instead of λ). Also, $\left(h_{(\lambda_1)}, 1\right) = 0$ (by (13.101.1), applied to (λ_1) instead of λ).

By the definition of h_λ, we have $h_\lambda = h_{\lambda_1} h_{\lambda_2} \cdots h_{\lambda_\ell} = \underbrace{h_{\lambda_1}}_{=h_{(\lambda_1)}} \underbrace{(h_{\lambda_2} h_{\lambda_3} \cdots h_{\lambda_\ell})}_{\substack{=h_\nu\\ (\text{since } \nu=(\lambda_2,\lambda_3,\ldots,\lambda_\ell))}} = h_{(\lambda_1)} h_\nu$. Thus,

$$\begin{aligned} \left(\underbrace{h_\lambda}_{=h_{(\lambda_1)}h_\nu}, a\right) &= \left(h_{(\lambda_1)} h_\nu, a\right) = \underbrace{\left(h_{(\lambda_1)}, 1\right)}_{=0} (h_\nu, a) + \underbrace{(h_\nu, 1)}_{=0} \left(h_{(\lambda_1)}, a\right) \qquad \left(\text{by (13.101.4), applied to } x = h_{(\lambda_1)} \text{ and } y = h_\nu\right) \\ &= 0 + 0 = 0. \end{aligned}$$

This proves (13.101.5).

on conjugacy classes. Hence, $\operatorname{Ind}_H^G f$ is a class function on G. In other words, $\operatorname{Ind}_H^G f \in R_{\mathbb{C}}(G)$. This solves part (a) of the exercise.

(b) We have $G = \bigsqcup_{j \in J} Hj$. Thus, every $k \in G$ can be uniquely written in the form hj for some $j \in J$ and $h \in H$. Hence,

$$\begin{aligned}
\sum_{\substack{k\in G:\\ kgk^{-1}\in H}} f\left(kgk^{-1}\right) &= \underbrace{\sum_{\substack{j\in J;\ h\in H:\\ (hj)g(hj)^{-1}\in H}}}_{\substack{=\sum_{\substack{j\in J;\ h\in H:\\ hjgj^{-1}h^{-1}\in H}} = \sum_{\substack{j\in J;\ h\in H:\\ jgj^{-1}\in H}} \\ \text{(because under the condition that } h\in H\text{,} \\ \text{the relation } hjgj^{-1}h^{-1}\in H \text{ is equivalent} \\ \text{to the relation } jgj^{-1}\in H\text{)}}} f\left(\underbrace{(hj)\,g\,(hj)^{-1}}_{=hjgj^{-1}h^{-1}}\right) \\
&= \underbrace{\sum_{\substack{j\in J;\ h\in H:\\ jgj^{-1}\in H}}}_{=\sum_{\substack{j\in J:\\ jgj^{-1}\in H}} \sum_{h\in H}} \underbrace{f\left(hjgj^{-1}h^{-1}\right)}_{\substack{=f\left(jgj^{-1}\right) \\ \text{(since } f \text{ is a class function on } H\text{,} \\ \text{and } hjgj^{-1}h^{-1} \text{ is } H\text{-conjugate to } jgj^{-1}\text{)}}} \\
&= \sum_{\substack{j\in J:\\ jgj^{-1}\in H}} \underbrace{\sum_{h\in H} f\left(jgj^{-1}\right)}_{=|H| f\left(jgj^{-1}\right)} = |H| \sum_{\substack{j\in J:\\ jgj^{-1}\in H}} f\left(jgj^{-1}\right).
\end{aligned} \tag{13.102.1}$$

Now, the definition of $\operatorname{Ind}_H^G f$ yields

$$\left(\operatorname{Ind}_H^G f\right)(g) = \frac{1}{|H|} \underbrace{\sum_{\substack{k\in G:\\ kgk^{-1}\in H}} f\left(kgk^{-1}\right)}_{=|H| \sum_{\substack{j\in J:\\ jgj^{-1}\in H}} f\left(jgj^{-1}\right)} = \sum_{\substack{j\in J:\\ jgj^{-1}\in H}} f\left(jgj^{-1}\right).$$

This solves part (b) of the exercise.

13.103. **Solution to Exercise 4.1.2.** *Solution to Exercise 4.1.2.* We have $\mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H \cong \mathbb{C}G$ as $(\mathbb{C}G, \mathbb{C}H)$-bimodules, and thus also as $(\mathbb{C}G, \mathbb{C}I)$-bimodules[778].

By the definition of induction, we have $\operatorname{Ind}_I^H U = \mathbb{C}H \otimes_{\mathbb{C}I} U$. But by the definition of induction, we also have

$$\begin{aligned}
\operatorname{Ind}_H^G \operatorname{Ind}_I^H U &= \mathbb{C}G \otimes_{\mathbb{C}H} \underbrace{\operatorname{Ind}_I^H U}_{=\mathbb{C}H \otimes_{\mathbb{C}I} U} = \mathbb{C}G \otimes_{\mathbb{C}H} \left(\mathbb{C}H \otimes_{\mathbb{C}I} U\right) \\
&\cong \underbrace{\left(\mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H\right)}_{\substack{\cong \mathbb{C}G \\ \text{(as } (\mathbb{C}G, \mathbb{C}I)\text{-bimodules)}}} \otimes_{\mathbb{C}I} U \qquad \text{(by the associativity of the tensor product)} \\
&\cong \mathbb{C}G \otimes_{\mathbb{C}I} U = \operatorname{Ind}_I^G U
\end{aligned}$$

(since $\operatorname{Ind}_I^G U = \mathbb{C}G \otimes_{\mathbb{C}I} U$ (by the definition of induction)). This solves Exercise 4.1.2.

---

[778] since the right $\mathbb{C}I$-module structures on $\mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H$ and on $\mathbb{C}G$ are obtained from the respective right $\mathbb{C}H$-module structures by restriction

13.104. **Solution to Exercise 4.1.3.** *Solution to Exercise 4.1.3.* The solution rests upon the following general fact:

Proposition 13.104.1. *Let* $\mathbf{k}$ *be a commutative ring. Let* A, B, C, A', B' *and* C' *be six* $\mathbf{k}$*-algebras. Let* P *be an* (A,B)*-bimodule*[779]. *Let* Q *be a* (B,C)*-bimodule. Let* P' *be an* (A',B')*-bimodule. Let* Q' *be a* (B',C')*-bimodule. Then,*

$$(P \otimes P') \otimes_{B \otimes B'} (Q \otimes Q') \cong (P \otimes_B Q) \otimes (P' \otimes_{B'} Q')$$

as $(A \otimes A', C \otimes C')$*-bimodules. Here, all* $\otimes$ *signs without subscript stand for* $\otimes_{\mathbf{k}}$.

This proposition is proven by straightforward (repeated) application of the universal property of the tensor product. (Of course, the $(A \otimes A', C \otimes C')$-bimodule isomorphism $(P \otimes P') \otimes_{B \otimes B'} (Q \otimes Q') \to (P \otimes_B Q) \otimes (P' \otimes_{B'} Q')$ sends every $(p \otimes p') \otimes_{B \otimes B'} (q \otimes q')$ to $(p \otimes_B q) \otimes (p' \otimes_B q')$.) We leave all details to the reader.

Now, let us come to the solution of Exercise 4.1.3.[780] We want to prove the isomorphism

$$\operatorname{Ind}_{H_1 \times H_2}^{G_1 \times G_2} (U_1 \otimes U_2) \cong \left(\operatorname{Ind}_{H_1}^{G_1} U_1 \right) \otimes \left(\operatorname{Ind}_{H_2}^{G_2} U_2 \right)$$

of $\mathbb{C}[G_1 \times G_2]$-modules. Recalling the definition of Ind, we rewrite this as

$$\mathbb{C}[G_1 \times G_2] \otimes_{\mathbb{C}[H_1 \times H_2]} (U_1 \otimes U_2) \cong (\mathbb{C}G_1 \otimes_{\mathbb{C}H_1} U_1) \otimes (\mathbb{C}G_2 \otimes_{\mathbb{C}H_2} U_2) . \qquad (13.104.1)$$

But Proposition 13.104.1 (applied to $\mathbf{k} = \mathbb{C}$, $A = \mathbb{C}G_1$, $B = \mathbb{C}H_1$, $C = \mathbb{C}$, $A' = \mathbb{C}G_2$, $B' = \mathbb{C}H_2$, $C' = \mathbb{C}$, $P = \mathbb{C}G_1$, $Q = U_1$, $P' = \mathbb{C}G_2$ and $Q' = U_2$) yields

$$(\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \cong (\mathbb{C}G_1 \otimes_{\mathbb{C}H_1} U_1) \otimes (\mathbb{C}G_2 \otimes_{\mathbb{C}H_2} U_2)$$

as $(\mathbb{C}G_1 \otimes \mathbb{C}G_2, \mathbb{C} \otimes \mathbb{C})$-bimodules (thus, as left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-modules). In order to derive (13.104.1) from this isomorphism, we need to realize that:

- there exist algebra isomorphisms $\mathbb{C}[G_1 \times G_2] \to \mathbb{C}G_1 \otimes \mathbb{C}G_2$ and $\mathbb{C}[H_1 \times H_2] \to \mathbb{C}H_1 \otimes \mathbb{C}H_2$ which commute with the canonical inclusion maps $\mathbb{C}[H_1 \times H_2] \to \mathbb{C}[G_1 \times G_2]$ and $\mathbb{C}H_1 \otimes \mathbb{C}H_2 \to \mathbb{C}G_1 \otimes \mathbb{C}G_2$;
- when we identify $\mathbb{C}[H_1 \times H_2]$ with $\mathbb{C}H_1 \otimes \mathbb{C}H_2$ along the isomorphism $\mathbb{C}[H_1 \times H_2] \to \mathbb{C}H_1 \otimes \mathbb{C}H_2$, the $\mathbb{C}H_1 \otimes \mathbb{C}H_2$-module $U_1 \otimes U_2$ becomes exactly the $\mathbb{C}[H_1 \times H_2]$-module $U_1 \otimes U_2$;
- when we identify $\mathbb{C}[G_1 \times G_2]$ with $\mathbb{C}G_1 \otimes \mathbb{C}G_2$ along the isomorphism $\mathbb{C}[G_1 \times G_2] \to \mathbb{C}G_1 \otimes \mathbb{C}G_2$, the $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-module $(\mathbb{C}G_1 \otimes_{\mathbb{C}H_1} U_1) \otimes (\mathbb{C}G_2 \otimes_{\mathbb{C}H_2} U_2)$ becomes exactly the $\mathbb{C}[G_1 \times G_2]$-module $(\mathbb{C}G_1 \otimes_{\mathbb{C}H_1} U_1) \otimes (\mathbb{C}G_2 \otimes_{\mathbb{C}H_2} U_2)$.

These facts are all trivial to verify (of course, the isomorphism $\mathbb{C}[G_1 \times G_2] \to \mathbb{C}G_1 \otimes \mathbb{C}G_2$ is given by sending every $t_{(g_1,g_2)}$ to $t_{g_1} \otimes t_{g_2}$, and similarly for the other isomorphism). Thus, (13.104.1) holds, and the exercise is solved.

13.105. **Solution to Exercise 4.1.4.** *Solution to Exercise 4.1.4.* In the following, we will write g for the element t_g of $\mathbb{C}G$ whenever g is an element of G. This is a relatively common abuse of notation, and it is harmless because the map $G \to \mathbb{C}G$, $g \mapsto t_g$ is an injective homomorphism of multiplicative monoids (so $t_{gh} = t_g t_h$ and $t_1 = 1$, which means that we won't run into ambiguities denoting t_g by g) and because every $\mathbb{C}G$-module M, every $m \in M$ and every $g \in G$ satisfy $gm = t_g m$.

Recall that $\operatorname{Ind}_H^G U$ is defined as the $\mathbb{C}G$-module $\mathbb{C}G \otimes_{\mathbb{C}H} U$, where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}H)$-bimodule.

The $\mathbb{C}$-vector space $\mathbb{C}G$ is endowed with both a $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure (this is the structure used in the definition of $\operatorname{Ind}_H^G U$) and a $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure (this is the structure used in the statement of Exercise 4.1.4). Thus, $\mathbb{C}G$ has a left $\mathbb{C}G$-module structure, a right $\mathbb{C}H$-module structure, a left $\mathbb{C}H$-module structure, and a right $\mathbb{C}G$-module structure. All four of these structures are simply given by multiplication inside $\mathbb{C}G$ (since $\mathbb{C}H$ is a $\mathbb{C}$-subalgebra of $\mathbb{C}G$). Therefore, notations like xy with x and y being two elements

[779] As usual, we understand the notion of a bimodule to be defined over $\mathbf{k}$; that is, the left A-module structure and the right B-module structure of an (A,B)-bimodule must restrict to one and the same $\mathbf{k}$-module structure.

[780] The following solution involves some handwaving: We are going to use certain isomorphisms to identify $\mathbb{C}[G_1 \times G_2]$ with $\mathbb{C}G_1 \otimes \mathbb{C}G_2$ and to identify $\mathbb{C}[H_1 \times H_2]$ with $\mathbb{C}H_1 \otimes \mathbb{C}H_2$. See the solution of Exercise 4.1.15 for an example of how to avoid this kind of handwaving. (Actually, Exercise 4.1.14(b) shows that Exercise 4.1.15 is a generalization of Exercise 4.1.3.)

of $\mathbb{C}G$ or $\mathbb{C}H$ will never be ambiguous: While they might be interpreted in different ways, all of the possible interpretations will produce identical results.

We recall that $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ is the left $\mathbb{C}G$-module consisting of all left $\mathbb{C}H$-module homomorphisms from $\mathbb{C}G$ to U. This uses only the $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure on $\mathbb{C}G$ that was used in the statement of Exercise 4.1.4 (but not the $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure that was used in the definition of $\operatorname{Ind}_H^G U$).

Let J be a system of distinct representatives for the right H-cosets in G. Then, $G = \bigsqcup_{j \in J} Hj$.

We now define a map $\alpha : \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \to \mathbb{C}G \otimes_{\mathbb{C}H} U$ by setting

$$\alpha(f) = \sum_{j \in J} j^{-1} \otimes_{\mathbb{C}H} f(j) \qquad \text{for all } f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U).$$

This α is a map $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \to \operatorname{Ind}_H^G U$ (since $\operatorname{Ind}_H^G U = \mathbb{C}G \otimes_{\mathbb{C}H} U$). It is easy to see that this map α does not depend on the choice of J. (In fact, if j_1 and j_2 are two elements of G lying in the same right H-coset, and if $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$, then it is easy to see that $j_1^{-1} \otimes_{\mathbb{C}H} f(j_1) = j_2^{-1} \otimes_{\mathbb{C}H} f(j_2)$.) In other words, if J' is any system of distinct representatives for the right H-cosets in G (which may and may not be equal to J), then

$$\alpha(f) = \sum_{j \in J'} j^{-1} \otimes_{\mathbb{C}H} f(j) \qquad \text{for all } f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U). \tag{13.105.1}$$

Notice that if $g \in G$ is arbitrary, then $Jg = \{jg \mid j \in J\}$ is also a system of distinct representatives for the right H-cosets in G.

We will show that α is a $\mathbb{C}G$-module isomorphism.

First, let us prove that α is a left $\mathbb{C}G$-module homomorphism. In fact, any $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ and $g \in G$ satisfy

$$\begin{aligned}
\alpha(gf) &= \sum_{j \in J} \underbrace{j^{-1}}_{= g(jg)^{-1}} \otimes_{\mathbb{C}H} \underbrace{(gf)(j)}_{\substack{= f(jg) \\ \text{(by the definition of } gf)}} = \sum_{j \in J} g(jg)^{-1} \otimes_{\mathbb{C}H} f(jg) \\
&= \sum_{j \in Jg} gj^{-1} \otimes_{\mathbb{C}H} f(j) \qquad \text{(here, we substituted } j \text{ for } jg \text{ in the sum)} \\
&= g \cdot \underbrace{\left(\sum_{j \in Jg} j^{-1} \otimes_{\mathbb{C}H} f(j) \right)}_{\substack{= \alpha(f) \\ \text{(by (13.105.1), applied to } J' = Jg)}} = g \cdot \alpha(f).
\end{aligned}$$

The map α is thus a homomorphism of left G-sets. Since α is furthermore $\mathbb{C}$-linear, this yields that α is a left $\mathbb{C}G$-module homomorphism.

We now are going to construct an inverse for α. This will be more cumbersome.

For every $g \in G$ and every $p \in \mathbb{C}G$, we denote by $\epsilon_g(p)$ the g-coordinate of p with respect to the basis G of the $\mathbb{C}$-vector space $\mathbb{C}G$. By the definition of "coordinate", we have

$$q = \sum_{g \in G} \epsilon_g(q) g \qquad \text{for every } q \in \mathbb{C}G. \tag{13.105.2}$$

For every $g \in G$, we have defined a map $\epsilon_g : \mathbb{C}G \to \mathbb{C}$ (because we have defined an element $\epsilon_g(p)$ for every $p \in \mathbb{C}G$). This map ϵ_g is $\mathbb{C}$-linear. Here are some simple properties of this map:

- For every $g \in G$ and $h \in G$, we have

$$\epsilon_g(h) = \delta_{g,h}. \tag{13.105.3}$$

[781]

- We have

$$\epsilon_1(pq) = \epsilon_1(qp) \qquad \text{for all } p \in \mathbb{C}G \text{ and } q \in \mathbb{C}G. \tag{13.105.4}$$

[781] *Proof.* Let $g \in G$ and $h \in G$. Then, $\epsilon_g(h)$ is defined as the g-coordinate of h with respect to the basis G of the $\mathbb{C}$-vector space $\mathbb{C}G$. This g-coordinate is precisely 1 (since h is an element of this basis G). Thus, $\epsilon_g(h) = 1$, qed.

[782]

- Moreover,

$$\epsilon_1\left(g^{-1}q\right) = \epsilon_g\left(q\right) \qquad \text{for every } g \in G \text{ and } q \in \mathbb{C}G. \tag{13.105.5}$$

[783]

Now, fix $q \in \mathbb{C}G$ and $u \in U$. We let $f_{q,u}$ be the map $\mathbb{C}G \to U$ defined by

$$f_{q,u}\left(p\right) = \sum_{h\in H} \epsilon_1\left(hpq\right) h^{-1}u \qquad \text{for every } p \in \mathbb{C}G. \tag{13.105.6}$$

It is obvious that this map $f_{q,u}$ is $\mathbb{C}$-linear. We will show that $f_{q,u}$ is a left $\mathbb{C}H$-module homomorphism.

The map $f_{q,u}$ is a homomorphism of left H-sets[784]. Since $f_{q,u}$ is furthermore $\mathbb{C}$-linear, this yields that $f_{q,u}$ is a left $\mathbb{C}H$-module homomorphism. Hence, $f_{q,u} \in \operatorname{Hom}_{\mathbb{C}H}\left(\mathbb{C}G, U\right)$.

Now, forget that we fixed q and u. We thus have defined a map $f_{q,u} \in \operatorname{Hom}_{\mathbb{C}H}\left(\mathbb{C}G, U\right)$ for every $q \in \mathbb{C}G$ and $u \in U$. It is easy to see that this map $f_{q,u}$ depends $\mathbb{C}$-linearly on each of q and u. Now, define a map $\widetilde{\beta} : \mathbb{C}G \times U \to \operatorname{Hom}_{\mathbb{C}H}\left(\mathbb{C}G, U\right)$ by

$$\widetilde{\beta}\left(q, u\right) = f_{q,u} \qquad \text{for every } \left(q, u\right) \in \mathbb{C}G \times U.$$

Then, $\widetilde{\beta}$ is a $\mathbb{C}$-bilinear map (because $\widetilde{\beta}\left(q, u\right) = f_{q,u}$ depends $\mathbb{C}$-linearly on each of q and u). We are now going to prove that the map $\widetilde{\beta}$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U.

In fact, every $h' \in H$, $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\widetilde{\beta}\left(q, h'u\right) = \widetilde{\beta}\left(qh', u\right). \tag{13.105.7}$$

[782] *Proof.* Let $p \in \mathbb{C}G$ and $q \in \mathbb{C}G$. We need to prove the equality (13.105.4). This equality is $\mathbb{C}$-linear in each of p and q, and thus we can WLOG assume that both p and q belong to the basis G of the $\mathbb{C}$-vector space $\mathbb{C}G$. Assume this. Then, pq and qp belong to G as well. Hence, (13.105.3) yields $\epsilon_1\left(pq\right) = \delta_{1,pq}$ and $\epsilon_1\left(qp\right) = \delta_{1,qp}$. But p and q are elements of the group G. Hence, we have $1 = pq$ if and only if $1 = qp$ (because both of these statements are equivalent to $q = p^{-1}$). Therefore, $\delta_{1,pq} = \delta_{1,qp}$, so that $\epsilon_1\left(pq\right) = \delta_{1,pq} = \delta_{1,qp} = \epsilon_1\left(qp\right)$. This proves (13.105.4).

[783] *Proof.* Let $g \in G$ and $q \in \mathbb{C}G$. We need to prove the equality (13.105.5). This equality is $\mathbb{C}$-linear in q, and thus we can WLOG assume that q belongs to the basis G of the $\mathbb{C}$-vector space $\mathbb{C}G$. Assume this. Then, $g^{-1}q \in G$ as well. Hence, (13.105.3) yields $\epsilon_1\left(g^{-1}q\right) = \delta_{1,g^{-1}q}$ and $\epsilon_g\left(q\right) = \delta_{g,q}$. But g and q are elements of the group G. Hence, we have $1 = g^{-1}q$ if and only if $g = q$. Therefore, $\delta_{1,g^{-1}q} = \delta_{g,q}$, so that $\epsilon_1\left(g^{-1}q\right) = \delta_{1,g^{-1}q} = \delta_{g,q} = \epsilon_g\left(q\right)$. This proves (13.105.5).

[784] *Proof.* In fact, for every $h' \in H$ and every $p \in \mathbb{C}G$, we have

$$\begin{aligned}
f_{q,u}\left(h'p\right) &= \sum_{h\in H} \epsilon_1\left(hh'pq\right) h^{-1}u \qquad \text{(by the definition of } f_{q,u}\text{)} \\
&= \sum_{h\in H} \epsilon_1\left(h \underbrace{\left(h'\right)^{-1} h'}_{=1} pq\right) \underbrace{\left(h\left(h'\right)^{-1}\right)^{-1}}_{=\left(\left(h'\right)^{-1}\right)^{-1}h^{-1}=h'h^{-1}} u \\
&\qquad \left(\begin{array}{c} \text{here, we have substituted } h\left(h'\right)^{-1} \text{ for } h \text{ in the sum,} \\ \text{because the map } H \to H,\ h \mapsto h\left(h'\right)^{-1} \text{ is a bijection} \\ \text{(since } H \text{ is a group and since } h' \in H\text{)} \end{array}\right) \\
&= \sum_{h\in H} \epsilon_1\left(hpq\right) h'h^{-1}u = h' \cdot \underbrace{\sum_{h\in H} \epsilon_1\left(hpq\right) h^{-1}u}_{\substack{=f_{q,u}(p) \\ \text{(by (13.105.6))}}} = h' \cdot f_{q,u}\left(p\right).
\end{aligned}$$

In other words, $f_{q,u}$ is a homomorphism of left H-sets, qed.

[785] As a consequence of this, every $r \in \mathbb{C}H$, $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\widetilde{\beta}(q, ru) = \widetilde{\beta}(qr, u) \tag{13.105.9}$$

(by $\mathbb{C}$-bilinearity of $\widetilde{\beta}$). In other words, the map $\widetilde{\beta}$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U. Hence, by the universal property of the tensor product, we conclude that there exists a unique $\mathbb{C}$-linear map $\beta : \mathbb{C}G \otimes_{\mathbb{C}H} U \to \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ such that every $(q, u) \in \mathbb{C}G \times U$ satisfies

$$\beta(q \otimes_{\mathbb{C}H} u) = \widetilde{\beta}(q, u). \tag{13.105.10}$$

Consider this map β. Clearly, every $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\beta(q \otimes_{\mathbb{C}H} u) = \widetilde{\beta}(q, u) = f_{q,u} \qquad \left(\text{by the definition of } \widetilde{\beta}\right).$$

Hence, every $q \in \mathbb{C}G$, $u \in U$ and $p \in \mathbb{C}G$ satisfy

$$\left(\underbrace{\beta(q \otimes_{\mathbb{C}H} u)}_{=f_{q,u}}\right)(p) = f_{q,u}(p) = \sum_{h \in H} \epsilon_1(hpq)\, h^{-1} u \tag{13.105.11}$$

(by (13.105.6)).

We shall now show that the maps α and β are mutually inverse. To do so, we will show that $\alpha \circ \beta = \mathrm{id}$ and $\beta \circ \alpha = \mathrm{id}$.

[785] *Proof of* (13.105.7)*:* Let $h' \in H$, $q \in \mathbb{C}G$ and $u \in U$. Then, the map $H \to H,\ h \mapsto h'h$ is a bijection (since H is a group). Now, let $p \in \mathbb{C}G$. The definition of $\widetilde{\beta}$ yields $\widetilde{\beta}(q, h'u) = f_{q,h'u}$. Hence,

$$\begin{aligned}
\left(\underbrace{\widetilde{\beta}(q, h'u)}_{=f_{q,h'u}}\right)(p) &= f_{q,h'u}(p) = \sum_{h \in H} \epsilon_1(hpq)\, h^{-1} h' u \qquad \left(\text{by the definition of } f_{q,h'u}\right) \\
&= \sum_{h \in H} \epsilon_1(h'hpq) \underbrace{(h'h)^{-1}}_{=h^{-1}(h')^{-1}} h' u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } h'h \text{ for } h \text{ in the sum,} \\ \text{since the map } H \to H,\ h \mapsto h'h \text{ is a bijection}\end{array}\right) \\
&= \sum_{h \in H} \underbrace{\epsilon_1(h'hpq)}_{\substack{=\epsilon_1(hpqh') \\ \text{(by (13.105.4), applied to} \\ h' \text{ and } hpq \text{ instead of } p \text{ and } q)}} h^{-1} \underbrace{(h')^{-1} h'}_{=1} u \\
&= \sum_{h \in H} \epsilon_1(hpqh')\, h^{-1} u. \qquad (13.105.8)
\end{aligned}$$

But the definition of $\widetilde{\beta}$ also yields $\widetilde{\beta}(qh', u) = f_{qh',u}$. Hence,

$$\begin{aligned}
\left(\widetilde{\beta}(qh', u)\right)(p) &= f_{qh',u}(p) = \sum_{h \in H} \epsilon_1(hpqh')\, h^{-1} u \qquad \left(\text{by the definition of } f_{qh',u}\right) \\
&= \left(\widetilde{\beta}(q, h'u)\right)(p) \qquad (\text{by (13.105.8)}).
\end{aligned}$$

Now, forget that we fixed p. We have thus proven that $\left(\widetilde{\beta}(qh', u)\right)(p) = \left(\widetilde{\beta}(q, h'u)\right)(p)$ for every $p \in \mathbb{C}G$. In other words, $\widetilde{\beta}(qh', u) = \widetilde{\beta}(q, h'u)$, so that $\widetilde{\beta}(q, h'u) = \widetilde{\beta}(qh', u)$. This proves (13.105.7).

Let us first show that $\alpha \circ \beta = \operatorname{id}$. In fact, every $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\begin{aligned}
(\alpha\circ\beta)(q\otimes_{\mathbb{C}H}u) &= \alpha(\beta(q\otimes_{\mathbb{C}H}u)) = \sum_{j\in J} j^{-1}\otimes_{\mathbb{C}H} \underbrace{(\beta(q\otimes_{\mathbb{C}H}u))(j)}_{\substack{=\sum_{h\in H}\epsilon_1(hjq)h^{-1}u \\ \text{(by (13.105.11), applied to } p=j)}} \\
&\qquad \text{(by the definition of } \alpha\text{)} \\
&= \sum_{j\in J} j^{-1}\otimes_{\mathbb{C}H}\left(\sum_{h\in H}\epsilon_1(hjq)\,h^{-1}u\right) = \sum_{j\in J}\sum_{h\in H}\epsilon_1(hjq) \underbrace{j^{-1}\otimes_{\mathbb{C}H}h^{-1}u}_{\substack{=j^{-1}h^{-1}\otimes_{\mathbb{C}H}u \\ \text{(since } h^{-1}\in H \text{ (since } h\in H\text{))}}} \\
&= \sum_{j\in J}\sum_{h\in H}\epsilon_1(hjq)\underbrace{j^{-1}h^{-1}}_{=(hj)^{-1}}\otimes_{\mathbb{C}H}u = \sum_{j\in J}\sum_{h\in H}\epsilon_1(hjq)(hj)^{-1}\otimes_{\mathbb{C}H}u \\
&= \underbrace{\sum_{j\in J}\sum_{g\in Hj}}_{\substack{=\sum_{g\in G} \\ \text{(since } \bigsqcup_{j\in J}Hj=G\text{)}}} \epsilon_1(gq)\,g^{-1}\otimes_{\mathbb{C}H}u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } g \text{ for } hj \text{ in the second sum, since the map} \\ H\to Hj,\ h\mapsto hj \text{ is a bijection (because } G \text{ is a group)}\end{array}\right) \\
&= \sum_{g\in G}\epsilon_1(gq)\,g^{-1}\otimes_{\mathbb{C}H}u = \sum_{g\in G}\underbrace{\epsilon_1(g^{-1}q)}_{\substack{=\epsilon_g(q) \\ \text{(by (13.105.5))}}}\underbrace{(g^{-1})^{-1}}_{=g}\otimes_{\mathbb{C}H}u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } g^{-1} \text{ for } g \text{ in the sum, since the map} \\ G\to G,\ g\mapsto g^{-1} \text{ is a bijection (since } G \text{ is a group)}\end{array}\right) \\
&= \sum_{g\in G}\epsilon_g(q)\,g\otimes_{\mathbb{C}H}u = \underbrace{\left(\sum_{g\in G}\epsilon_g(q)\,g\right)}_{\substack{=q \\ \text{(by (13.105.2))}}}\otimes_{\mathbb{C}H}u \\
&= q\otimes_{\mathbb{C}H}u = \operatorname{id}(q\otimes_{\mathbb{C}H}u).
\end{aligned}$$

Thus, the two maps $\alpha \circ \beta$ and id are equal on every pure tensor. Since these two maps are $\mathbb{C}$-linear, this yields that $\alpha \circ \beta = \operatorname{id}$.

Next, we are going to show that $\beta \circ \alpha = \operatorname{id}$.

Let $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. Let $p \in \mathbb{C}G$. The map f is left $\mathbb{C}H$-linear (since $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$), hence $\mathbb{C}$-linear. We have $\alpha(f) = \sum_{j\in J} j^{-1} \otimes_{\mathbb{C}H} f(j)$ (by the definition of α). Applying the map β to this equality, we obtain

$$\beta(\alpha(f)) = \beta\left(\sum_{j\in J} j^{-1}\otimes_{\mathbb{C}H} f(j)\right) = \sum_{j\in J}\beta\left(j^{-1}\otimes_{\mathbb{C}H} f(j)\right)$$

(since β is a $\mathbb{C}$-linear map). Thus,

$$
\begin{aligned}
&\underbrace{\left(\beta\left(\alpha\left(f\right)\right)\right)}_{=\sum_{j\in J}\beta\left(j^{-1}\otimes_{\mathbb{C}H}f\left(j\right)\right)}\left(p\right) \\
&=\left(\sum_{j\in J}\beta\left(j^{-1}\otimes_{\mathbb{C}H}f\left(j\right)\right)\right)\left(p\right)=\sum_{j\in J}\underbrace{\left(\beta\left(j^{-1}\otimes_{\mathbb{C}H}f\left(j\right)\right)\right)\left(p\right)}_{\substack{=\sum_{h\in H}\epsilon_1\left(hpj^{-1}\right)h^{-1}f\left(j\right)\\ \text{(by (13.105.11), applied to}\\ q=j^{-1}\text{ and }u=f\left(j\right))}} \\
&=\sum_{j\in J}\sum_{h\in H}\epsilon_1\left(hpj^{-1}\right)h^{-1}f\left(j\right)=\sum_{j\in J}\sum_{h\in H}\underbrace{\epsilon_1\left(h^{-1}pj^{-1}\right)}_{\substack{=\epsilon_1\left(j^{-1}h^{-1}p\right)\\ \text{(by (13.105.4), applied to}\\ h^{-1}p\text{ and }j^{-1}\text{ instead of }p\text{ and }q)}}\underbrace{\left(h^{-1}\right)^{-1}}_{=h}f\left(j\right) \\
&\qquad\left(\begin{array}{c}\text{here, we substituted }h^{-1}\text{ for }h\text{ in the second sum,}\\ \text{since the map }H\to H,\ h\mapsto h^{-1}\text{ is a bijection}\\ \text{(because }H\text{ is a group)}\end{array}\right) \\
&=\sum_{j\in J}\sum_{h\in H}\epsilon_1\left(\underbrace{j^{-1}h^{-1}}_{=\left(hj\right)^{-1}}p\right)\underbrace{hf\left(j\right)}_{\substack{=f\left(hj\right)\\ \text{(since }f\text{ is left }\mathbb{C}H\text{-linear and since }h\in H\subset\mathbb{C}H)}} \\
&=\sum_{j\in J}\sum_{h\in H}\epsilon_1\left(\left(hj\right)^{-1}p\right)f\left(hj\right)=\underbrace{\sum_{j\in J}\sum_{g\in Hj}}_{\substack{=\sum_{g\in G}\\ \text{(since }\bigsqcup_{j\in J}Hj=G)}}\epsilon_1\left(g^{-1}p\right)f\left(g\right) \\
&\qquad\left(\begin{array}{c}\text{here, we substituted }g\text{ for }hj\text{ in the second sum, since the map}\\ H\to Hj,\ h\mapsto hj\text{ is a bijection (because }G\text{ is a group)}\end{array}\right) \\
&=\sum_{g\in G}\underbrace{\epsilon_1\left(g^{-1}p\right)}_{\substack{=\epsilon_g\left(p\right)\\ \text{(by (13.105.5), applied to }q=p)}}f\left(g\right)=\sum_{g\in G}\epsilon_g\left(p\right)f\left(g\right) \\
&=f\left(\underbrace{\sum_{g\in G}\epsilon_g\left(p\right)g}_{\substack{=p\\ \text{(by (13.105.2))}}}\right)\qquad\left(\text{since }f\text{ is }\mathbb{C}\text{-linear}\right) \\
&=f\left(p\right).
\end{aligned}
$$

Now, forget that we fixed p. We thus have proven that $\left(\beta\left(\alpha\left(f\right)\right)\right)\left(p\right)=f\left(p\right)$ for every $p\in\mathbb{C}G$. In other words, $\beta\left(\alpha\left(f\right)\right)=f$. Hence, $\left(\beta\circ\alpha\right)\left(f\right)=\beta\left(\alpha\left(f\right)\right)=f=\operatorname{id}\left(f\right)$.

Since we have shown this for every f, we can thus conclude that $\beta\circ\alpha=\operatorname{id}$. Combined with $\alpha\circ\beta=\operatorname{id}$, this yields that the maps α and β are mutually inverse. Hence, the map α is invertible, and thus a left $\mathbb{C}G$-module isomorphism (as we already know that α is a left $\mathbb{C}G$-module homomorphism). Hence, $\operatorname{Hom}_{\mathbb{C}H}\left(\mathbb{C}G,U\right)\cong\mathbb{C}G\otimes_{\mathbb{C}H}U=\operatorname{Ind}_H^G U$ as left $\mathbb{C}G$-modules. This solves Exercise 4.1.4.

Remark: In our solution, we explicitly constructed a $\mathbb{C}G$-module isomorphism $\alpha:\operatorname{Hom}_{\mathbb{C}H}\left(\mathbb{C}G,U\right)\to\operatorname{Ind}_H^G U$. This isomorphism is functorial with respect to U. It is also independent on the choice of J (this is not immediately clear from its definition, but it can be shown very easily, by observing that the tensor $j^{-1}\otimes_{\mathbb{C}H}f\left(j\right)$ for $j\in G$ depends only on the coset Hj and not on j itself). One might ask whether this isomorphism is functorial in G and H; but to make sense of this question, one has to define the category with respect to which this functoriality is to be understood. I don't know a good answer.

It is also worth noting that in our solution, $\mathbb{C}$ could be replaced by any commutative ring. We used neither that $\mathbb{C}$ is a field, nor that $\mathbb{C}$ has characteristic 0.

13.106. **Solution to Exercise 4.1.6.** *Solution to Exercise 4.1.6.* Consider the $\mathbb{C}G$-module $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)$ defined as in Exercise 4.1.4. Then, Exercise 4.1.4 (applied to V instead of U) yields that this module $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)$ is isomorphic to $\operatorname{Ind}_H^G V$. That is, $\operatorname{Ind}_H^G V \cong \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)$. Hence, $\operatorname{Hom}_{\mathbb{C}G}\left(U, \operatorname{Ind}_H^G V\right) \cong \operatorname{Hom}_{\mathbb{C}G}(U, \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V))$. But (4.1.8) (applied to $R = \mathbb{C}G$, $S = \mathbb{C}H$, $A = \mathbb{C}G$, $B = U$ and $C = V$) yields $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G \otimes_{\mathbb{C}G} U, V) \cong \operatorname{Hom}_{\mathbb{C}G}(U, \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V))$. Altogether, we thus have

$$\operatorname{Hom}_{\mathbb{C}G}\left(U, \operatorname{Ind}_H^G V\right) \cong \operatorname{Hom}_{\mathbb{C}G}(U, \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)) \cong \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G \otimes_{\mathbb{C}G} U, V).$$

It remains to see what the $\mathbb{C}H$-module $\mathbb{C}G \otimes_{\mathbb{C}G} U$ is. By the basic properties of tensor products, the $\mathbb{C}H$-module $\mathbb{C}G \otimes_{\mathbb{C}G} U$ is isomorphic to the $\mathbb{C}H$-module obtained by restricting the action of $\mathbb{C}G$ on the $\mathbb{C}G$-module U to the subalgebra $\mathbb{C}H$. Since this latter $\mathbb{C}H$-module is precisely $\operatorname{Res}_H^G U$ (in fact, this is how $\operatorname{Res}_H^G U$ was defined!), this rewrites as follows: The $\mathbb{C}H$-module $\mathbb{C}G \otimes_{\mathbb{C}G} U$ is isomorphic to $\operatorname{Res}_H^G U$. In other words, $\mathbb{C}G \otimes_{\mathbb{C}G} U \cong \operatorname{Res}_H^G U$. Now,

$$\operatorname{Hom}_{\mathbb{C}G}\left(U, \operatorname{Ind}_H^G V\right) \cong \operatorname{Hom}_{\mathbb{C}H}\left(\underbrace{\mathbb{C}G \otimes_{\mathbb{C}G} U}_{\cong \operatorname{Res}_H^G U}, V\right) \cong \operatorname{Hom}_{\mathbb{C}H}\left(\operatorname{Res}_H^G U, V\right).$$

This solves the exercise.

13.107. **Solution to Exercise 4.1.9.** *Solution to Exercise 4.1.9.* In the following, a "Hom" symbol without a subscript means "$\operatorname{Hom}_{\mathbb{C}}$" (rather than "$\operatorname{Hom}_{\mathbb{C}G}$" or whatever other meaning this symbol could possibly have in the context).

If G is a group and if M and N are two $\mathbb{C}G$-modules, then $\operatorname{Hom}(M, N)$ becomes a $\mathbb{C}G$-module, with G acting as follows: If $g \in G$ and $f \in \operatorname{Hom}(M, N)$, then $t_g f$ is the $\mathbb{C}$-linear map $M \to N$ sending every $m \in M$ to $t_g f\left(t_{g^{-1}} m\right)$. This $\mathbb{C}G$-module structure is precisely the one we know from Remark 1.4.11.

Now, it is well-known (and straightforward to verify) that every two $\mathbb{C}G$-modules M and N satisfy

$$\operatorname{Hom}_{\mathbb{C}G}(M, N) = (\operatorname{Hom}(M, N))^G \tag{13.107.1}$$

(where we regard $\operatorname{Hom}_{\mathbb{C}G}(M, N)$ as a $\mathbb{C}$-vector subspace of $\operatorname{Hom}(M, N)$ because every $\mathbb{C}G$-linear map $M \to N$ is a $\mathbb{C}$-linear map $M \to N$).

Let us now come to the solution of the exercise.

(a) Let ψ denote the $\mathbb{C}$-linear map

$$\operatorname{Hom}(V_1, W_1) \otimes \operatorname{Hom}(V_2, W_2) \to \operatorname{Hom}(V_1 \otimes V_2, W_1 \otimes W_2)$$

sending each tensor $f \otimes g$ to the tensor product $f \otimes g$ of homomorphisms. This map ψ is completely independent of G_1 and G_2 (it is defined whenever V_1, V_2, W_1 and W_2 are four $\mathbb{C}$-vector spaces) and is a vector space isomorphism (this is a basic fact from linear algebra, relying only on the finite-dimensionality of V_1, V_2, W_1 and W_2). But we can regard $\operatorname{Hom}(V_1, W_1)$ as a $\mathbb{C}G_1$-module, $\operatorname{Hom}(V_2, W_2)$ as a $\mathbb{C}G_2$-module and $\operatorname{Hom}(V_1 \otimes V_2, W_1 \otimes W_2)$ as a $\mathbb{C}[G_1 \times G_2]$-module. Then, the map ψ is a homomorphism of $\mathbb{C}[G_1 \times G_2]$-modules[786]. Hence, this map ψ must be an isomorphism of $\mathbb{C}[G_1 \times G_2]$-modules (being a vector space isomorphism). As a consequence, it sends the $G_1 \times G_2$-fixed space of its domain to the $G_1 \times G_2$-fixed space of its target:

$$\psi\left((\operatorname{Hom}(V_1, W_1) \otimes \operatorname{Hom}(V_2, W_2))^{G_1 \times G_2}\right) = (\operatorname{Hom}(V_1 \otimes V_2, W_1 \otimes W_2))^{G_1 \times G_2}.$$

[786] This is easy to verify by checking that $t_{(h_1,h_2)}(\psi(f \otimes g)) = \psi\left(t_{h_1} f \otimes t_{h_2} g\right)$ for all $(h_1, h_2) \in G_1 \times G_2$, $f \in \operatorname{Hom}(V_1, W_1)$ and $g \in \operatorname{Hom}(V_2, W_2)$.

Since

$$\begin{aligned}
&\left(\operatorname{Hom}\left(V_1,W_1\right)\otimes\operatorname{Hom}\left(V_2,W_2\right)\right)^{G_1\times G_2}\\
&= \underbrace{\left(\operatorname{Hom}\left(V_1,W_1\right)\right)^{G_1}}_{\substack{=\operatorname{Hom}_{\mathbb{C}G_1}(V_1,W_1)\\ \text{(by (13.107.1),}\\ \text{applied to } G=G_1,\ M=V_1 \text{ and } N=W_1)}} \otimes \underbrace{\left(\operatorname{Hom}\left(V_2,W_2\right)\right)^{G_2}}_{\substack{=\operatorname{Hom}_{\mathbb{C}G_2}(V_2,W_2)\\ \text{(by (13.107.1),}\\ \text{applied to } G=G_2,\ M=V_2 \text{ and } N=W_2)}}\\
&\qquad\left(\begin{array}{c}\text{by (4.1.15), applied to } K_1=G_1,\ K_2=G_2,\\ U_1=\operatorname{Hom}\left(V_1,W_1\right) \text{ and } U_2=\operatorname{Hom}\left(V_2,W_2\right)\end{array}\right)\\
&= \operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\otimes\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right),
\end{aligned}$$

this rewrites as

$$\psi\left(\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\otimes\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)\right)=\left(\operatorname{Hom}\left(V_1\otimes V_2,W_1\otimes W_2\right)\right)^{G_1\times G_2}.$$

Hence, the isomorphism ψ restricts to an isomorphism from $\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\otimes\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)$ to $\left(\operatorname{Hom}\left(V_1\otimes V_2,W_1\otimes W_2\right)\right)^{G_1\times G_2}$. This restriction is precisely the $\mathbb{C}$-linear map

$$\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\otimes\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)\to\operatorname{Hom}_{\mathbb{C}[G_1\times G_2]}\left(V_1\otimes V_2,W_1\otimes W_2\right)$$

sending each tensor $f\otimes g$ to the tensor product $f\otimes g$ of homomorphisms (i.e., the map alleged to be an isomorphism in the statement of the exercise). So we know now that this map is an isomorphism. This solves Exercise 4.1.9(a).

(b) Let G_1 and G_2 be two groups. Let V_i and W_i be finite-dimensional $\mathbb{C}G_i$-modules for every $i\in\{1,2\}$. Exercise 4.1.9(a) provides a vector space isomorphism from $\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\otimes\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)$ to $\operatorname{Hom}_{\mathbb{C}[G_1\times G_2]}\left(V_1\otimes V_2,W_1\otimes W_2\right)$. As a consequence,

$$\begin{aligned}
&\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\otimes\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)\right)\\
&=\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}[G_1\times G_2]}\left(V_1\otimes V_2,W_1\otimes W_2\right)\right). \qquad (13.107.2)
\end{aligned}$$

Applying (4.1.1) to G_1, V_1 and W_1 instead of G, V_1 and V_2, we obtain

$$\left(\chi_{V_1},\chi_{W_1}\right)_{G_1}=\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\right). \qquad (13.107.3)$$

Applying (4.1.1) to G_2, V_2 and W_2 instead of G, V_1 and V_2, we obtain

$$\left(\chi_{V_2},\chi_{W_2}\right)_{G_2}=\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)\right). \qquad (13.107.4)$$

Applying (4.1.1) to $G_1\times G_2$, $V_1\otimes V_2$ and $W_1\otimes W_2$ instead of G, V_1 and V_2, we obtain

$$\begin{aligned}
\left(\chi_{V_1\otimes V_2},\chi_{W_1\otimes W_2}\right)_{G_1\times G_2}&=\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}[G_1\times G_2]}\left(V_1\otimes V_2,W_1\otimes W_2\right)\right)\\
&=\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\otimes\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)\right) \qquad \text{(by (13.107.2))}\\
&=\underbrace{\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_1}\left(V_1,W_1\right)\right)}_{\substack{=\left(\chi_{V_1},\chi_{W_1}\right)_{G_1}\\ \text{(by (13.107.3))}}}\cdot\underbrace{\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_2}\left(V_2,W_2\right)\right)}_{\substack{=\left(\chi_{V_2},\chi_{W_2}\right)_{G_2}\\ \text{(by (13.107.4))}}}\\
&=\left(\chi_{V_1},\chi_{W_1}\right)_{G_1}\left(\chi_{V_2},\chi_{W_2}\right)_{G_2}.
\end{aligned}$$

This proves (4.1.2). Thus, Exercise 4.1.9(b) is solved.

13.108. **Solution to Exercise 4.1.10.** *Solution to Exercise 4.1.10.* If A and B are two algebras, P is a (B,A)-bimodule and Q is a left B-module, then $\operatorname{Hom}_B(P,Q)$ is a left A-module. Consequently, $\operatorname{Hom}_{\mathbb{C}H}(CG,U)$ is a left $\mathbb{C}G$-module, and $\operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}\left[G/K\right],U^{H\cap K}\right)$ is a left $\mathbb{C}\left[G/K\right]$-module. Exercise 4.1.4 yields that the $\mathbb{C}G$-module $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G,U)$ is isomorphic to $\operatorname{Ind}_H^G U$. In other words,

$$\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G,U)\cong\operatorname{Ind}_H^G U \qquad \text{as } \mathbb{C}G\text{-modules}. \qquad (13.108.1)$$

Also, Exercise 4.1.4 (applied to G/K, $H/(H\cap K)$ and $U^{H\cap K}$ instead of G, H and U) yields that the $\mathbb{C}\left[G/K\right]$-module $\operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}\left[G/K\right],U^{H\cap K}\right)$ is isomorphic to $\operatorname{Ind}_{H/(H\cap K)}^{G/K}\left(U^{H\cap K}\right)$. In other words,

$$\operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}\left[G/K\right],U^{H\cap K}\right)\cong\operatorname{Ind}_{H/(H\cap K)}^{G/K}\left(U^{H\cap K}\right) \qquad \text{as } \mathbb{C}\left[G/K\right]\text{-modules}. \qquad (13.108.2)$$

But we also have

$$(\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))^K \cong \operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}[G/K], U^{H\cap K}\right) \qquad \text{as } \mathbb{C}[G/K]\text{-modules.} \tag{13.108.3}$$

Here is just a brief sketch of the proof of (13.108.3): Let π be the canonical projection $G \to G/K$, and let $\mathbb{C}[\pi]$ be the $\mathbb{C}$-linear map $\mathbb{C}G \to \mathbb{C}[G/K]$ obtained by $\mathbb{C}$-linearly extending π. Clearly, $\mathbb{C}[\pi]$ is a surjective $\mathbb{C}G$-linear $\mathbb{C}$-algebra homomorphism, and we have

$$\begin{aligned}
\ker(\mathbb{C}[\pi]) &= \langle g - g' \mid g \in G,\ g' \in G,\ gK = g'K\rangle && (13.108.4)\\
&= \langle g - gk \mid g \in G,\ k \in K\rangle && (13.108.5)\\
&= \langle g - g' \mid g \in G,\ g' \in G,\ Kg = Kg'\rangle && (13.108.6)\\
&= \langle g - kg \mid g \in G,\ k \in K\rangle && (13.108.7)
\end{aligned}$$

(where the $\langle\cdot\rangle$ brackets stand for "$\mathbb{C}$-span").

Let f be an element of $(\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))^K$. Then, $f \in (\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))^K \subset \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ is $\mathbb{C}H$-linear, and it can easily be shown that $\ker(\mathbb{C}[\pi]) \subset \ker f$ [787]. Hence, the map f factors through the surjective map $\mathbb{C}[\pi]$. The resulting map $\mathbb{C}[G/K] \to U$ is a $\mathbb{C}H$-module homomorphism (since $\mathbb{C}[\pi]$ and f were both $\mathbb{C}H$-linear), and it is easy to see that its image (i.e., the image of f) is contained in $U^{H\cap K}$ [788]. Hence, this map factors through the canonical inclusion $U^{H\cap K} \to U$, leaving behind a map $\mathbb{C}[G/K] \to U^{H\cap K}$ which we denote by $\Phi(f)$. This resulting map $\Phi(f)$ turns out to be $\mathbb{C}[H/(H\cap K)]$-linear[789], thus belongs to $\operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}[G/K], U^{H\cap K}\right)$. Since this holds for every f, we thus obtain a $\mathbb{C}$-linear map

$$\begin{aligned}
(\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))^K &\to \operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}[G/K], U^{H\cap K}\right),\\
f &\mapsto \Phi(f).
\end{aligned}$$

This map is invertible[790] and $\mathbb{C}[G/K]$-linear[791], therefore an isomorphism of $\mathbb{C}[G/K]$-modules. This proves (13.108.3). All steps that were left to the reader are straightforward.

Now,

$$\begin{aligned}
\Bigg(\underbrace{\operatorname{Ind}_H^G U}_{\substack{\cong \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G,U) \text{ as } \mathbb{C}G\text{-modules}\\ (\text{by } (13.108.1))}}\Bigg)^K &\cong (\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))^K\\
&\cong \operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}[G/K], U^{H\cap K}\right) \qquad (\text{by } (13.108.3))\\
&\cong \operatorname{Ind}_{H/(H\cap K)}^{G/K}\left(U^{H\cap K}\right) \qquad (\text{by } (13.108.2))
\end{aligned}$$

as $\mathbb{C}[G/K]$-modules. This solves Exercise 4.1.10.

[787] Indeed, $f \in (\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))^K$. Hence, every $k \in K$ satisfies $kf = f$. Thus, every $g \in G$ and $k \in K$ satisfy $(kf)(g) = f(g)$. But since $(kf)(g) = f(gk)$ (by the definition of the action of G on $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$), this becomes $f(gk) = f(g)$, so that $f(g - gk) = 0$. The map f therefore annihilates $g - gk$ for all $g \in G$ and $k \in K$. Due to (13.108.5), this yields $f(\ker(\mathbb{C}[\pi])) = 0$, so that $\ker(\mathbb{C}[\pi]) \subset \ker f$, qed.

[788] *Proof.* We want to show that the image of f is contained in $U^{H\cap K}$.

For this, it clearly suffices to prove that $f(g) \in U^{H\cap K}$ for every $g \in G$. So fix $g \in G$. Let $k \in H \cap K$. Then, $k \cdot f(g) = f(kg)$ (since f is $\mathbb{C}H$-linear and $k \in H$) and $f(g) = f(kg)$ (since $k \in K$, so that (13.108.7) yields $g - kg \in \ker(\mathbb{C}[\pi]) \subset \ker f$ and thus $f(g - kg) = 0$). Hence, $k \cdot f(g) = f(kg) = f(g)$. Since this has been proven for all $k \in H \cap K$, we thus have $f(g) \in U^{H\cap K}$, qed.

[789] This is straightforward to see (everything in sight is $\mathbb{C}H$-linear).

[790] In fact, defining the inverse is very easy (just send every map $g \in \operatorname{Hom}_{\mathbb{C}[H/(H\cap K)]}\left(\mathbb{C}[G/K], U^{H\cap K}\right)$ to the composition $\mathbb{C}G \xrightarrow{\mathbb{C}[\pi]} \mathbb{C}[G/K] \xrightarrow{g} U^{H\cap K} \xrightarrow{\text{inclusion}} U$). Checking that these maps are mutually inverse is also straightforward.

[791] Indeed, it is easier to check that its inverse is $\mathbb{C}[G/K]$-linear (this can be proven by straightforward computations).

13.109. **Solution to Exercise 4.1.11.** *Solution to Exercise 4.1.11.* In the following, we will write g for the element t_g of $\mathbb{C}G$ whenever g is an element of G. This is a relatively common abuse of notation, and it is harmless because the map $G \to \mathbb{C}G,\ g \mapsto t_g$ is an injective homomorphism of multiplicative monoids (so $t_{gh} = t_g t_h$ and $t_1 = 1$, which means that we won't run into ambiguities denoting t_g by g) and because every $\mathbb{C}G$-module M, every $m \in M$ and every $g \in G$ satisfy $gm = t_g m$. We will do the same abuse of notation for elements of H and of K.

Inflation does not change the underlying $\mathbb{C}$-vector space of a representation. Thus, $\operatorname{Infl}_{G/K}^{G} \operatorname{Ind}_{H/K}^{G/K} V = \operatorname{Ind}_{H/K}^{G/K} V$ as $\mathbb{C}$-vector spaces. For the same reason, $\operatorname{Infl}_{H/K}^{H} V = V$ as $\mathbb{C}$-vector spaces.

Let π_G be the canonical projection map $G \to G/K$. This gives rise to a surjective $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\pi_G] : \mathbb{C}G \to \mathbb{C}[G/K]$ (which sends every $g \in G$ to $\pi_G(g)$). We now define a $\mathbb{C}$-linear map

$$\beta : \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^{H} V \to \mathbb{C}[G/K] \otimes_{\mathbb{C}[H/K]} V, \\ s \otimes_{\mathbb{C}H} v \mapsto (\mathbb{C}[\pi_G])(s) \otimes_{\mathbb{C}[H/K]} v.$$

This is easily seen to be well-defined (using the universal property of the tensor product and the observation that every $t \in \mathbb{C}H$ satisfies $(\mathbb{C}[\pi_G])(t) \in \mathbb{C}[H/K]$).

We also want to define a map α in the opposite direction, but this will require some more work. First, for every $g \in G$, we define a $\mathbb{C}$-linear map

$$\mathbf{a}_g : V \to \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^{H} V, \\ v \mapsto g \otimes_{\mathbb{C}H} v.$$

It is easily seen that if g_1 and g_2 are two elements of G satisfying $\pi_G(g_1) = \pi_G(g_2)$, then $\mathbf{a}_{g_1} = \mathbf{a}_{g_2}$ [792]. In other words, the map $\mathbf{a}_g$ depends only on $\pi_G(g)$ rather than on g itself. Thus, we can define a $\mathbb{C}$-linear map $\widetilde{\mathbf{a}}_p : V \to \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^{H} V$ for every $p \in G/K$ by choosing any $g \in G$ satisfying $\pi_G(g) = p$, and then setting $\widetilde{\mathbf{a}}_p = \mathbf{a}_g$; the resulting map $\widetilde{\mathbf{a}}_p$ does not depend on the choice of g.

Hence, we have defined a $\mathbb{C}$-linear map $\widetilde{\mathbf{a}}_p : V \to \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^{H} V$ for every $p \in G/K$. In other words, we have defined an element $\widetilde{\mathbf{a}}_p$ of $\operatorname{Hom}_{\mathbb{C}}\left(V, \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^{H} V\right)$ for every $p \in G/K$. Hence, we can define a $\mathbb{C}$-linear map

$$\mathbf{A} : \mathbb{C}[G/K] \to \operatorname{Hom}_{\mathbb{C}}\left(V, \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^{H} V\right), \\ p \mapsto \widetilde{\mathbf{a}}_p \qquad \text{for every } p \in G/K$$

(because in order to define a $\mathbb{C}$-linear map from the $\mathbb{C}$-vector space $\mathbb{C}[G/K]$, it is enough to assign its values on the basis G/K). Using this map $\mathbf{A}$, we can now define a $\mathbb{C}$-linear map

$$\alpha : \mathbb{C}[G/K] \otimes_{\mathbb{C}[H/K]} V \to \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^{H} V, \\ s \otimes_{\mathbb{C}[H/K]} v \mapsto (\mathbf{A}(s))(v).$$

[792] Indeed, let g_1 and g_2 be two elements of G satisfying $\pi_G(g_1) = \pi_G(g_2)$. Then, $g_1 \in g_2 K$, so that there exists some $k \in K$ such that $g_1 = g_2 k$. Consider this k. Then, every $v \in V$ satisfies

$$\begin{aligned} \mathbf{a}_{g_1}(v) &= \underbrace{g_1}_{=g_2 k} \otimes_{\mathbb{C}H} v \qquad (\text{by the definition of } \mathbf{a}_{g_1}) \\ &= g_2 k \otimes_{\mathbb{C}H} v = g_2 \otimes_{\mathbb{C}H} \underbrace{kv}_{\substack{=v \\ (\text{since } k \in K \text{ acts trivially} \\ \text{on } \operatorname{Infl}_{H/K}^{H} V)}} \qquad (\text{since } k \text{ lies in } K \subset H, \text{ and thus can be moved past the } \otimes_{\mathbb{C}H} \text{ sign}) \\ &= g_2 \otimes_{\mathbb{C}H} v = \mathbf{a}_{g_2}(v) \qquad (\text{by the definition of } \mathbf{a}_{g_2}). \end{aligned}$$

Thus, $\mathbf{a}_{g_1} = \mathbf{a}_{g_2}$, qed.

It is again easy to check that this is well-defined[793]. It is straightforward to show that $\alpha \circ \beta = \operatorname{id}$ (indeed, this only needs to be proven on tensors of the form $g \otimes_{\mathbb{C}H} v$ for $g \in G$ and $v \in \operatorname{Infl}_{H/K}^H V$, because the $\mathbb{C}$-vector space $\mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^H V$ is spanned by such tensors; but on such tensors it is very easy to check) and $\beta \circ \alpha = \operatorname{id}$ (using a similar argument). Thus, the maps α and β are mutually inverse, and therefore β is invertible. But we can regard β as a map from $\operatorname{Ind}_H^G \operatorname{Infl}_{H/K}^H V$ to $\operatorname{Infl}_{G/K}^G \operatorname{Ind}_{H/K}^{G/K} V$ (since $\operatorname{Ind}_H^G \operatorname{Infl}_{H/K}^H V = \mathbb{C}G \otimes_{\mathbb{C}H} \operatorname{Infl}_{H/K}^H V$ and $\operatorname{Infl}_{G/K}^G \operatorname{Ind}_{H/K}^{G/K} V = \operatorname{Ind}_{H/K}^{G/K} V = \mathbb{C}[G/K] \otimes_{\mathbb{C}[H/K]} V$ as $\mathbb{C}$-vector spaces), and it is easy to verify that β becomes a $\mathbb{C}G$-module homomorphism when regarded this way. Thus, β is an invertible $\mathbb{C}G$-module homomorphism from $\operatorname{Ind}_H^G \operatorname{Infl}_{H/K}^H V$ to $\operatorname{Infl}_{G/K}^G \operatorname{Ind}_{H/K}^{G/K} V$, hence a $\mathbb{C}G$-module isomorphism. Thus, such an isomorphism exists, i.e., we have $\operatorname{Infl}_{G/K}^G \operatorname{Ind}_{H/K}^{G/K} V \cong \operatorname{Ind}_H^G \operatorname{Infl}_{H/K}^H V$ as $\mathbb{C}G$-modules. This solves Exercise 4.1.11.

13.110. **Solution to Exercise 4.1.12.** *Solution to Exercise 4.1.12.* (a) It is clearly enough to show that $g(v-kv) \in I_{V,K}$ for all $g \in G$, $k \in K$ and $v \in V$. But if $g \in G$, $k \in K$ and $v \in V$, then gk has the form $gk = k'g$ for some $k' \in K$ (since $K \triangleleft G$), and thus we have $g(v-kv) = gv - \underbrace{gk}_{=k'g} v = gv - k'gv \in I_{V,K}$ (by the definition of $I_{V,K}$, since $k' \in K$ and $gv \in V$). Hence, part (a) of the exercise is solved.

(b) For every $v \in V$, let $\overline{v}$ denote the projection of v onto the quotient space $V/I_{V,K} = V_K$.

We can define a map $\Phi : V^K \to V_K$ by sending every $v \in V^K$ to $\overline{v} \in V_K$. This map Φ is easily seen to be a $\mathbb{C}G$-module homomorphism $\operatorname{Infl}_{G/K}^G \left(V^K\right) \to V_K$. If we can show that Φ is also bijective, then it will follow that Φ is a $\mathbb{C}G$-module isomorphism $\operatorname{Infl}_{G/K}^G \left(V^K\right) \to V_K$, whence part (b) of the exercise will be solved. Hence, all that remains to be done is proving that Φ is bijective.

Let us construct an inverse map to Φ. First, let us notice that every $v \in V$ satisfies

$$\frac{1}{|K|} \sum_{j \in K} jv \in V^K.$$

[794] Thus, we can define a map $\psi : V \to V^K$ by sending every $v \in V$ to $\frac{1}{|K|} \sum_{j \in K} jv$. This map ψ is $\mathbb{C}$-linear and vanishes on $I_{V,K}$ [795]. Hence, the map ψ factors through the quotient $V/I_{V,K} = V_K$. Let us denote

[793] *Proof.* In order to prove this well-definedness, we have to check that $(\mathbf{A}(s))(v)$ depends $\mathbb{C}[H/K]$-bilinearly on (s,v). It is very easy to see that $(\mathbf{A}(s))(v)$ depends $\mathbb{C}$-bilinearly on (s,v); therefore, it only remains to prove that $(\mathbf{A}(st))(v) = (\mathbf{A}(s))(tv)$ for all $s \in \mathbb{C}[G/K]$, $t \in \mathbb{C}[H/K]$ and $v \in V$. So let $s \in \mathbb{C}[G/K]$, $t \in \mathbb{C}[H/K]$ and $v \in V$ be arbitrary. We want to prove that $(\mathbf{A}(st))(v) = (\mathbf{A}(s))(tv)$. Since both sides of this equality are $\mathbb{C}$-linear in s, we can WLOG assume that s belongs to the basis G/K of $\mathbb{C}[G/K]$. Assume this, and pick $g \in G$ such that $s = \pi_G(g)$. (This g exists since π_G is surjective.)

Similarly, we can WLOG assume that t belongs to the basis H/K of $\mathbb{C}[H/K]$. Assume this and pick $h \in H$ such that $t = \pi_G(h)$. (This t exists since $H/K = \pi_G(H)$.) Since $s = \pi_G(g)$ and $t = \pi_G(h)$, we have $st = \pi_G(g) \cdot \pi_G(h) = \pi_G(gh)$ (as π_G is a group homomorphism). Notice that $\underbrace{t}_{=\pi_G(h)} v = \pi_G(h) v = hv$ (because the action of H on $\operatorname{Infl}_{H/K}^H V$ factors through π_G).

Now, the definition of $\mathbf{A}(st)$ yields $\mathbf{A}(st) = \widetilde{\mathbf{a}}_{st} = \mathbf{a}_{gh}$ (by the definition of $\widetilde{\mathbf{a}}_{st}$, since $st = \pi_G(gh)$). Similarly, $\mathbf{A}(s) = \mathbf{a}_g$. Now, comparing $\underbrace{(\mathbf{A}(st))}_{=\mathbf{a}_{gh}}(v) = \mathbf{a}_{gh}(v) = gh \otimes_{\mathbb{C}H} v = g \otimes_{\mathbb{C}H} hv$ (since h belongs to $\mathbb{C}H$ and thus can be moved past the $\otimes_{\mathbb{C}H}$ sign) with $\underbrace{(\mathbf{A}(s))}_{=\mathbf{a}_g}\left(\underbrace{tv}_{=hv}\right) = \mathbf{a}_g(hv) = g \otimes_{\mathbb{C}H} hv$, we obtain $(\mathbf{A}(st))(v) = (\mathbf{A}(s))(tv)$, which is precisely what we needed to prove.

[794] *Proof.* Let $v \in V$. Let $j \in K$. Then, the map $K \to K,\ s \mapsto js$ is a bijection (since $j \in K$ and since K is a group). Now,

$$j \cdot \left(\frac{1}{|K|} \sum_{s \in K} sv \right) = \frac{1}{|K|} \sum_{s \in K} jsv = \frac{1}{|K|} \sum_{s \in K} sv$$

(here, we have substituted s for js in the sum, because the map $K \to K,\ s \mapsto js$ is a bijection). Now, forget that we fixed j. We thus have shown that $j \cdot \left(\frac{1}{|K|} \sum_{s \in K} sv \right) = \frac{1}{|K|} \sum_{s \in K} sv$ for every $j \in K$. Hence, $\frac{1}{|K|} \sum_{s \in K} sv \in V^K$, qed.

[795] *Proof.* We want to show that ψ vanishes on $I_{V,K}$. In order to do so, we only need to check that $\psi(v-kv) = 0$ for all $k \in K$ and $v \in V$ (since $I_{V,K}$ is spanned by all $v - kv$ with $k \in K$ and $v \in V$). But this follows from the fact that all $k \in K$

the resulting $\mathbb{C}$-linear map $V_K \to V^K$ by Ψ. We are now going to show that the maps Φ and Ψ are mutually inverse.

We have $\Phi \circ \Psi = \mathrm{id}$ [796] and $\Psi \circ \Phi = \mathrm{id}$ [797]. Hence, the maps Φ and Ψ are mutually inverse. It follows that Φ is bijective, and so the solution is complete.

13.111. **Solution to Exercise 4.1.14.** *Solution to Exercise 4.1.14.* In the following, we will use the following convention: Whenever K is a group, and k is an element of K, we shall write k for the element t_k of $\mathbb{C}K$. This is a relatively common abuse of notation, and it is harmless because the map $K \to \mathbb{C}K,\ k \mapsto t_k$ is an injective homomorphism of multiplicative monoids (so $t_{gh} = t_g t_h$ and $t_1 = 1$, which means that we won't run into ambiguities denoting t_k by k) and because every $\mathbb{C}K$-module M, every $m \in M$ and every $k \in K$ satisfy $km = t_k m$.

and $v \in V$ satisfy

$$\begin{aligned}
\psi(v - kv) &= \frac{1}{|K|} \sum_{j \in K} \underbrace{j(v - kv)}_{= jv - jkv} \qquad \text{(by the definition of } \psi\text{)} \\
&= \frac{1}{|K|} \sum_{j \in K} (jv - jkv) = \frac{1}{|K|} \sum_{j \in K} jv - \frac{1}{|K|} \sum_{j \in K} jkv = \frac{1}{|K|} \sum_{j \in K} jv - \frac{1}{|K|} \sum_{j \in K} jv \\
&\qquad \left(\begin{array}{c} \text{here, we have substituted } j \text{ for } jk \text{ in the second sum, since the map } K \to K,\ j \mapsto jk \\ \text{is a bijection (because } k \in K \text{ and because } K \text{ is a group)} \end{array} \right) \\
&= 0.
\end{aligned}$$

[796] *Proof.* Let $w \in V_K$. Then, there exists some $v \in V$ such that $w = \overline{v}$. Consider this v. Since Ψ was defined as a quotient of the map ψ, we have $\Psi(\overline{v}) = \psi(v)$. Now,

$$\begin{aligned}
(\Phi \circ \Psi)\left(\underbrace{w}_{=\overline{v}}\right) &= (\Phi \circ \Psi)(\overline{v}) = \Phi\left(\underbrace{\Psi(\overline{v})}_{=\psi(v)}\right) = \Phi\left(\underbrace{\psi(v)}_{\substack{= \frac{1}{|K|}\sum_{j \in K} jv \\ \text{(by the definition of } \psi\text{)}}}\right) = \Phi\left(\frac{1}{|K|} \sum_{j \in K} jv\right) \\
&= \overline{\frac{1}{|K|} \sum_{j \in K} jv} \qquad \text{(by the definition of } \Phi\text{)} \\
&= \frac{1}{|K|} \sum_{j \in K} \underbrace{\overline{jv}}_{\substack{= \overline{v} \\ \text{(since } v - jv \in I_{V,K} \\ \text{(because } j \in K\text{))}}} = \frac{1}{|K|} \underbrace{\sum_{j \in K} \overline{v}}_{= |K| \cdot \overline{v}} = \frac{1}{|K|} |K| \cdot \overline{v} = \overline{v} = w.
\end{aligned}$$

Thus we have shown that $(\Phi \circ \Psi)(w) = w$ for every $w \in V_K$. In other words, $\Phi \circ \Psi = \mathrm{id}$, qed.

[797] *Proof.* For every $v \in V^K$, we have

$$\begin{aligned}
(\Psi \circ \Phi)(v) &= \Psi\left(\underbrace{\Phi(v)}_{\substack{= \overline{v} \\ \text{(by the definition of } \Phi\text{)}}}\right) = \Psi(\overline{v}) = \psi(v) \\
&\qquad \text{(since } \Psi \text{ was defined as the quotient of the map } \psi\text{)} \\
&= \frac{1}{|K|} \sum_{j \in K} \underbrace{jv}_{\substack{= v \\ \text{(since } v \in V^K \text{ and } j \in K\text{)}}} \qquad \text{(by the definition of } \psi\text{)} \\
&= \frac{1}{|K|} \underbrace{\sum_{j \in K} v}_{= |K| \cdot v} = \frac{1}{|K|} |K| \cdot v = v.
\end{aligned}$$

Thus, $\Psi \circ \Phi = \mathrm{id}$, qed.

Let us first notice a trivial fact: If K is a finite group, and if $f : K \to \mathbb{C}$ is any function, then we have the following equivalence:

$$\begin{aligned} & \left(f \in R_{\mathbb{C}}\left(K\right)\right) \\ \Longleftrightarrow\ & \left(f \text{ is a class function on } K\right) \\ & \qquad \left(\begin{array}{c} \text{since } R_{\mathbb{C}}\left(K\right) \text{ is defined to be} \\ \text{the set of all class functions on } K \end{array}\right) \\ \Longleftrightarrow\ & \left(f \text{ is constant on } K\text{-conjugacy classes}\right) \\ & \qquad \left(\begin{array}{c} \text{since a class function on } K \text{ is defined to mean a function} \\ K \to \mathbb{C} \text{ which is constant on } K\text{-conjugacy classes} \end{array}\right) \\ \Longleftrightarrow\ & \left(\text{any two conjugate elements } k \text{ and } k' \text{ of } K \text{ satisfy } f\left(k\right) = f\left(k'\right)\right). \end{aligned} \tag{13.111.1}$$

(a) Let $f \in R_{\mathbb{C}}\left(H\right)$.

We can apply (13.111.1) to $K = H$. As a consequence, we obtain the following equivalence:

$$\begin{aligned} & \left(f \in R_{\mathbb{C}}\left(H\right)\right) \\ \Longleftrightarrow\ & \left(\text{any two conjugate elements } k \text{ and } k' \text{ of } H \text{ satisfy } f\left(k\right) = f\left(k'\right)\right). \end{aligned}$$

Hence,

$$\text{any two conjugate elements } k \text{ and } k' \text{ of } H \text{ satisfy } f\left(k\right) = f\left(k'\right) \tag{13.111.2}$$

(because we know that $f \in R_{\mathbb{C}}\left(H\right)$).

Now, let g and g' be two conjugate elements of G. Then, there exists a $p \in G$ such that $g' = pgp^{-1}$ (since g and g' are conjugate). Consider this p.

Applying the map $\operatorname{Ind}_\rho f$ to both sides of the equality $g' = pgp^{-1}$, we obtain

$$(\operatorname{Ind}_\rho f)(g') = (\operatorname{Ind}_\rho f)\left(pgp^{-1}\right) = \frac{1}{|H|} \underbrace{\sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=pgp^{-1}}}}_{=\sum_{h\in H}\sum_{\substack{k\in G;\\ k\rho(h)k^{-1}=pgp^{-1}}}} f(h)$$

$$\left(\text{by the definition of } \operatorname{Ind}_\rho f\right)$$

$$= \frac{1}{|H|}\sum_{h\in H} \underbrace{\sum_{\substack{k\in G;\\ k\rho(h)k^{-1}=pgp^{-1}}} f(h)}_{\substack{=\sum_{\substack{k\in G;\\ pk\rho(h)(pk)^{-1}=pgp^{-1}}} f(h)\\ \text{(here, we have substituted } pk \text{ for } k \text{ in the sum,}\\ \text{since the map } G\to G,\ k\mapsto pk \text{ is a bijection)}}}$$

$$= \frac{1}{|H|}\sum_{h\in H} \underbrace{\sum_{\substack{k\in G;\\ pk\rho(h)(pk)^{-1}=pgp^{-1}}}}_{\substack{=\sum_{\substack{k\in G;\\ pk\rho(h)k^{-1}p^{-1}=pgp^{-1}}}\\ \text{(since } (pk)^{-1}=k^{-1}p^{-1}\text{)}}} f(h) = \frac{1}{|H|}\sum_{h\in H} \underbrace{\sum_{\substack{k\in G;\\ pk\rho(h)k^{-1}p^{-1}=pgp^{-1}}}}_{\substack{=\sum_{\substack{k\in G;\\ pk\rho(h)k^{-1}=pg}}\\ \text{(since } pk\rho(h)k^{-1}p^{-1}=pgp^{-1} \text{ is}\\ \text{equivalent to } pk\rho(h)k^{-1}=pg\text{)}}} f(h)$$

$$= \frac{1}{|H|}\sum_{h\in H} \underbrace{\sum_{\substack{k\in G;\\ pk\rho(h)k^{-1}=pg}}}_{\substack{=\sum_{\substack{k\in G;\\ k\rho(h)k^{-1}=g}}\\ \text{(since } pk\rho(h)k^{-1}=pg \text{ is}\\ \text{equivalent to } k\rho(h)k^{-1}=g\text{)}}} f(h) = \frac{1}{|H|} \underbrace{\sum_{h\in H}\sum_{\substack{k\in G;\\ k\rho(h)k^{-1}=g}}}_{=\sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}}} f(h)$$

$$= \frac{1}{|H|}\sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}} f(h) = (\operatorname{Ind}_\rho f)(g)$$

(since the definition of $\operatorname{Ind}_\rho f$ yields $(\operatorname{Ind}_\rho f)(g) = \frac{1}{|H|}\sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}} f(h)$).

Let us now forget that we fixed g and g'. We thus have shown that any two conjugate elements g and g' of G satisfy $(\operatorname{Ind}_\rho f)(g) = (\operatorname{Ind}_\rho f)(g')$. Renaming g and g' as k and k' in this statement, we obtain the following: Any two conjugate elements k and k' of G satisfy $(\operatorname{Ind}_\rho f)(k) = (\operatorname{Ind}_\rho f)(k')$.

But (13.111.1) (applied to G and $\operatorname{Ind}_\rho f$ instead of K and f) yields the following equivalence:

$$\begin{aligned} &\left(\operatorname{Ind}_\rho f \in R_{\mathbb{C}}(G)\right)\\ \iff &\left(\text{any two conjugate elements } k \text{ and } k' \text{ of } G \text{ satisfy } (\operatorname{Ind}_\rho f)(k) = (\operatorname{Ind}_\rho f)(k')\right). \end{aligned}$$

Thus, $\operatorname{Ind}_\rho f \in R_{\mathbb{C}}(G)$ (because we know that any two conjugate elements k and k' of G satisfy $(\operatorname{Ind}_\rho f)(k) = (\operatorname{Ind}_\rho f)(k')$). This solves Exercise 4.1.14(a).

(b) Let us first introduce an elementary (but apocryphal) notion from linear algebra: the notion of *finite dual generating systems.*

Definition 13.111.1. Let $\mathbb{K}$ be a commutative ring. Let V be a $\mathbb{K}$-module. A *finite dual generating system* for V means a triple $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$, where

- I is a finite set;
- $(a_i)_{i\in I}$ is a family of elements of V;

- $(f_i)_{i\in I}$ is a family of elements of V^* (where V^* means $\operatorname{Hom}_{\mathbb{K}}(V,\mathbb{K})$)

such that every $v \in V$ satisfies $v = \sum\limits_{i\in I} f_i(v)\, a_i$.

In the following, we shall only use finite dual generating systems in the case when $\mathbb{K}$ is a field; nevertheless, they are more useful in the general case.

The first question one might ask about finite dual generating systems for V is when they exist. The answer is very simple when $\mathbb{K}$ is a field:

Proposition 13.111.2. *Let $\mathbb{K}$ be a field. Let V be a $\mathbb{K}$-vector space. Then, a finite dual generating system for V exists if and only if the vector space V is finite-dimensional.*

Proof of Proposition 13.111.2. Proposition 13.111.2 is an "if and only if" statement. Hence, in order to prove Proposition 13.111.2, it is sufficient to verify the following two claims:

> *Claim 1:* If a finite dual generating system for V exists, then the vector space V is finite-dimensional.
>
> *Claim 2:* If the vector space V is finite-dimensional, then a finite dual generating system for V exists.

Let us now prove these two claims.

Proof of Claim 1. Assume that a finite dual generating system for V exists. Let $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$ be such a finite dual generating system for V.

We know that I is a finite set, that $(a_i)_{i\in I}$ is a family of elements of V, and that every $v \in V$ satisfies $v = \sum\limits_{i\in I} f_i(v)\, a_i$. (Indeed, this is part of what it means for $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$ to be a finite dual generating system for V.)

Now, every $v \in V$ satisfies $v = \sum\limits_{i\in I} \underbrace{f_i(v)}_{\in\mathbb{K}} a_i \in \sum\limits_{i\in I} \mathbb{K}a_i$. Thus, $V \subset \sum\limits_{i\in I} \mathbb{K}a_i$. Combined with the (obvious) inclusion $\sum\limits_{i\in I} \mathbb{K}a_i \subset V$, this yields $V = \sum\limits_{i\in I} \mathbb{K}a_i$. But the vector space $\sum\limits_{i\in I} \mathbb{K}a_i$ is finite-dimensional (since I is a finite set). In other words, the vector space V is finite-dimensional (since $V = \sum\limits_{i\in I} \mathbb{K}a_i$). This proves Claim 1.

Proof of Claim 2. Assume that V is a finite-dimensional vector space. Then, V has a finite basis. Let $(e_i)_{i\in I}$ be such a basis. Thus, I is a finite set, and $(e_i)_{i\in I}$ is a basis of the $\mathbb{K}$-vector space V. Let $(e_i^*)_{i\in I}$ be the basis of V^* dual to the basis $(e_i)_{i\in I}$ of V. (This is well-defined, since V is finite-dimensional.)

We know that $(e_i^*)_{i\in I}$ is the basis of V^* dual to the basis $(e_i)_{i\in I}$ of V. Thus,

$$e_i^* \left(\sum_{j\in I} \lambda_j e_j \right) = \lambda_i \qquad \text{for all } i \in I \text{ and } (\lambda_j)_{j\in I} \in \mathbb{K}^I. \tag{13.111.3}$$

(Indeed, this is one of the ways to define a dual basis.)

Now, every $v \in V$ satisfies $v = \sum\limits_{i\in I} e_i^*(v)\, e_i$ [798].

So we know that $\left(I, (e_i)_{i\in I}, (e_i^*)_{i\in I}\right)$ is a triple such that

- I is a finite set;
- $(e_i)_{i\in I}$ is a family of elements of V;

[798] *Proof.* Let $v \in V$. Then, we can write v in the form $v = \sum\limits_{i\in I} \lambda_i e_i$ for some family $(\lambda_i)_{i\in I} \in \mathbb{K}^I$ (since $(e_i)_{i\in I}$ is a basis of V). Consider this family $(\lambda_i)_{i\in I}$. Now, $v = \sum\limits_{i\in I} \lambda_i e_i = \sum\limits_{j\in I} \lambda_j e_j$ (here, we have renamed the summation index i as j in the sum). For each $i \in I$, we now have

$$e_i^* \left(\underbrace{v}_{= \sum\limits_{j\in I} \lambda_j e_j} \right) = e_i^* \left(\sum_{j\in I} \lambda_j e_j \right) = \lambda_i \qquad \text{(by (13.111.3))}.$$

Thus, $\sum\limits_{i\in I} \underbrace{e_i^*(v)}_{=\lambda_i} e_i = \sum\limits_{i\in I} \lambda_i e_i$. Compared with $v = \sum\limits_{i\in I} \lambda_i e_i$, this yields $v = \sum\limits_{i\in I} e_i^*(v)\, e_i$, qed.

- $\left(e_i^*\right)_{i\in I}$ is a family of elements of V^* (where V^* means $\operatorname{Hom}_{\mathbb{K}}(V,\mathbb{K})$)

such that every $v \in V$ satisfies $v = \sum\limits_{i\in I} e_i^*(v)\, e_i$. In other words, $\left(I, (e_i)_{i\in I}, \left(e_i^*\right)_{i\in I}\right)$ is a finite dual generating system for V (by the definition of a "finite dual generating system"). Thus, a finite dual generating system for V exists (namely, $\left(I, (e_i)_{i\in I}, \left(e_i^*\right)_{i\in I}\right)$). This proves Claim 2.

Now, both Claim 1 and Claim 2 are proven. Hence, the proof of Proposition 13.111.2 is complete. □

[*Remark:* The notion of finite dual generating system for V is more versatile than the notion of a finite basis of V. One difference between these notions is that all bases of V have the same size, while the set I in a finite dual generating system $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$ of V can have any (finite) size $\geq \dim V$. Another difference manifests itself in the general setting when $\mathbb{K}$ is a commutative ring, not necessarily a field. In this generality, a finite basis of V exists if and only if V is a finite free $\mathbb{K}$-module (this is the definition of a finite free $\mathbb{K}$-module), whereas a finite dual generating system for V exists if and only if V is a finitely generated projective $\mathbb{K}$-module. Projective $\mathbb{K}$-modules are a more frequent occurrence in commutative algebra than free $\mathbb{K}$-modules, and in the absence of a finite basis, a finite dual generating system is the thing that comes closest to allowing "computing in a basis".]

One significant application of finite dual generating systems is computing traces of endomorphisms:

Proposition 13.111.3. *Let $\mathbb{K}$ be a field. Let V be a finite-dimensional $\mathbb{K}$-vector space. Let $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$ be a finite dual generating system for V. Let $T : V \to V$ be a $\mathbb{K}$-linear map. Then,*

$$\operatorname{trace} T = \sum_{i\in I} f_i(Ta_i).$$

Proposition 13.111.3 can be easily proven directly, but let us take a slight detour and derive it from the following more general fact:

Proposition 13.111.4. *Let $\mathbb{K}$ be a commutative ring. Let V be a $\mathbb{K}$-module. Let $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$ be a finite dual generating system for V. Let $\left(J, (b_j)_{j\in J}, (g_j)_{j\in J}\right)$ be a further finite dual generating system for V. Let $T : V \to V$ be a $\mathbb{K}$-linear map. Then,*

$$\sum_{i\in I} f_i(Ta_i) = \sum_{j\in J} g_j(Tb_j).$$

Proof of Proposition 13.111.4. We know that $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$ is a finite dual generating system for V. In other words, $\left(I, (a_i)_{i\in I}, (f_i)_{i\in I}\right)$ is a triple such that

- I is a finite set;
- $(a_i)_{i\in I}$ is a family of elements of V;
- $(f_i)_{i\in I}$ is a family of elements of V^* (where V^* means $\operatorname{Hom}_{\mathbb{K}}(V,\mathbb{K})$)

such that every $v \in V$ satisfies

$$v = \sum_{i\in I} f_i(v)\, a_i. \tag{13.111.4}$$

We know that $\left(J, (b_j)_{j\in J}, (g_j)_{j\in J}\right)$ is a finite dual generating system for V. In other words, $\left(J, (b_j)_{j\in J}, (g_j)_{j\in J}\right)$ is a triple such that

- J is a finite set;
- $(b_j)_{j\in J}$ is a family of elements of V;
- $(g_j)_{j\in J}$ is a family of elements of V^* (where V^* means $\operatorname{Hom}_{\mathbb{K}}(V,\mathbb{K})$)

such that every $v \in V$ satisfies

$$v = \sum_{j\in J} g_j(v)\, b_j. \tag{13.111.5}$$

Now,

$$\sum_{i\in I} f_i \left(\underbrace{Ta_i}_{\substack{=\sum\limits_{j\in J} g_j(Ta_i) b_j \\ \text{(by (13.111.5), applied} \\ \text{to } v=Ta_i)}} \right) = \sum_{i\in I} \underbrace{f_i\left(\sum_{j\in J} g_j\left(Ta_i\right) b_j\right)}_{\substack{=\sum\limits_{j\in J} g_j(Ta_i) f_i(b_j) \\ \text{(since the map } f_i \text{ is } \mathbb{K}\text{-linear)}}} = \underbrace{\sum_{i\in I}\sum_{j\in J}}_{=\sum_{j\in J}\sum_{i\in I}} \underbrace{g_j\left(Ta_i\right) f_i\left(b_j\right)}_{=f_i(b_j) g_j(Ta_i)}$$
$$= \sum_{j\in J}\sum_{i\in I} f_i\left(b_j\right) g_j\left(Ta_i\right).$$

Compared with

$$\sum_{j\in J} g_j \left(T \underbrace{b_j}_{\substack{=\sum\limits_{i\in I} f_i(b_j) a_i \\ \text{(by (13.111.4), applied} \\ \text{to } v=b_j)}} \right) = \sum_{j\in J} g_j \left(\underbrace{T \sum_{i\in I} f_i\left(b_j\right) a_i}_{\substack{=\sum_{i\in I} f_i(b_j) Ta_i \\ \text{(since the map } T \text{ is } \mathbb{K}\text{-linear)}}} \right) = \sum_{j\in J} \underbrace{g_j\left(\sum_{i\in I} f_i\left(b_j\right) Ta_i\right)}_{\substack{=\sum\limits_{i\in I} f_i(b_j) g_j(Ta_i) \\ \text{(since the map } g_j \text{ is } \mathbb{K}\text{-linear)}}}$$
$$= \sum_{j\in J}\sum_{i\in I} f_i\left(b_j\right) g_j\left(Ta_i\right),$$

this yields $\sum_{i\in I} f_i\left(Ta_i\right) = \sum_{j\in J} g_j\left(Tb_j\right)$. This proves Proposition 13.111.4. □

Proof of Proposition 13.111.3. The vector space V has a finite basis (since it is finite-dimensional). Let $\left(e_1, e_2, \ldots, e_n\right)$ be such a basis. Let $\left(m_{i,j}\right)_{1\leq i,j\leq n} \in \mathbb{K}^{n\times n}$ be the matrix which represents the map $T : V \to V$ with respect to this basis $\left(e_1, e_2, \ldots, e_n\right)$ of V. Then,

$$Te_j = \sum_{i=1}^{n} m_{i,j} e_i \qquad \text{for every } j \in \{1, 2, \ldots, n\} \tag{13.111.6}$$

(due to the definition of "the matrix which represents the map $T : V \to V$ with respect to this basis $\left(e_1, e_2, \ldots, e_n\right)$ of V").

Let $\left(e_1^*, e_2^*, \ldots, e_n^*\right)$ be the basis of V^* dual to the basis $\left(e_1, e_2, \ldots, e_n\right)$ of V. (This is well-defined, since V is finite-dimensional.) Thus,

$$e_k^*\left(\sum_{i=1}^{n} \lambda_i e_i\right) = \lambda_k \qquad \text{for all } k \in \{1, 2, \ldots, n\} \text{ and } \left(\lambda_1, \lambda_2, \ldots, \lambda_n\right) \in \mathbb{K}^n. \tag{13.111.7}$$

(This follows immediately from the definition of a "dual basis".) Now, every $k \in \{1, 2, \ldots, n\}$ and $j \in \{1, 2, \ldots, n\}$ satisfy

$$e_k^*\left(Te_j\right) = m_{k,j}. \tag{13.111.8}$$

[799] Now, every $v \in V$ satisfies $v = \sum\limits_{i\in\{1,2,\ldots,n\}} e_i^*\left(v\right) e_i$ [800].

So we know that $\left(\{1, 2, \ldots, n\}, \left(e_i\right)_{i\in\{1,2,\ldots,n\}}, \left(e_i^*\right)_{i\in\{1,2,\ldots,n\}}\right)$ is a triple such that

[799] *Proof of (13.111.8):* Fix $k \in \{1, 2, \ldots, n\}$ and $j \in \{1, 2, \ldots, n\}$. Applying the map e_k^* to both sides of (13.111.6), we obtain

$$e_k^*\left(Te_j\right) = e_k^*\left(\sum_{i=1}^{n} m_{i,j} e_i\right) = m_{k,j} \qquad \text{(by (13.111.7), applied to } \lambda_i = m_{i,j}\text{)}.$$

This proves (13.111.8).

[800] *Proof.* Let $v \in V$. Then, we can write v in the form $v = \sum\limits_{i=1}^{n} \lambda_i e_i$ for some n-tuple $\left(\lambda_1, \lambda_2, \ldots, \lambda_n\right) \in \mathbb{K}^n$ (since $\left(e_1, e_2, \ldots, e_n\right)$ is a basis of V). Consider this n-tuple $\left(\lambda_1, \lambda_2, \ldots, \lambda_n\right)$. Now, $v = \sum\limits_{i=1}^{n} \lambda_i e_i$. Hence, for each $k \in \{1, 2, \ldots, n\}$, we

- $\{1,2,\ldots,n\}$ is a finite set;
- $(e_i)_{i\in\{1,2,\ldots,n\}}$ is a family of elements of V;
- $(e_i^*)_{i\in\{1,2,\ldots,n\}}$ is a family of elements of V^* (where V^* means $\operatorname{Hom}_{\mathbb{K}}(V,\mathbb{K})$)

such that every $v\in V$ satisfies $v=\sum\limits_{i\in\{1,2,\ldots,n\}} e_i^*(v)\,e_i$. In other words, $\left(\{1,2,\ldots,n\},(e_i)_{i\in\{1,2,\ldots,n\}},(e_i^*)_{i\in\{1,2,\ldots,n\}}\right)$ is a finite dual generating system for V. Therefore, Proposition 13.111.4 (applied to $\left(J,(b_j)_{j\in J},(g_j)_{j\in J}\right)=\left(\{1,2,\ldots,n\},(e_i)_{i\in\{1,2,\ldots,n\}},(e_i^*)_{i\in\{1,2,\ldots,n\}}\right)$) yields

$$\begin{aligned}\sum_{i\in I} f_i(Ta_i) &= \underbrace{\sum_{j\in\{1,2,\ldots,n\}}}_{=\sum_{j=1}^n} \underbrace{e_j^*(Te_j)}_{\substack{=m_{j,j}\\ \text{(by (13.111.8), applied}\\ \text{to } k=j)}} = \sum_{j=1}^n m_{j,j}\\ &= \sum_{i=1}^n m_{i,i} \qquad \text{(here, we renamed the summation index } j \text{ as } i)\,. \end{aligned}\tag{13.111.9}$$

But recall that if $\mathfrak{G}$ is any endomorphism of the $\mathbb{K}$-vector space V, then the trace of $\mathfrak{G}$ equals the trace of any matrix which represents $\mathfrak{G}$ with respect to a basis of V [801]. Applying this to $\mathfrak{G}=T$, we conclude that the trace of T equals the trace of any matrix which represents T with respect to a basis of V. In particular, the trace of T equals the trace of the matrix $(m_{i,j})_{1\leq i,j\leq n}$ (since $(m_{i,j})_{1\leq i,j\leq n}$ is a matrix which represents T with respect to the basis $(e_1,e_2,\ldots,e_n)$ of V). In other words, $\operatorname{trace} T=\operatorname{trace}\left((m_{i,j})_{1\leq i,j\leq n}\right)=\sum_{i=1}^n m_{i,i}$ (by the definition of $\operatorname{trace}\left((m_{i,j})_{1\leq i,j\leq n}\right)$). Compared with (13.111.9), this yields $\operatorname{trace} T=\sum_{i\in I} f_i(Ta_i)$. This proves Proposition 13.111.3. □

[*Remark:* Proposition 13.111.4 can be used to define the trace of an endomorphism of a finitely generated projective $\mathbb{K}$-module when $\mathbb{K}$ is a commutative ring. Indeed, if $\mathbb{K}$ is a commutative ring and if V is a finitely generated projective $\mathbb{K}$-module, and if $T:V\to V$ is a $\mathbb{K}$-linear map, then the trace $\operatorname{trace}(T)$ of T can be defined as $\sum_{i\in I} f_i(Ta_i)$, where $\left(I,(a_i)_{i\in I},(f_i)_{i\in I}\right)$ is a finite dual generating system for V. This notion of trace is well-defined[802] and generalizes the classical notion from linear algebra (which is defined only for finitely generated **free** $\mathbb{K}$-modules)[803]. But we will not concern ourselves with these generalizations, since our exercise deals only with representations of groups over a field.]

After all these preparations, we finally come to the actual solution of Exercise 4.1.14(b). Let U be any finite-dimensional $\mathbb{C}H$-module. We want to prove $\chi_{\operatorname{Ind}_\rho U}=\operatorname{Ind}_\rho \chi_U$.

For every $g\in G$, we define a $\mathbb{C}$-linear map $g^*:\mathbb{C}G\to\mathbb{C}$ by

$$\left(g^*(k)=\delta_{g,k} \qquad \text{for all } k\in G\right). \tag{13.111.10}$$

(This is well-defined, since $(k)_{k\in G}$ is a basis of the $\mathbb{C}$-vector space $\mathbb{C}G$.) Then,

$$\sum_{g\in G} g^*(\gamma)\cdot g=\gamma \qquad \text{for every } \gamma\in\mathbb{C}G. \tag{13.111.11}$$

have

$$e_k^*\left(\underbrace{v}_{=\sum\limits_{i=1}^n \lambda_i e_i}\right)=e_k^*\left(\sum_{i=1}^n \lambda_i e_i\right)=\lambda_k \qquad \text{(by (13.111.7))}\,.$$

Renaming k as i in this statement, we obtain the following: For each $i\in\{1,2,\ldots,n\}$, we have $e_i^*(v)=\lambda_i$. Thus, $\underbrace{\sum\limits_{i\in\{1,2,\ldots,n\}}}_{=\sum_{i=1}^n} \underbrace{e_i^*(v)}_{=\lambda_i} e_i=\sum\limits_{i=1}^n \lambda_i e_i$. Compared with $v=\sum\limits_{i=1}^n \lambda_i e_i$, this yields $v=\sum\limits_{i\in\{1,2,\ldots,n\}} e_i^*(v)\,e_i$, qed.

[801] Indeed, this is how the trace of $\mathfrak{G}$ is defined.

[802] because Proposition 13.111.4 shows that $\sum_{i\in I} f_i(Ta_i)$ does not depend on the choice of $\left(I,(a_i)_{i\in I},(f_i)_{i\in I}\right)$

[803] because Proposition 13.111.3 (or, more precisely, its straightforward generalization to free $\mathbb{K}$-modules over commutative rings) shows that these two notions give the same result when V is a free $\mathbb{K}$-module

[804] Also,

$$(gr)^{*}(\gamma r) = g^{*}(\gamma) \qquad \text{for all } g \in G,\ r \in G \text{ and } \gamma \in \mathbb{C}G \tag{13.111.12}$$

[805].

Proposition 13.111.2 (applied to $\mathbb{K} = \mathbb{C}$ and $V = U$) yields that a finite dual generating system for U exists if and only if the vector space U is finite-dimensional. Thus, a finite dual generating system for U exists (since the vector space U is finite-dimensional). Let us fix such a finite dual generating system for U, and denote it by $\left(J, (b_j)_{j\in J}, (g_j)_{j\in J}\right)$.

Hence, $\left(J, (b_j)_{j\in J}, (g_j)_{j\in J}\right)$ is a finite dual generating system for U. In other words, $\left(J, (b_j)_{j\in J}, (g_j)_{j\in J}\right)$ is a triple such that

- J is a finite set;
- $(b_j)_{j\in J}$ is a family of elements of U;
- $(g_j)_{j\in J}$ is a family of elements of U^{*} (where U^{*} means $\operatorname{Hom}_{\mathbb{C}}(U, \mathbb{C})$)

such that every $v \in U$ satisfies

$$v = \sum_{j\in J} g_j(v)\, b_j. \tag{13.111.13}$$

We now endow $\mathbb{C}G$ with the $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure that was used to define $\operatorname{Ind}_\rho U$. We recall that $\operatorname{Ind}_\rho U = \mathbb{C}G \otimes_{\mathbb{C}H} U$ (by the definition of $\operatorname{Ind}_\rho U$).

Let us fix $g \in G$. We define a map $\widetilde{F}_g : \mathbb{C}G \times U \to U$ by setting

$$\left(\widetilde{F}_g(\gamma, u) = \frac{1}{|H|} \sum_{h\in H} (g\rho(h))^{*}(\gamma)\, hu \qquad \text{for all } (\gamma, u) \in \mathbb{C}G \times U\right).$$

The map $\widetilde{F}_g$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U [806]. According to the universal property of the tensor product, this yields that there exists

[804] *Proof of (13.111.11):* Let $\gamma \in \mathbb{C}G$. We need to prove the equality (13.111.11). We notice that this equality is $\mathbb{C}$-linear in γ. Hence, we can WLOG assume that $\gamma \in G$ (since G is a basis of the $\mathbb{C}$-vector space $\mathbb{C}G$). Assume this. Now,

$$\begin{aligned}\sum_{g\in G} g^{*}(\gamma)\cdot g &= \sum_{g\in G} \underbrace{g^{*}(\gamma)}_{\substack{=\delta_{g,\gamma} \\ \text{(by (13.111.10), applied} \\ \text{to } k=\gamma \text{ (since } \gamma\in G))}} \cdot g = \sum_{g\in G} \delta_{g,\gamma}\cdot g \\ &= \sum_{\substack{g\in G;\\ g=\gamma}} \underbrace{\delta_{g,\gamma}}_{\substack{=1\\ \text{(since } g=\gamma)}} \cdot g + \sum_{\substack{g\in G;\\ g\neq\gamma}} \underbrace{\delta_{g,\gamma}}_{\substack{=0\\ \text{(since } g\neq\gamma)}} \cdot g = \sum_{\substack{g\in G;\\ g=\gamma}} 1\cdot g + \underbrace{\sum_{\substack{g\in G;\\ g\neq\gamma}} 0\cdot g}_{=0} \\ &= \sum_{\substack{g\in G;\\ g=\gamma}} \underbrace{1\cdot g}_{=g} = \sum_{\substack{g\in G;\\ g=\gamma}} g = \gamma \qquad (\text{since } \gamma \in G).\end{aligned}$$

This proves (13.111.11).

[805] *Proof of (13.111.12):* Let $g \in G$, $r \in G$ and $\gamma \in \mathbb{C}G$. We need to prove the equality (13.111.12). Since this equality is $\mathbb{C}$-linear in γ (because the maps $(gr)^{*}$ and g^{*} are $\mathbb{C}$-linear), we can WLOG assume that $\gamma \in G$ (since G is a basis of the $\mathbb{C}$-vector space $\mathbb{C}G$). Assume this.

We have $\gamma \in G$, and thus we can apply (13.111.10) to $k = \gamma$. We thus obtain $g^{*}(\gamma) = \delta_{g,\gamma}$. Also, $\underbrace{\gamma}_{\in G}\underbrace{r}_{\in G} \in GG \subset G$. Hence, (13.111.10) (applied to gr and γr instead of g and k) yields $(gr)^{*}(\gamma r) = \delta_{gr,\gamma r}$.

Now, we have $g = \gamma$ if and only if $gr = \gamma r$ (because G is a group). Now,

$$\begin{aligned} g^{*}(\gamma) = \delta_{g,\gamma} &= \begin{cases} 1, & \text{if } g = \gamma; \\ 0, & \text{if } g \neq \gamma \end{cases} = \begin{cases} 1, & \text{if } gr = \gamma r; \\ 0, & \text{if } gr \neq \gamma r \end{cases} \qquad (\text{since } g = \gamma \text{ if and only if } gr = \gamma r) \\ &= \delta_{gr,\gamma r} = (gr)^{*}(\gamma r).\end{aligned}$$

This proves (13.111.12).

[806] *Proof.* We notice that $\widetilde{F}_g(\gamma, u) = \frac{1}{|H|} \sum_{h\in H} (g\rho(h))^{*}(\gamma)\, hu$ depends $\mathbb{C}$-linearly on each of γ and u (for obvious reasons). In other words, the map $\widetilde{F}_g$ is $\mathbb{C}$-bilinear.

Now, let us fix $\gamma \in \mathbb{C}G$, $u \in U$ and $\kappa \in \mathbb{C}H$. We are going to prove the equality $\widetilde{F}_g(\gamma\kappa, u) = \widetilde{F}_g(\gamma, \kappa u)$.

a unique $\mathbb{C}$-linear map $F_g : \mathbb{C}G \otimes_{\mathbb{C}H} U \to U$ such that

$$\left(F_g\left(\gamma \otimes_{\mathbb{C}H} u\right) = \widetilde{F}_g\left(\gamma, u\right) \qquad \text{for all } \left(\gamma, u\right) \in \mathbb{C}G \times U\right).$$

Consider this map F_g.

So we know that any $(\gamma, u) \in \mathbb{C}G \times U$ satisfies

$$F_g\left(\gamma \otimes_{\mathbb{C}H} u\right) = \widetilde{F}_g\left(\gamma, u\right) = \frac{1}{|H|} \sum_{h \in H} \left(g\rho\left(h\right)\right)^* \left(\gamma\right) hu. \tag{13.111.14}$$

Let us now forget that we fixed g. We thus have constructed a $\mathbb{C}$-linear map $F_g : \mathbb{C}G \otimes_{\mathbb{C}H} U \to U$ for each $g \in G$. We have shown that this map satisfies (13.111.14) for any $(\gamma, u) \in \mathbb{C}G \times U$.

The set $G \times J$ is finite (since the sets G and J are finite). Now, we define a family $(a_i)_{i \in G \times J}$ of elements of $\mathbb{C}G \otimes_{\mathbb{C}H} U$ by

$$\left(a_{(k,j)} = k \otimes_{\mathbb{C}H} b_j \qquad \text{for all } (k, j) \in G \times J\right).$$

Furthermore, we define a family $(f_i)_{i \in G \times J}$ of elements of $(\mathbb{C}G \otimes_{\mathbb{C}H} U)^*$ by

$$\left(f_{(k,j)} = g_j \circ F_k \qquad \text{for all } (k, j) \in G \times J\right).$$

(This is well-defined because, for any $(k, j) \in G \times J$, the composition $g_j \circ F_k$ of the $\mathbb{C}$-linear maps $F_k : \mathbb{C}G \otimes_{\mathbb{C}H} U \to U$ and $g_j : U \to \mathbb{C}$ is a $\mathbb{C}$-linear map $\mathbb{C}G \otimes_{\mathbb{C}H} U \to \mathbb{C}$.)

Our goal is now to prove that $\left(G \times J, (a_i)_{i \in G \times J}, (f_i)_{i \in G \times J}\right)$ is a finite dual generating system for $\mathbb{C}G \otimes_{\mathbb{C}H} U$.

Since this equality is $\mathbb{C}$-linear in κ (because the map $\widetilde{F}_g$ is $\mathbb{C}$-bilinear), we can WLOG assume that $\kappa \in H$ (since H is a basis of the $\mathbb{C}$-vector space $\mathbb{C}H$). Assume this.

We have $\kappa \in H$. Thus, the map $H \to H,\ h \mapsto h\kappa$ is a bijection (since H is a group). Hence, we can substitute $h\kappa$ for h in the sum $\sum_{h \in H} (g\rho(h))^* (\gamma\rho(\kappa))\, hu$. As a result, we obtain $\sum_{h \in H} (g\rho(h))^* (\gamma\rho(\kappa))\, hu = \sum_{h \in H} (g\rho(h\kappa))^* (\gamma\rho(\kappa))\,(h\kappa)\, u$.

Now, the definition of $\widetilde{F}_g(\gamma\kappa, u)$ yields

$$\begin{aligned}\widetilde{F}_g\left(\gamma\kappa, u\right) &= \frac{1}{|H|} \underbrace{\sum_{h \in H} \left(g\rho\left(h\right)\right)^* \left(\gamma\rho\left(\kappa\right)\right) hu}_{= \sum_{h \in H} (g\rho(h\kappa))^* (\gamma\rho(\kappa))(h\kappa)u} = \frac{1}{|H|} \sum_{h \in H} \left(g \underbrace{\rho\left(h\kappa\right)}_{\substack{= \rho(h)\rho(\kappa) \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} \right)^* \left(\gamma\rho\left(\kappa\right)\right) \left(h\kappa\right) u \\ &= \frac{1}{|H|} \sum_{h \in H} \underbrace{\left(g\rho\left(h\right)\rho\left(\kappa\right)\right)^* \left(\gamma\rho\left(\kappa\right)\right)}_{\substack{= (g\rho(h))^*(\gamma) \\ \text{(by (13.111.12), applied to} \\ g\rho(h) \text{ and } \rho(\kappa) \text{ instead of } g \text{ and } r)}} h\kappa u = \frac{1}{|H|} \sum_{h \in H} \left(g\rho\left(h\right)\right)^* \left(\gamma\right) h\kappa u.\end{aligned}$$

Compared with

$$\widetilde{F}_g\left(\gamma, \kappa u\right) = \frac{1}{|H|} \sum_{h \in H} \left(g\rho\left(h\right)\right)^* \left(\gamma\right) h\kappa u \qquad \left(\text{by the definition of } \widetilde{F}_g\left(\gamma, \kappa u\right)\right),$$

this yields $\widetilde{F}_g(\gamma\kappa, u) = \widetilde{F}_g(\gamma, \kappa u)$.

Now let us forget that we fixed γ, u and κ. Thus, we have shown that $\widetilde{F}_g(\gamma\kappa, u) = \widetilde{F}_g(\gamma, \kappa u)$ for all $\gamma \in \mathbb{C}G$, $u \in U$ and $\kappa \in \mathbb{C}H$. This yields that the map $\widetilde{F}_g$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U (since we already know that this map $\widetilde{F}_g$ is $\mathbb{C}$-bilinear). Qed.

Indeed, every $v \in \mathbb{C}G \otimes_{\mathbb{C}H} U$ satisfies $v = \sum_{i \in G \times J} f_i(v) a_i$ [807]. Thus, we know that $\left(G \times J, (a_i)_{i \in G \times J}, (f_i)_{i \in G \times J} \right)$ is a triple such that

- $G \times J$ is a finite set;
- $(a_i)_{i \in G \times J}$ is a family of elements of $\mathbb{C}G \otimes_{\mathbb{C}H} U$;
- $(f_i)_{i \in G \times J}$ is a family of elements of $(\mathbb{C}G \otimes_{\mathbb{C}H} U)^*$ (where $(\mathbb{C}G \otimes_{\mathbb{C}H} U)^*$ means $\operatorname{Hom}_{\mathbb{C}} (\mathbb{C}G \otimes_{\mathbb{C}H} U, \mathbb{C})$)

[807] *Proof.* Let $v \in \mathbb{C}G \otimes_{\mathbb{C}H} U$. We need to prove the equality $v = \sum_{i \in G \times J} f_i(v) a_i$. Since this equality is $\mathbb{C}$-linear in v, we can WLOG assume that v is a pure tensor (since the pure tensors in $\mathbb{C}G \otimes_{\mathbb{C}H} U$ span the whole $\mathbb{C}$-vector space $\mathbb{C}G \otimes_{\mathbb{C}H} U$). Assume this. Thus, v is a pure tensor. In other words, $v = \gamma \otimes_{\mathbb{C}H} u$ for some $\gamma \in \mathbb{C}G$ and $u \in U$. Consider these γ and u.

We notice that for any $w \in G$, the map $G \to G,\ k \mapsto kw$ is a bijection (since G is a group). Hence, for any $w \in G$, we have

$$\begin{aligned}
\sum_{k \in G} (kw)^* (\gamma)\, kw &= \sum_{k \in G} k^* (\gamma)\, k && \left(\begin{array}{c} \text{here, we substituted } k \text{ for } kw \text{ in the sum,} \\ \text{since the map } G \to G,\ k \mapsto kw \text{ is a bijection} \end{array} \right) \\
&= \sum_{g \in G} g^* (\gamma)\, g && (\text{here, we renamed the summation index } k \text{ as } g) \\
&= \sum_{g \in G} g^* (\gamma) \cdot g = \gamma && (\text{by } (13.111.11)) . \qquad (13.111.15)
\end{aligned}$$

Now, every $h \in H$ satisfies

$$\begin{aligned}
\sum_{k \in G} (k\rho(h))^* (\gamma) \underbrace{kh}_{\substack{= k \cdot (\mathbb{C}[\rho])(h) \\ \text{(by the definition of the} \\ \text{right } \mathbb{C}H\text{-module} \\ \text{structure on } \mathbb{C}G)}} &= \sum_{k \in G} (k\rho(h))^* (\gamma)\, k \cdot \underbrace{(\mathbb{C}[\rho])(h)}_{\substack{= \rho(h) \\ (\text{since } h \in H)}} = \sum_{k \in G} (k\rho(h))^* (\gamma)\, k\rho(h) \\
&= \gamma \qquad (\text{by } (13.111.15), \text{ applied to } w = \rho(h)) . \qquad (13.111.16)
\end{aligned}$$

Now,

$$\begin{aligned}
\sum_{i \in G \times J} f_i(v) a_i &= \underbrace{\sum_{(k,j) \in G \times J}}_{= \sum_{k \in G} \sum_{j \in J}} \underbrace{f_{(k,j)}}_{= g_j \circ F_k} (v) \underbrace{a_{(k,j)}}_{= k \otimes_{\mathbb{C}H} b_j} \qquad (\text{here, we substituted } (k,j) \text{ for the summation index } i) \\
&= \sum_{k \in G} \underbrace{\sum_{j \in J} (g_j \circ F_k)(v)\, k \otimes_{\mathbb{C}H} b_j}_{\substack{= k \otimes_{\mathbb{C}H} \left(\sum_{j \in J} (g_j \circ F_k)(v) b_j \right) \\ \text{(since the tensor product is } \mathbb{C}\text{-bilinear)}}} = \sum_{k \in G} k \otimes_{\mathbb{C}H} \left(\sum_{j \in J} \underbrace{(g_j \circ F_k)(v)}_{= g_j(F_k(v))} b_j \right) \\
&= \sum_{k \in G} k \otimes_{\mathbb{C}H} \underbrace{\left(\sum_{j \in J} g_j (F_k(v))\, b_j \right)}_{\substack{= F_k(v) \\ \text{(because } F_k(v) = \sum_{j \in J} g_j(F_k(v)) b_j \\ \text{(by (13.111.13), applied to } F_k(v) \text{ instead of } v))}} = \sum_{k \in G} k \otimes_{\mathbb{C}H} F_k \left(\underbrace{v}_{= \gamma \otimes_{\mathbb{C}H} u} \right) \\
&= \sum_{k \in G} k \otimes_{\mathbb{C}H} \underbrace{F_k (\gamma \otimes_{\mathbb{C}H} u)}_{\substack{= \frac{1}{|H|} \sum_{h \in H} (k\rho(h))^* (\gamma) hu \\ \text{(by (13.111.14), applied to } g = k)}} = \sum_{k \in G} k \otimes_{\mathbb{C}H} \left(\frac{1}{|H|} \sum_{h \in H} (k\rho(h))^* (\gamma)\, hu \right) \\
&= \frac{1}{|H|} \underbrace{\sum_{k \in G} \sum_{h \in H}}_{= \sum_{h \in H} \sum_{k \in G}} (k\rho(h))^* (\gamma)\, k \otimes_{\mathbb{C}H} hu \qquad (\text{since the tensor product is } \mathbb{C}\text{-bilinear}) \\
&= \frac{1}{|H|} \sum_{h \in H} \sum_{k \in G} (k\rho(h))^* (\gamma) \underbrace{k \otimes_{\mathbb{C}H} hu}_{\substack{= kh \otimes_{\mathbb{C}H} u \\ \text{(since } h \text{ can be moved past} \\ \text{the } \otimes_{\mathbb{C}H} \text{ sign (since } h \in H \subset \mathbb{C}H))}} = \frac{1}{|H|} \sum_{h \in H} \sum_{k \in G} (k\rho(h))^* (\gamma)\, kh \otimes_{\mathbb{C}H} u \\
&= \frac{1}{|H|} \sum_{h \in H} \underbrace{\left(\sum_{k \in G} (k\rho(h))^* (\gamma)\, kh \right)}_{\substack{= \gamma \\ \text{(by (13.111.16))}}} \otimes_{\mathbb{C}H} u = \frac{1}{|H|} \sum_{h \in H} \underbrace{\gamma \otimes_{\mathbb{C}H} u}_{= v} = \frac{1}{|H|} \underbrace{\sum_{h \in H} v}_{= |H| \cdot v} = \frac{1}{|H|} |H| \cdot v = v.
\end{aligned}$$

such that every $v \in \mathbb{C}G \otimes_{\mathbb{C}H} U$ satisfies $v = \sum_{i \in G \times J} f_i(v)\, a_i$. In other words, $\left(G \times J, (a_i)_{i \in G \times J}, (f_i)_{i \in G \times J}\right)$ is a finite dual generating system for $\mathbb{C}G \otimes_{\mathbb{C}H} U$ (because this is precisely how a "finite dual generating system" was defined). In other words, $\left(G \times J, (a_i)_{i \in G \times J}, (f_i)_{i \in G \times J}\right)$ is a finite dual generating system for $\operatorname{Ind}_\rho U$ (since $\operatorname{Ind}_\rho U = \mathbb{C}G \otimes_{\mathbb{C}H} U$).

Let us now notice that

$$\sum_{j \in J} g_j(hb_j) = \chi_U(h) \qquad \text{for every } h \in H \tag{13.111.17}$$

[808].

Now, let us fix $g \in G$. We want to compute $\chi_{\operatorname{Ind}_\rho U}(g)$. The definition of $\chi_{\operatorname{Ind}_\rho U}(g)$ yields $\chi_{\operatorname{Ind}_\rho U}(g) = \operatorname{trace}(g : \operatorname{Ind}_\rho U \to \operatorname{Ind}_\rho U)$. But Proposition 13.111.3 (applied to $\mathbb{K} = \mathbb{C}$, $V = \operatorname{Ind}_\rho U$, $I = G \times J$ and $T = (g : \operatorname{Ind}_\rho U \to \operatorname{Ind}_\rho U)$) yields

$$\begin{aligned}
&\operatorname{trace}(g : \operatorname{Ind}_\rho U \to \operatorname{Ind}_\rho U) \\
&= \sum_{i \in G \times J} f_i \left(\underbrace{(g : \operatorname{Ind}_\rho U \to \operatorname{Ind}_\rho U)\, a_i}_{= g a_i} \right) = \sum_{i \in G \times J} f_i(g a_i) \\
&= \sum_{(k,j) \in G \times J} \underbrace{f_{(k,j)}}_{= g_j \circ F_k} \left(g \underbrace{a_{(k,j)}}_{= k \otimes_{\mathbb{C}H} b_j} \right) \qquad \text{(here, we substituted } (k,j) \text{ for the summation index } i\text{)} \\
&= \sum_{(k,j) \in G \times J} (g_j \circ F_k) \underbrace{(g(k \otimes_{\mathbb{C}H} b_j))}_{= gk \otimes_{\mathbb{C}H} b_j} = \sum_{(k,j) \in G \times J} \underbrace{(g_j \circ F_k)(gk \otimes_{\mathbb{C}H} b_j)}_{= g_j(F_k(gk \otimes_{\mathbb{C}H} b_j))} \\
&= \sum_{(k,j) \in G \times J} g_j \left(\underbrace{F_k(gk \otimes_{\mathbb{C}H} b_j)}_{\substack{= \frac{1}{|H|} \sum_{h \in H} (k\rho(h))^* (gk) h b_j \\ \text{(by (13.111.14), applied to } k,\ gk \text{ and } b_j \\ \text{instead of } g,\ \gamma \text{ and } u)}} \right) \\
&= \underbrace{\sum_{(k,j) \in G \times J}}_{= \sum_{k \in G} \sum_{j \in J}} \underbrace{g_j \left(\frac{1}{|H|} \sum_{h \in H} (k\rho(h))^* (gk)\, h b_j \right)}_{\substack{= \frac{1}{|H|} \sum_{h \in H} (k\rho(h))^* (gk) g_j(hb_j) \\ \text{(since the map } g_j \text{ is } \mathbb{C}\text{-linear)}}} = \sum_{k \in G} \sum_{j \in J} \frac{1}{|H|} \sum_{h \in H} (k\rho(h))^* (gk)\, g_j(hb_j) \\
&= \sum_{k \in G} \frac{1}{|H|} \sum_{h \in H} (k\rho(h))^* (gk) \sum_{j \in J} g_j(hb_j).
\end{aligned} \tag{13.111.18}$$

Thus, $v = \sum_{i \in G \times J} f_i(v)\, a_i$ is proven, qed.

[808] *Proof of (13.111.17):* Let $h \in H$. The definition of $\chi_U(h)$ yields $\chi_U(h) = \operatorname{trace}(h : U \to U)$. But Proposition 13.111.3 (applied to $\mathbb{C}$, U, $\left(J, (b_j)_{j \in J}, (g_j)_{j \in J}\right)$ and $(h : U \to U)$ instead of $\mathbb{C}$, U, $\left(I, (a_i)_{i \in I}, (f_i)_{i \in I}\right)$ and T) yields

$$\operatorname{trace}(h : U \to U) = \sum_{j \in J} g_j \left(\underbrace{(h : U \to U)\, b_j}_{= h b_j} \right) = \sum_{j \in J} g_j(hb_j).$$

Thus, $\chi_U(h) = \operatorname{trace}(h : U \to U) = \sum_{j \in J} g_j(hb_j)$. This proves (13.111.17).

But every $k \in G$ satisfies

$$\begin{aligned}
&\sum_{h\in H} \underbrace{(k\rho(h))^*(gk)}_{\substack{=\delta_{k\rho(h),gk} \\ \text{(by (13.111.10), applied to } k\rho(h) \\ \text{and } gk \text{ instead of } g \text{ and } k\text{)}}} \underbrace{\sum_{j\in J} g_j(hb_j)}_{\substack{=\chi_U(h) \\ \text{(by (13.111.17))}}} \\
&= \sum_{h\in H} \delta_{k\rho(h),gk}\chi_U(h) \\
&= \underbrace{\sum_{\substack{h\in H;\\ k\rho(h)=gk}}}_{\substack{=\sum_{\substack{h\in H;\\ k\rho(h)k^{-1}=g}} \\ \text{(because for every } h\in H\text{,} \\ \text{the statement } (k\rho(h)=gk) \\ \text{is equivalent} \\ \text{to } (k\rho(h)k^{-1}=g)\text{)}}} \underbrace{\delta_{k\rho(h),gk}}_{\substack{=1 \\ \text{(since } k\rho(h)=gk\text{)}}} \chi_U(h) + \sum_{\substack{h\in H;\\ k\rho(h)\neq gk}} \underbrace{\delta_{k\rho(h),gk}}_{\substack{=0 \\ \text{(since } k\rho(h)\neq gk\text{)}}} \chi_U(h) \\
&= \sum_{\substack{h\in H;\\ k\rho(h)k^{-1}=g}} 1\chi_U(h) + \underbrace{\sum_{\substack{h\in H;\\ k\rho(h)\neq gk}} 0\chi_U(h)}_{=0} = \sum_{\substack{h\in H;\\ k\rho(h)k^{-1}=g}} 1\chi_U(h) \\
&= \sum_{\substack{h\in H;\\ k\rho(h)k^{-1}=g}} \chi_U(h).
\end{aligned} \tag{13.111.19}$$

Now, recall that

$$\begin{aligned}
\chi_{\operatorname{Ind}_\rho U}(g) &= \operatorname{trace}(g : \operatorname{Ind}_\rho U \to \operatorname{Ind}_\rho U) \\
&= \sum_{k\in G} \frac{1}{|H|} \underbrace{\sum_{h\in H} (k\rho(h))^*(gk) \sum_{j\in J} g_j(hb_j)}_{\substack{=\sum_{\substack{h\in H;\\ k\rho(h)k^{-1}=g}} \chi_U(h) \\ \text{(by (13.111.19))}}} \qquad \text{(by (13.111.18))} \\
&= \sum_{k\in G} \frac{1}{|H|} \sum_{\substack{h\in H;\\ k\rho(h)k^{-1}=g}} \chi_U(h) = \frac{1}{|H|} \underbrace{\sum_{\substack{h\in H;\\ k\rho(h)k^{-1}=g}} \sum_{k\in G}}_{=\sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}}} \chi_U(h) = \frac{1}{|H|} \sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}} \chi_U(h).
\end{aligned}$$

Compared with

$$(\operatorname{Ind}_\rho \chi_U)(g) = \frac{1}{|H|} \sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}} \chi_U(h) \qquad \text{(by the definition of } (\operatorname{Ind}_\rho \chi_U)(g)\text{)},$$

this yields $\chi_{\operatorname{Ind}_\rho U}(g) = (\operatorname{Ind}_\rho \chi_U)(g)$.

Now, let us forget that we fixed g. We thus have proven that $\chi_{\operatorname{Ind}_\rho U}(g) = (\operatorname{Ind}_\rho \chi_U)(g)$ for every $g \in G$. In other words, $\chi_{\operatorname{Ind}_\rho U} = \operatorname{Ind}_\rho \chi_U$. This solves Exercise 4.1.14(b).

(c) Assume that H is a subgroup of G, and that $\rho : H \to G$ is the inclusion map. We need to show that $\operatorname{Ind}_\rho f = \operatorname{Ind}_H^G f$ for every $f \in R_{\mathbb{C}}(H)$.

We notice that the map $G \to G,\ k \mapsto k^{-1}$ is a bijection (since G is a group).

Let $f \in R_{\mathbb{C}}(H)$. Let $g \in G$. Then, the definition of $(\operatorname{Ind}_\rho f)(g)$ yields

$$\begin{aligned}
(\operatorname{Ind}_\rho f)(g) &= \frac{1}{|H|} \underbrace{\sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}}}_{\substack{=\sum_{\substack{(h,k)\in H\times G;\\ khk^{-1}=g}}\\ \text{(since } \rho(h)=h \text{ for every } h\in H\\ \text{(since } \rho:H\to G \text{ is the inclusion map))}}} f(h) = \frac{1}{|H|} \underbrace{\sum_{\substack{(h,k)\in H\times G;\\ khk^{-1}=g}}}_{=\sum_{k\in G}\sum_{\substack{h\in H;\\ khk^{-1}=g}}} f(h) \\
&= \frac{1}{|H|} \sum_{k\in G} \underbrace{\sum_{\substack{h\in H;\\ khk^{-1}=g}}}_{\substack{=\sum_{\substack{h\in H;\\ h=k^{-1}gk}}\\ \text{(because for every } h\in H,\\ \text{the statement } \left(khk^{-1}=g\right) \text{ is}\\ \text{equivalent to } \left(h=k^{-1}gk\right))}} f(h) \\
&= \frac{1}{|H|} \underbrace{\sum_{k\in G} \sum_{\substack{h\in H;\\ h=k^{-1}gk}} f(h)}_{\substack{=\sum_{\substack{k\in G;\\ k^{-1}gk\in H}} \sum_{\substack{h\in H;\\ h=k^{-1}gk}} f(h) + \sum_{\substack{k\in G;\\ k^{-1}gk\notin H}} \sum_{\substack{h\in H;\\ h=k^{-1}gk}} f(h)\\ \text{(since every } k\in G \text{ satisfies either } k^{-1}gk\in H \text{ or } k^{-1}gk\notin H \text{ (but never both))}}} \\
&= \frac{1}{|H|} \left(\sum_{\substack{k\in G;\\ k^{-1}gk\in H}} \underbrace{\sum_{\substack{h\in H;\\ h=k^{-1}gk}} f(h)}_{\substack{=f\left(k^{-1}gk\right)\\ \text{(since } k^{-1}gk\in H)}} + \sum_{\substack{k\in G;\\ k^{-1}gk\notin H}} \underbrace{\sum_{\substack{h\in H;\\ h=k^{-1}gk}} f(h)}_{\substack{=\text{(empty sum)}\\ \text{(since there is no } h\in H \text{ satisfying } h=k^{-1}gk\\ \text{(because } k^{-1}gk\notin H))}} \right) \\
&= \frac{1}{|H|} \left(\sum_{\substack{k\in G;\\ k^{-1}gk\in H}} f\left(k^{-1}gk\right) + \sum_{\substack{k\in G;\\ k^{-1}gk\notin H}} \underbrace{\text{(empty sum)}}_{=0} \right) = \frac{1}{|H|} \left(\sum_{\substack{k\in G;\\ k^{-1}gk\in H}} f\left(k^{-1}gk\right) + \underbrace{\sum_{\substack{k\in G;\\ k^{-1}gk\notin H}} 0}_{=0} \right) \\
&= \frac{1}{|H|} \sum_{\substack{k\in G;\\ k^{-1}gk\in H}} f\left(k^{-1}gk\right) = \frac{1}{|H|} \underbrace{\sum_{\substack{k\in G;\\ \left(k^{-1}\right)^{-1}gk^{-1}\in H}}}_{\substack{=\sum_{\substack{k\in G;\\ kgk^{-1}\in H}}\\ \text{(since } \left(k^{-1}\right)^{-1}=k \text{ for every } k\in G)}} f\Bigg(\underbrace{\left(k^{-1}\right)^{-1}}_{=k} gk^{-1} \Bigg) \\
&\qquad \left(\begin{array}{c} \text{here, we substituted } k^{-1} \text{ for } k \text{ in the sum, since} \\ \text{the map } G\to G,\ k\mapsto k^{-1} \text{ is a bijection} \end{array} \right) \\
&= \frac{1}{|H|} \sum_{\substack{k\in G;\\ kgk^{-1}\in H}} f\left(kgk^{-1}\right) = \left(\operatorname{Ind}_H^G f\right)(g)
\end{aligned}$$

(since (4.1.4) yields $\left(\operatorname{Ind}_H^G f\right)(g) = \dfrac{1}{|H|} \sum\limits_{\substack{k \in G; \\ kgk^{-1} \in H}} f\left(kgk^{-1}\right)$).

Let us now forget that we fixed g. We thus have proven that $\left(\operatorname{Ind}_\rho f\right)(g) = \left(\operatorname{Ind}_H^G f\right)(g)$ for every $g \in G$. In other words, $\operatorname{Ind}_\rho f = \operatorname{Ind}_H^G f$. This solves Exercise 4.1.14(c).

(d) Assume that H is a subgroup of G, and that $\rho : H \to G$ is the inclusion map. We need to show that $\operatorname{Ind}_\rho U = \operatorname{Ind}_H^G U$ for every $\mathbb{C}H$-module U.

We notice that $\rho : H \to G$ is the inclusion map. Hence, $\mathbb{C}[\rho] : \mathbb{C}H \to \mathbb{C}G$ is also the inclusion map (since we identify $\mathbb{C}H$ with a $\mathbb{C}$-subalgebra of $\mathbb{C}G$ along this map $\mathbb{C}[\rho]$). Thus,

$$(\mathbb{C}[\rho])\,\eta = \eta \qquad \text{for every } \eta \in \mathbb{C}H. \tag{13.111.20}$$

Let U be a $\mathbb{C}H$-module. Both $\operatorname{Ind}_H^G U$ and $\operatorname{Ind}_\rho U$ are defined as $\mathbb{C}G \otimes_{\mathbb{C}H} U$ for some $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure on $\mathbb{C}G$; however, their definitions differ at how this $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure is defined. We are now going to prove that these two $(\mathbb{C}G, \mathbb{C}H)$-bimodule structures on $\mathbb{C}G$ are identical.

The definition of $\operatorname{Ind}_\rho U$ shows that we have

$$\operatorname{Ind}_\rho U = \mathbb{C}G \otimes_{\mathbb{C}H} U, \tag{13.111.21}$$

where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}H)$-bimodule according to the following rule: The left $\mathbb{C}G$-module structure on $\mathbb{C}G$ is plain multiplication inside $\mathbb{C}G$; the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho] : \mathbb{C}H \to \mathbb{C}G$ (thus, it is explicitly given by $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho])\,\eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$). We denote this $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure on $\mathbb{C}G$ as the *first structure*.

On the other hand, the definition of $\operatorname{Ind}_H^G U$ shows that we have

$$\operatorname{Ind}_H^G U = \mathbb{C}G \otimes_{\mathbb{C}H} U, \tag{13.111.22}$$

where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}H)$-bimodule in the usual way (i.e., the left $\mathbb{C}G$-module structure on $\mathbb{C}G$ is plain multiplication inside $\mathbb{C}G$, and the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is also plain multiplication inside $\mathbb{C}G$ because $\mathbb{C}H \subset \mathbb{C}G$). We denote this $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure on $\mathbb{C}G$ as the *second structure*.

The right hand sides of the equalities (13.111.21) and (13.111.22) appear identical, but so far we do not know if they actually mean the same thing, because the meanings of "$\mathbb{C}G$" possibly differ. Namely, we have two $(\mathbb{C}G, \mathbb{C}H)$-bimodule structures on the $\mathbb{C}$-vector space $\mathbb{C}G$: the first structure (used in (13.111.21)) and the second structure (used in (13.111.22)). These two structures clearly have the same left $\mathbb{C}G$-module structure. But they also have the same right $\mathbb{C}H$-module structure, because every $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$ satisfy

$$\begin{aligned}
&(\text{the result of the right action of } \eta \text{ on } \gamma \text{ according to the first structure}) \\
&= \gamma \cdot \underbrace{(\mathbb{C}[\rho])\,\eta}_{\substack{=\eta \\ (\text{by } (13.111.20))}} = \gamma \cdot \eta \\
&= (\text{the result of the right action of } \eta \text{ on } \gamma \text{ according to the second structure}).
\end{aligned}$$

Hence, the first structure and the second structure are identical. Thus, the right hand sides of the equalities (13.111.21) and (13.111.22) really mean the same thing. Thus, comparing the equalities (13.111.21) and (13.111.22), we obtain $\operatorname{Ind}_\rho U = \operatorname{Ind}_H^G U$ as left $\mathbb{C}G$-modules. This solves Exercise 4.1.14(d).

(e) Assume that $G = H/K$ for some normal subgroup K of H. Let $\rho : H \to G$ be the projection map. We want to prove that $\operatorname{Ind}_\rho f = f^K$ for every $f \in R_{\mathbb{C}}(H)$.

Let $f \in R_{\mathbb{C}}(H)$. Applying (13.111.1) to H instead of K, we obtain the following equivalence:

$$\begin{aligned}
&(f \in R_{\mathbb{C}}(H)) \\
\iff &(\text{any two conjugate elements } k \text{ and } k' \text{ of } H \text{ satisfy } f(k) = f(k')).
\end{aligned}$$

Hence,

$$(\text{any two conjugate elements } k \text{ and } k' \text{ of } H \text{ satisfy } f(k) = f(k')) \tag{13.111.23}$$

(since we know that $f \in R_{\mathbb{C}}(H)$). Thus,

$$f\left(y^{-1}zy\right) = f(z) \qquad \text{for all } z \in H \text{ and } y \in H \tag{13.111.24}$$

(because if $z \in H$ and $y \in H$, then $y^{-1}zy$ and z are two conjugate elements of H).

Let $g \in G$. Then, $g \in G = H/K$. Hence, there exists an $x \in H$ such that $g = xK$. Consider this x. The map $\rho : H \to G$ is the projection map from H to $G = H/K$, and thus sends every $h \in H$ to the coset $hK \in G$. In other words, $\rho(h) = hK$ for every $h \in H$. Applied to $h = x$, this yields $\rho(x) = xK = g$. Of course, $\ker \rho = K$ (since ρ is the projection map from H to H/K).

We have $|G| = |H/K| = [H : K] = |H| / |K|$.

We make another simple observation: If $h \in H$ and $y \in H$, then we have the following logical equivalence:

$$\left(\rho(h) = (\rho(y))^{-1} g \rho(y)\right) \iff \left(h \in y^{-1} x K y\right). \tag{13.111.25}$$

[809]

The definition of f^K yields $f^K(xK) = \dfrac{1}{|K|} \sum_{k \in K} f(xk)$. Hence,

$$f^K\left(\underbrace{g}_{=xK}\right) = f^K(xK) = \frac{1}{|K|} \sum_{k \in K} f(xk). \tag{13.111.26}$$

But the definition of $(\operatorname{Ind}_\rho f)(g)$ yields

$$\begin{aligned}
(\operatorname{Ind}_\rho f)(g) &= \frac{1}{|H|} \underbrace{\sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = g}}}_{\substack{= \sum_{\substack{(h,k) \in H \times G; \\ \rho(h) = k^{-1}gk}} \\ \text{(because for any } (h,k) \in H \times G, \\ \text{the statement } \left(k\rho(h)k^{-1} = g\right) \\ \text{is equivalent to } \left(\rho(h) = k^{-1}gk\right))}} f(h) = \frac{1}{|H|} \underbrace{\sum_{\substack{(h,k) \in H \times G; \\ \rho(h) = k^{-1}gk}}}_{= \sum_{k \in G} \sum_{\substack{h \in H; \\ \rho(h) = k^{-1}gk}}} f(h) \\
&= \frac{1}{|H|} \sum_{k \in G} \sum_{\substack{h \in H; \\ \rho(h) = k^{-1}gk}} f(h) = \frac{1}{|H|} \sum_{p \in G} \sum_{\substack{h \in H; \\ \rho(h) = p^{-1}gp}} f(h) \qquad (13.111.27)
\end{aligned}$$

[809] *Proof of (13.111.25):* Let $h \in H$ and $y \in H$. Recall that the map $\rho : H \to G$ is the projection map from H to $G = H/K$. Thus, $\rho(w) = wK$ for every $w \in H$.

We have the following chain of equivalences:

$$\begin{aligned}
&\left(\rho(h) = (\rho(y))^{-1} g \rho(y)\right) \\
&\iff (\rho(y)\rho(h) = g\rho(y)) \iff \left(\underbrace{\rho(y)\rho(h)(\rho(y))^{-1}}_{\substack{= \rho\left(yhy^{-1}\right) \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} = \underbrace{g}_{= \rho(x)}\right) \\
&\iff \left(\underbrace{\rho\left(yhy^{-1}\right)}_{\substack{= yhy^{-1}K \\ \text{(since } \rho(w) = wK \text{ for every } w \in H)}} = \underbrace{\rho(x)}_{\substack{= xK \\ \text{(since } \rho(w) = wK \text{ for every } w \in H)}}\right) \iff \left(yhy^{-1}K = xK\right) \\
&\iff \left(yhy^{-1} \in xK\right) \iff (yh \in xKy) \iff \left(h \in y^{-1}xKy\right).
\end{aligned}$$

This proves (13.111.25).

(here, we renamed the index k as p in the first sum). But every $p \in G$ satisfies $\sum\limits_{\substack{h\in H;\\ \rho(h)=p^{-1}gp}} f(h) = \sum\limits_{k\in K} f(xk)$ [810]. Hence, (13.111.27) becomes

$$\left(\operatorname{Ind}_\rho f\right)(g) = \frac{1}{|H|} \sum_{p\in G} \underbrace{\sum_{\substack{h\in H;\\ \rho(h)=p^{-1}gp}} f(h)}_{=\sum_{k\in K} f(xk)} = \frac{1}{|H|} \underbrace{\sum_{p\in G}\sum_{k\in K} f(xk)}_{=|G|\cdot\sum_{k\in K} f(xk)} = \frac{1}{|H|} \underbrace{|G|}_{=|H|/|K|} \cdot \sum_{k\in K} f(xk)$$

$$= \underbrace{\frac{1}{|H|}\cdot |H|/|K|}_{=\frac{1}{|K|}} \cdot \sum_{k\in K} f(xk) = \frac{1}{|K|} \sum_{k\in K} f(xk) = f^K(g)$$

(by (13.111.26)).

Let us now forget that we fixed g. We thus have shown that $\left(\operatorname{Ind}_\rho f\right)(g) = f^K(g)$ for every $g \in G$. In other words, $\operatorname{Ind}_\rho f = f^K$. This solves Exercise 4.1.14(e).

(f) Assume that $G = H/K$ for some normal subgroup K of H. Let $\rho : H \to G$ be the projection map. We want to prove that $\operatorname{Ind}_\rho U \cong U^K$ for every $\mathbb{C}H$-module U.

The map ρ is the projection map from H to $G = H/K$. Thus, the map ρ is surjective and has kernel $\ker\rho = K$. Furthermore,

$$\left|\rho^{-1}(g)\right| = |K| \qquad \text{for every } g \in G. \tag{13.111.29}$$

[811]

Let U be a $\mathbb{C}H$-module. Recall that U^K is a $\mathbb{C}[H/K]$-module, thus a $\mathbb{C}G$-module (since $H/K = G$).

Recall that $\operatorname{Ind}_\rho U$ is defined as the $\mathbb{C}G$-module $\mathbb{C}G \otimes_{\mathbb{C}H} U$, where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}H)$-bimodule according to the following rule: The left $\mathbb{C}G$-module structure on $\mathbb{C}G$ is plain multiplication inside $\mathbb{C}G$; the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho] : \mathbb{C}H \to \mathbb{C}G$ (thus, it is explicitly given by $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho])\eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$). From now on, we regard $\mathbb{C}G$ as endowed with this $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure.

[810] *Proof.* Let $p \in G$. Then, $p \in G = H/K$. Hence, there exists a $y \in H$ such that $p = yK$. Consider this y.

Recall that $\rho(h) = hK$ for every $h \in H$. Applying this to $h = y$, we obtain $\rho(y) = yK = p$.

We notice that the map $K \to y^{-1}xKy,\ k \mapsto y^{-1}xky$ is a bijection (since H is a group).

Now, for every $h \in H$, we have the following equivalence:

$$\begin{aligned} \left(\rho(h) = p^{-1}gp\right) &\iff \left(\rho(h) = (\rho(y))^{-1} g\rho(y)\right) && (\text{since } p = \rho(y)) \\ &\iff \left(h \in y^{-1}xKy\right) && (\text{according to } (13.111.25)). \end{aligned} \tag{13.111.28}$$

Now,

$$\underbrace{\sum_{\substack{h\in H;\\ \rho(h)=p^{-1}gp}}}_{\substack{=\sum_{\substack{h\in H;\\ h\in y^{-1}xKy}} \\ (\text{because for every } h\in H, \text{ the statement} \\ \left(\rho(h)=p^{-1}gp\right) \text{ is equivalent to } \left(h\in y^{-1}xKy\right) \\ (\text{because of } (13.111.28)))}} f(h) = \underbrace{\sum_{\substack{h\in H;\\ h\in y^{-1}xKy}}}_{\substack{=\sum_{h\in y^{-1}xKy} \\ (\text{since } y^{-1}xKy\subset H)}} f(h) = \sum_{h\in y^{-1}xKy} f(h) = \sum_{k\in K} f\left(y^{-1}xky\right)$$

(here, we substituted $y^{-1}xky$ for h in the sum, since the map $K \to y^{-1}xKy,\ k \mapsto y^{-1}xky$ is a bijection). Thus,

$$\sum_{\substack{h\in H;\\ \rho(h)=p^{-1}gp}} f(h) = \sum_{k\in K} \underbrace{f\left(y^{-1}xky\right)}_{\substack{=f(xk) \\ (\text{by } (13.111.24), \text{ applied to } z=xk)}} = \sum_{k\in K} f(xk),$$

qed.

[811] *Proof of (13.111.29):* Let $g \in G$. The map ρ is surjective. Hence, $\rho(H) = G$. Thus, $g \in G = \rho(H)$. Therefore, there exists some $x \in H$ such that $g = \rho(x)$. Let us fix such an x.

We know that H is a group. Hence, the map $K \to xK,\ k \mapsto xk$ is a bijection. Thus, the sets K and xK are in bijection. Therefore, $|xK| = |K|$.

We define a map $\alpha : U^K \to \mathbb{C}G \otimes_{\mathbb{C}H} U$ by setting

$$\alpha(u) = 1 \otimes_{\mathbb{C}H} u \qquad \text{for every } u \in U^K.$$

This α is a map $U^K \to \operatorname{Ind}_\rho U$ (since $\operatorname{Ind}_\rho U = \mathbb{C}G \otimes_{\mathbb{C}H} U$) and is $\mathbb{C}$-linear (since $\alpha(u) = 1 \otimes_{\mathbb{C}H} u$ depends $\mathbb{C}$-linearly on u).

We will show that α is a $\mathbb{C}G$-module isomorphism.

The $\mathbb{C}G$-module structure on U^K has the property that

$$\rho(h) \cdot v = hv \qquad \text{for any } h \in H \text{ and } v \in U^K. \tag{13.111.30}$$

[812]

Now, α is a $\mathbb{C}G$-module homomorphism[813]. We will eventually construct an inverse to α; but first we need to prepare.

For every $g \in G$ and every $p \in \mathbb{C}G$, we denote by $\epsilon_g(p)$ the g-coordinate of p with respect to the basis G of the $\mathbb{C}$-vector space $\mathbb{C}G$. By the definition of "coordinate", we have

$$q = \sum_{g \in G} \epsilon_g(q)\, g \qquad \text{for every } q \in \mathbb{C}G. \tag{13.111.32}$$

However, for every $y \in H$, we have the following logical equivalence:

$$\left(y \in \rho^{-1}(g)\right) \iff \left(\rho(y) = \underbrace{g}_{=\rho(x)}\right) \iff (\rho(y) = \rho(x)) \iff \left(\underbrace{\rho(y) \cdot (\rho(x))^{-1}}_{\substack{=\rho(yx^{-1}) \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} = 1\right)$$

$$\iff \left(\rho\left(yx^{-1}\right) = 1\right) \iff \left(yx^{-1} \in \underbrace{\ker \rho}_{=K}\right) \iff \left(yx^{-1} \in K\right) \iff (y \in xK).$$

Hence, $\rho^{-1}(g) = xK$, so that $\left|\rho^{-1}(g)\right| = |xK| = |K|$. This proves (13.111.29).

[812] *Proof of (13.111.30):* The map ρ is the projection map from H to H/K. Thus, the map ρ sends every $h \in H$ to the coset $hK \in H/K$. In other words,

$$\rho(h) = hK \qquad \text{for every } h \in H, \tag{13.111.31}$$

where hK means the coset $hK \in H/K$. But by the definition of the $\mathbb{C}[H/K]$-module structure on U^K, we have

$$(hK) \cdot v = hv \qquad \text{for any } h \in H \text{ and } v \in U^K,$$

where hK means the coset $hK \in H/K$. Thus, any $h \in H$ and $v \in U^K$ satisfy

$$\underbrace{\rho(h)}_{\substack{=hK \\ \text{(by (13.111.31))}}} \cdot v = (hK) \cdot v = hv,$$

where hK means the coset $hK \in H/K$. This proves (13.111.30).

[813] *Proof.* Let $u \in U^K$ and $g \in G$. We have $g \in G = \rho(H)$ (since the map $\rho : H \to G$ is surjective). Thus, $g = \rho(y)$ for some $y \in H$. Let us consider this y.

Applying (13.111.30) to $h = y$ and $v = u$, we obtain $\rho(y) \cdot u = yu$. Thus, $\underbrace{g}_{=\rho(y)} u = \rho(y) \cdot u = yu$.

Now, the definition of $\alpha(gu)$ yields

$$\alpha(gu) = 1 \otimes_{\mathbb{C}H} \underbrace{gu}_{=yu} = 1 \otimes_{\mathbb{C}H} yu = 1y \otimes_{\mathbb{C}H} u$$

(here, we moved the y past the tensor sign; this is allowed because $y \in H \subset \mathbb{C}H$).

By the definition of the left $\mathbb{C}G$-module structure on $\mathbb{C}G$, we have $g \cdot 1 = g1 = g$.

By the definition of the right $\mathbb{C}H$-module structure on $\mathbb{C}G$, we have $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho])\eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$. Applying this to $\gamma = 1$ and $\eta = y$, we obtain $1y = 1 \cdot (\mathbb{C}[\rho])y$. But $y \in H$ and thus $(\mathbb{C}[\rho])y = \rho(y) = g$. Therefore, $1y = 1 \cdot \underbrace{(\mathbb{C}[\rho])y}_{=g} = 1 \cdot g = g = g \cdot 1$.

Now, $\alpha(gu) = \underbrace{1y}_{=g\cdot 1} \otimes_{\mathbb{C}H} u = g \cdot 1 \otimes_{\mathbb{C}H} u$. Compared with $g \cdot \underbrace{\alpha(u)}_{=1\otimes_{\mathbb{C}H} u} = g \cdot (1 \otimes_{\mathbb{C}H} u) = g \cdot 1 \otimes_{\mathbb{C}H} u$, this yields $\alpha(gu) = g \cdot \alpha(u)$.

Now, let us forget that we fixed u and g. We thus have shown that $\alpha(gu) = g \cdot \alpha(u)$ for all $u \in U^K$ and $g \in G$. Thus, the map α is a homomorphism of G-sets. Since the map α is also $\mathbb{C}$-linear, this yields that α is a $\mathbb{C}G$-module homomorphism. Qed.

For every $g \in G$, we have defined a map $\epsilon_g : \mathbb{C}G \to \mathbb{C}$ (because we have defined an element $\epsilon_g(p)$ for every $p \in \mathbb{C}G$). This map ϵ_g is $\mathbb{C}$-linear. We notice some basic properties of these maps:

- For every $g \in G$ and $h \in G$, we have

$$\epsilon_g(h) = \delta_{g,h}. \qquad (13.111.33)$$

[814]

- We have

$$\epsilon_1(pq) = \epsilon_1(qp) \qquad \text{for all } p \in \mathbb{C}G \text{ and } q \in \mathbb{C}G. \qquad (13.111.34)$$

[815]

- We have

$$\epsilon_1\left(g^{-1}q\right) = \epsilon_g(q) \qquad \text{for every } g \in G \text{ and } q \in \mathbb{C}G. \qquad (13.111.35)$$

[816]

Now, for every $(q,u) \in \mathbb{C}G \times U$, we have $\sum\limits_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u \in U^K$ [817]. Hence, we can define a map $\widetilde{\beta} : \mathbb{C}G \times U \to U^K$ by setting

$$\widetilde{\beta}(q,u) = \sum_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u \qquad \text{for every } (q,u) \in \mathbb{C}G \times U.$$

Consider this map $\widetilde{\beta}$. Then, $\widetilde{\beta}$ is a $\mathbb{C}$-bilinear map (because $\widetilde{\beta}(q,u) = \sum_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u$ depends $\mathbb{C}$-linearly on each of q and u). We are now going to prove that the map $\widetilde{\beta}$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U.

In fact, every $h' \in H$, $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\widetilde{\beta}(q,h'u) = \widetilde{\beta}(qh',u). \qquad (13.111.36)$$

[814] This equality has been proven in our solution of Exercise 4.1.4. (Namely, it appeared there as (13.105.3).)

[815] This equality has been proven in our solution of Exercise 4.1.4. (Namely, it appeared there as (13.105.4).)

[816] This equality has been proven in our solution of Exercise 4.1.4. (Namely, it appeared there as (13.105.5).)

[817] *Proof.* Let $(q,u) \in \mathbb{C}G \times U$. Let $x = \sum\limits_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u$. We shall show that $x \in U^K$.

Let $k \in K$. Then, the map $H \to H$, $h \mapsto hk$ is a bijection (since H is a group). Now, multiplying both sides of the equality $x = \sum\limits_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u$ with k from the left, we obtain

$$\begin{aligned} kx &= k\sum_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u = \sum_{h \in H} \epsilon_1(\rho(h)q)kh^{-1}u \\ &= \sum_{h \in H} \epsilon_1\left(\underbrace{\rho(hk)}_{\substack{=\rho(h)\rho(k) \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} q\right) k \underbrace{(hk)^{-1}}_{=k^{-1}h^{-1}} u \qquad \left(\begin{array}{c}\text{here, we substituted } hk \text{ for } h \text{ in the sum,} \\ \text{since the map } H \to H,\ h \mapsto hk \text{ is a bijection}\end{array}\right) \\ &= \sum_{h \in H} \epsilon_1\left(\rho(h) \underbrace{\rho(k)}_{\substack{=1 \\ \text{(since } k \in K = \ker\rho)}} q\right) \underbrace{kk^{-1}}_{=1} h^{-1}u = \sum_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u = x. \end{aligned}$$

Let us now forget that we fixed k. We thus have shown that $kx = x$ for every $k \in K$. In other words, x is an element $y \in U$ satisfying $ky = y$ for every $k \in K$. Hence,

$$x \in \{y \in U \mid ky = y \text{ for every } k \in K\} = U^K.$$

Thus, $\sum\limits_{h \in H} \epsilon_1(\rho(h)q)h^{-1}u = x \in U^K$, qed.

[818] As a consequence of this, we can see that every $r \in \mathbb{C}H$, $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\widetilde{\beta}\left(q, ru\right) = \widetilde{\beta}\left(qr, u\right). \tag{13.111.38}$$

[819] In other words, the map $\widetilde{\beta}$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U (since we already know that $\widetilde{\beta}$ is $\mathbb{C}$-bilinear). Hence, by the universal property of the tensor product, we conclude that there exists a unique $\mathbb{C}$-linear map $\beta : \mathbb{C}G \otimes_{\mathbb{C}H} U \to U^K$ such that every $(q, u) \in \mathbb{C}G \times U$ satisfies

$$\beta\left(q \otimes_{\mathbb{C}H} u\right) = \widetilde{\beta}\left(q, u\right). \tag{13.111.39}$$

Consider this map β. Clearly, every $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\beta\left(q \otimes_{\mathbb{C}H} u\right) = \widetilde{\beta}\left(q, u\right) = \sum_{h \in H} \epsilon_1\left(\rho\left(h\right) q\right) h^{-1} u \qquad \left(\text{by the definition of } \widetilde{\beta}\right). \tag{13.111.40}$$

We shall now show that the maps α and $\dfrac{1}{|K|}\beta$ are mutually inverse. To do so, we will show that $\alpha \circ \beta = |K| \operatorname{id}$ and $\beta \circ \alpha = |K| \operatorname{id}$.

Let us first notice that

$$1 \otimes_{\mathbb{C}H} h^{-1} u = \left(\rho\left(h\right)\right)^{-1} \otimes_{\mathbb{C}H} u \qquad \text{for any } h \in H \text{ and } u \in U. \tag{13.111.41}$$

[820]

[818] *Proof of (13.111.36):* Let $h' \in H$, $q \in \mathbb{C}G$ and $u \in U$. Then, the map $H \to H,\ h \mapsto h'h$ is a bijection (since H is a group). The definition of $\widetilde{\beta}$ yields

$$\begin{aligned}
\widetilde{\beta}\left(q, h'u\right) &= \sum_{h \in H} \epsilon_1\left(\rho\left(h\right) q\right) h^{-1} h' u = \sum_{h \in H} \epsilon_1\left(\underbrace{\rho\left(h'h\right)}_{\substack{=\rho\left(h'\right)\rho\left(h\right) \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} q \right) \underbrace{\left(h'h\right)^{-1}}_{=h^{-1}\left(h'\right)^{-1}} h' u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } h'h \text{ for } h \text{ in the sum,} \\ \text{since the map } H \to H,\ h \mapsto h'h \text{ is a bijection}\end{array}\right) \\
&= \sum_{h \in H} \underbrace{\epsilon_1\left(\rho\left(h'\right)\rho\left(h\right) q\right)}_{\substack{=\epsilon_1\left(\rho\left(h\right) q \rho\left(h'\right)\right) \\ \text{(by (13.111.34), applied to} \\ \rho\left(h'\right) \text{ and } \rho\left(h\right) q \text{ instead of } p \text{ and } q)}} h^{-1} \underbrace{\left(h'\right)^{-1} h'}_{=1} u \\
&= \sum_{h \in H} \epsilon_1\left(\rho\left(h\right) q \rho\left(h'\right)\right) h^{-1} u. \qquad (13.111.37)
\end{aligned}$$

But the definition of the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ yields $\gamma\eta = \gamma \cdot \left(\mathbb{C}\left[\rho\right]\right) \eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$. Applying this to $\gamma = q$ and $\eta = h'$, we obtain $qh' = q \cdot \left(\mathbb{C}\left[\rho\right]\right)\left(h'\right)$. But $h' \in H$ and thus $\left(\mathbb{C}\left[\rho\right]\right)\left(h'\right) = \rho\left(h'\right)$. Hence, $qh' = q \cdot \underbrace{\left(\mathbb{C}\left[\rho\right]\right)\left(h'\right)}_{=\rho\left(h'\right)} = q\rho\left(h'\right)$.

But the definition of $\widetilde{\beta}$ also yields

$$\begin{aligned}
\widetilde{\beta}\left(qh', u\right) &= \sum_{h \in H} \epsilon_1\left(\rho\left(h\right) \underbrace{qh'}_{=q\rho\left(h'\right)} \right) h^{-1} u = \sum_{h \in H} \epsilon_1\left(\rho\left(h\right) q \rho\left(h'\right)\right) h^{-1} u \\
&= \widetilde{\beta}\left(q, h'u\right) \qquad \left(\text{by (13.111.37)}\right).
\end{aligned}$$

In other words, $\widetilde{\beta}\left(q, h'u\right) = \widetilde{\beta}\left(qh', u\right)$. This proves (13.111.36).

[819] *Proof of (13.111.38):* Let $r \in \mathbb{C}H$, $q \in \mathbb{C}G$ and $u \in U$. We need to prove the equality (13.111.38). But this equality is $\mathbb{C}$-linear in r. Hence, we can WLOG assume that r belongs to the basis H of the $\mathbb{C}$-vector space $\mathbb{C}H$. Assume this. Then, (13.111.38) follows from (13.111.36) (applied to $h' = r$).

[820] *Proof of (13.111.41):* Let $h \in H$ and $u \in U$. We have $h \in H$. Since H is a group, this yields $h^{-1} \in H \subset \mathbb{C}H$. Hence, we can move the h^{-1} past the tensor sign in $1 \otimes_{\mathbb{C}H} h^{-1} u$. We thus obtain $1 \otimes_{\mathbb{C}H} h^{-1} u = 1h^{-1} \otimes_{\mathbb{C}H} u$.

But the definition of the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ yields $\gamma\eta = \gamma \cdot \left(\mathbb{C}\left[\rho\right]\right) \eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$. Applying this to $\gamma = 1$ and $\eta = h^{-1}$, we obtain $1h^{-1} = 1 \cdot \left(\mathbb{C}\left[\rho\right]\right)\left(h^{-1}\right)$. But $h^{-1} \in H$ and thus $\left(\mathbb{C}\left[\rho\right]\right)\left(h^{-1}\right) = \rho\left(h^{-1}\right) = \left(\rho\left(h\right)\right)^{-1}$ (since ρ

Now, we are going to show that $\alpha \circ \beta = |K| \operatorname{id}$. In fact, let $q \in \mathbb{C}G$ and $u \in U$ be arbitrary. Then,

$$
\begin{aligned}
(\alpha\circ\beta)\left(q\otimes_{\mathbb{C}H} u\right) &= \alpha\left(\beta\left(q\otimes_{\mathbb{C}H}u\right)\right) = 1\otimes_{\mathbb{C}H} \underbrace{\beta\left(q\otimes_{\mathbb{C}H}u\right)}_{\substack{=\sum_{h\in H}\epsilon_1(\rho(h)q)h^{-1}u \\ \text{(by (13.111.40))}}} \\
&\qquad (\text{by the definition of } \alpha) \\
&= 1\otimes_{\mathbb{C}H}\left(\sum_{h\in H}\epsilon_1\left(\rho\left(h\right)q\right)h^{-1}u\right) = \underbrace{\sum_{h\in H}}_{=\sum_{g\in G}\sum_{\substack{h\in H;\\ \rho(h)=g}}} \epsilon_1\left(\rho\left(h\right)q\right) \underbrace{1\otimes_{\mathbb{C}H}h^{-1}u}_{\substack{=(\rho(h))^{-1}\otimes_{\mathbb{C}H}u\\ \text{(by (13.111.41))}}} \\
&= \sum_{g\in G}\underbrace{\sum_{\substack{h\in H;\\ \rho(h)=g}}}_{=\sum_{h\in\rho^{-1}(g)}} \epsilon_1\left(\underbrace{\rho\left(h\right)}_{=g}q\right)\left(\underbrace{\rho\left(h\right)}_{=g}\right)^{-1}\otimes_{\mathbb{C}H}u = \sum_{g\in G}\underbrace{\sum_{h\in\rho^{-1}(g)}\epsilon_1\left(gq\right)g^{-1}\otimes_{\mathbb{C}H}u}_{=|\rho^{-1}(g)|\epsilon_1(gq)g^{-1}\otimes_{\mathbb{C}H}u} \\
&= \sum_{g\in G}\underbrace{\left|\rho^{-1}\left(g\right)\right|}_{\substack{=|K|\\ \text{(by (13.111.29))}}}\epsilon_1\left(gq\right)g^{-1}\otimes_{\mathbb{C}H}u = \sum_{g\in G}|K|\,\epsilon_1\left(gq\right)g^{-1}\otimes_{\mathbb{C}H}u \\
&= |K|\left(\sum_{g\in G}\epsilon_1\left(gq\right)g^{-1}\right)\otimes_{\mathbb{C}H}u = |K|\left(\sum_{g\in G}\epsilon_1\left(g^{-1}q\right)\underbrace{\left(g^{-1}\right)^{-1}}_{=g}\right)\otimes_{\mathbb{C}H}u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } g^{-1} \text{ for } g \text{ in the sum, since the map}\\ G\to G,\ g\mapsto g^{-1} \text{ is a bijection (since } G \text{ is a group)}\end{array}\right) \\
&= |K|\left(\sum_{g\in G}\underbrace{\epsilon_1\left(g^{-1}q\right)}_{\substack{=\epsilon_g(q)\\ \text{(by (13.111.35))}}}g\right)\otimes_{\mathbb{C}H}u = |K|\underbrace{\left(\sum_{g\in G}\epsilon_g\left(q\right)g\right)}_{\substack{=q\\ \text{(by (13.111.32))}}}\otimes_{\mathbb{C}H}u \\
&= |K|\underbrace{q\otimes_{\mathbb{C}H}u}_{=\operatorname{id}(q\otimes_{\mathbb{C}H}u)} = |K|\operatorname{id}\left(q\otimes_{\mathbb{C}H}u\right).
\end{aligned}
$$

Now, let us forget that we fixed q and u. We thus have shown that $(\alpha\circ\beta)\left(q\otimes_{\mathbb{C}H}u\right) = |K|\operatorname{id}\left(q\otimes_{\mathbb{C}H}u\right)$ for all $q\in\mathbb{C}G$ and $u\in U$. In other words, the two maps $\alpha\circ\beta : \mathbb{C}G\otimes_{\mathbb{C}H}U\to\mathbb{C}G\otimes_{\mathbb{C}H}U$ and $|K|\operatorname{id} : \mathbb{C}G\otimes_{\mathbb{C}H}U\to\mathbb{C}G\otimes_{\mathbb{C}H}U$ are equal to each other on each pure tensor. Since these two maps are $\mathbb{C}$-linear, this yields that these two maps $\alpha\circ\beta : \mathbb{C}G\otimes_{\mathbb{C}H}U\to\mathbb{C}G\otimes_{\mathbb{C}H}U$ and $|K|\operatorname{id} : \mathbb{C}G\otimes_{\mathbb{C}H}U\to\mathbb{C}G\otimes_{\mathbb{C}H}U$ must be identical. In other words, $\alpha\circ\beta = |K|\operatorname{id}$.

Next, we are going to show that $\beta\circ\alpha = |K|\operatorname{id}$.

We first notice that

$$h^{-1}u = \left(\rho\left(h\right)\right)^{-1}u \qquad \text{for every } h\in H \text{ and } u\in U^K. \tag{13.111.42}$$

[821]

is a group homomorphism). Hence, $1h^{-1} = 1\cdot\underbrace{\left(\mathbb{C}\left[\rho\right]\right)\left(h^{-1}\right)}_{=(\rho(h))^{-1}} = 1\cdot\left(\rho\left(h\right)\right)^{-1} = \left(\rho\left(h\right)\right)^{-1}$. Now, $1\otimes_{\mathbb{C}H}h^{-1}u = \underbrace{1h^{-1}}_{=(\rho(h))^{-1}}\otimes_{\mathbb{C}H}u = \left(\rho\left(h\right)\right)^{-1}\otimes_{\mathbb{C}H}u$. This proves (13.111.41).

[821] *Proof of (13.111.42):* Let $h\in H$ and $u\in U^K$. Applying (13.111.30) to h^{-1} and u instead of h and v, we obtain $\rho\left(h^{-1}\right)\cdot u = h^{-1}u$. But ρ is a group homomorphism, and thus we have $\left(\rho\left(h\right)\right)^{-1} = \rho\left(h^{-1}\right)$. Hence, $\underbrace{\left(\rho\left(h\right)\right)^{-1}}_{=\rho(h^{-1})}u = \rho\left(h^{-1}\right)u = \rho\left(h^{-1}\right)\cdot u = h^{-1}u$. This proves (13.111.42).

Let $u \in U^K$. The definition of $\alpha(u)$ yields $\alpha(u) = 1 \otimes_{\mathbb{C}H} u$. Applying the map β to this equality, we obtain

$$\beta(\alpha(u)) = \beta(1 \otimes_{\mathbb{C}H} u) = \underbrace{\sum_{h \in H}}_{= \sum_{g \in G} \sum_{\substack{h \in H;\\ \rho(h) = g}}} \epsilon_1(\rho(h)1) \underbrace{h^{-1}u}_{\substack{= (\rho(h))^{-1}u \\ \text{(by (13.111.42))}}} \qquad \text{(by (13.111.40), applied to } q = 1\text{)}$$

$$= \sum_{g \in G} \underbrace{\sum_{\substack{h \in H;\\ \rho(h) = g}}}_{= \sum_{h \in \rho^{-1}(g)}} \epsilon_1\left(\underbrace{\rho(h)}_{=g} 1\right) \left(\underbrace{\rho(h)}_{=g}\right)^{-1} u = \sum_{g \in G} \underbrace{\sum_{h \in \rho^{-1}(g)} \epsilon_1(g1) g^{-1}u}_{= |\rho^{-1}(g)| \epsilon_1(g1) g^{-1}u}$$

$$= \sum_{g \in G} \underbrace{\left|\rho^{-1}(g)\right|}_{\substack{= |K| \\ \text{(by (13.111.29))}}} \epsilon_1(g1) g^{-1}u = \sum_{g \in G} |K| \epsilon_1(g1) g^{-1}u$$

$$= |K| \sum_{g \in G} \epsilon_1(g1) g^{-1}u = |K| \sum_{g \in G} \epsilon_1\left(g^{-1}1\right) \underbrace{\left(g^{-1}\right)^{-1}}_{=g} u$$

$$\left(\begin{array}{c} \text{here, we substituted } g^{-1} \text{ for } g \text{ in the sum, since the map} \\ G \to G,\ g \mapsto g^{-1} \text{ is a bijection (since } G \text{ is a group)} \end{array}\right)$$

$$= |K| \sum_{g \in G} \underbrace{\epsilon_1\left(g^{-1}1\right)}_{\substack{= \epsilon_g(1) \\ \text{(by (13.111.35), applied to } q=1\text{)}}} gu = |K| \sum_{g \in G} \epsilon_g(1) gu = |K| \underbrace{\left(\sum_{g \in G} \epsilon_g(1) g\right)}_{\substack{=1 \\ \text{(because } 1 = \sum_{g \in G} \epsilon_g(1) g \\ \text{(by (13.111.32), applied to } q=1\text{))}}} u$$

$$= |K| \underbrace{u}_{= \operatorname{id}(u)} = |K| \operatorname{id}(u).$$

In other words, $(\beta \circ \alpha)(u) = |K| \operatorname{id}(u)$ (since $(\beta \circ \alpha)(u) = \beta(\alpha(u))$).

Now, forget that we fixed u. We thus have shown that $(\beta \circ \alpha)(u) = |K| \operatorname{id}(u)$ for every $u \in U^K$. In other words, $\beta \circ \alpha = |K| \operatorname{id}$.

The equalities $\alpha \circ \left(\dfrac{1}{|K|}\beta\right) = \dfrac{1}{|K|} \underbrace{\alpha \circ \beta}_{= |K| \operatorname{id}} = \dfrac{1}{|K|} \cdot |K| \operatorname{id} = \operatorname{id}$ and $\left(\dfrac{1}{|K|}\beta\right) \circ \alpha = \dfrac{1}{|K|} \underbrace{\beta \circ \alpha}_{= |K| \operatorname{id}} = \dfrac{1}{|K|} \cdot |K| \operatorname{id} = \operatorname{id}$ show that the maps α and $\dfrac{1}{|K|}\beta$ are mutually inverse. Hence, the map α is invertible.

Now, we know that the map α is an invertible $\mathbb{C}G$-module homomorphism. Hence, α is a $\mathbb{C}G$-module isomorphism. Therefore, there exists a $\mathbb{C}G$-module isomorphism $U^K \to \mathbb{C}G \otimes_{\mathbb{C}H} U$ (namely, α). Therefore, $U^K \cong \mathbb{C}G \otimes_{\mathbb{C}H} U = \operatorname{Ind}_\rho U$ as $\mathbb{C}G$-modules. This solves Exercise 4.1.14(f).

[*Remark:* There is another solution of Exercise 4.1.14(f), which uses the result of Exercise 4.1.12(b). Yet another solution of Exercise 4.1.14(f) relies on Exercise 4.1.14(i), and will be given after the solution of the latter.]

(g) Let $\alpha \in R_{\mathbb{C}}(H)$ and $\beta \in R_{\mathbb{C}}(G)$. We notice that

$$\text{any two conjugate elements } k \text{ and } k' \text{ of } G \text{ satisfy } \beta(k) = \beta(k') \tag{13.111.43}$$

[822].

[822] *Proof of (13.111.43):* We can apply (13.111.1) to $K = G$ and $f = \beta$. As a consequence, we obtain the following equivalence:

$$(\beta \in R_{\mathbb{C}}(G))$$
$$\iff (\text{any two conjugate elements } k \text{ and } k' \text{ of } G \text{ satisfy } \beta(k) = \beta(k')).$$

Hence, any two conjugate elements k and k' of G satisfy $\beta(k) = \beta(k')$ (because we know that $\beta \in R_{\mathbb{C}}(G)$).

Let us first prove (4.1.17). The definition of $\langle \operatorname{Ind}_\rho \alpha, \beta \rangle_G$ yields

$$\begin{aligned}
\langle \operatorname{Ind}_\rho \alpha, \beta \rangle_G &= \frac{1}{|G|} \sum_{g \in G} \underbrace{\left(\operatorname{Ind}_\rho \alpha\right)(g)}_{\substack{= \frac{1}{|H|} \sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \\ \text{(by the definition of } \operatorname{Ind}_\rho \alpha)}} \beta\left(g^{-1}\right) = \frac{1}{|G|} \sum_{g \in G} \left(\frac{1}{|H|} \sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \right) \beta\left(g^{-1}\right) \\
&= \frac{1}{|G|} \frac{1}{|H|} \underbrace{\sum_{g \in G} \sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = g}}}_{= \sum_{(h,k) \in H \times G} \sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}}} \alpha(h)\, \beta \left(\underbrace{g^{-1}}_{\substack{= \left(k\rho(h)k^{-1}\right)^{-1} \\ \text{(since } g = k\rho(h)k^{-1} \\ \text{(since } k\rho(h)k^{-1} = g))}} \right) \\
&= \frac{1}{|G|} \frac{1}{|H|} \sum_{(h,k) \in H \times G} \sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h)\, \beta\left(\left(k\rho(h)\, k^{-1} \right)^{-1} \right). \qquad (13.111.44)
\end{aligned}$$

However, for every $(h,k) \in H \times G$, we have

$$\sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h)\, \beta\left(\left(k\rho(h)\, k^{-1} \right)^{-1} \right) = \alpha(h) \left(\operatorname{Res}_\rho \beta \right) \left(h^{-1} \right) \qquad (13.111.45)$$

[823]. Thus, (13.111.44) becomes

$$\begin{aligned}\left\langle \operatorname{Ind}_\rho \alpha, \beta \right\rangle_G &= \frac{1}{|G|} \frac{1}{|H|} \underbrace{\sum_{(h,k) \in H \times G}}_{= \sum_{h \in H} \sum_{k \in G}} \underbrace{\sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \beta\left(\left(k\rho(h) k^{-1}\right)^{-1}\right)}_{= \alpha(h) (\operatorname{Res}_\rho \beta)(h^{-1})} \\ &= \frac{1}{|G|} \frac{1}{|H|} \sum_{h \in H} \underbrace{\sum_{k \in G} \alpha(h) (\operatorname{Res}_\rho \beta)\left(h^{-1}\right)}_{= |G| \cdot \alpha(h) (\operatorname{Res}_\rho \beta)(h^{-1})} = \frac{1}{|G|} \frac{1}{|H|} \sum_{h \in H} |G| \cdot \alpha(h) (\operatorname{Res}_\rho \beta)\left(h^{-1}\right) \\ &= \frac{1}{|H|} \sum_{h \in H} \alpha(h) (\operatorname{Res}_\rho \beta)\left(h^{-1}\right).\end{aligned}$$

Compared with

$$\begin{aligned}\left\langle \alpha, \operatorname{Res}_\rho \beta \right\rangle_H &= \frac{1}{|H|} \sum_{g \in H} \alpha(g) (\operatorname{Res}_\rho \beta)\left(g^{-1}\right) \qquad \left(\text{by the definition of } \left\langle \alpha, \operatorname{Res}_\rho \beta \right\rangle_H\right) \\ &= \frac{1}{|H|} \sum_{h \in H} \alpha(h) (\operatorname{Res}_\rho \beta)\left(h^{-1}\right) \\ &\qquad (\text{here, we renamed the summation index } g \text{ as } h),\end{aligned}$$

this yields $\left\langle \operatorname{Ind}_\rho \alpha, \beta \right\rangle_G = \left\langle \alpha, \operatorname{Res}_\rho \beta \right\rangle_H$. Thus, (4.1.17) is proven.

[823] *Proof of (13.111.45):* Fix a $(h,k) \in H \times G$. Thus, $h \in H$ and $k \in G$. Now, there exists only one $g \in G$ such that $k\rho(h)k^{-1} = g$ (namely, $g = k\rho(h)k^{-1}$). Hence, the sum $\sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \beta\left(\left(k\rho(h) k^{-1}\right)^{-1}\right)$ has only one addend. Hence, this sum simplifies as follows:

$$\begin{aligned}&\sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \beta\left(\left(k\rho(h) k^{-1}\right)^{-1}\right) \\ &= \alpha(h) \beta\left(\underbrace{\left(k\rho(h) k^{-1}\right)^{-1}}_{= (k^{-1})^{-1} (\rho(h))^{-1} k^{-1}}\right) = \alpha(h) \beta\left(\underbrace{\left(k^{-1}\right)^{-1}}_{= k} \underbrace{(\rho(h))^{-1}}_{\substack{= \rho(h^{-1}) \\ (\text{since } \rho \text{ is a group} \\ \text{homomorphism})}} k^{-1}\right) = \alpha(h) \beta\left(k\rho\left(h^{-1}\right) k^{-1}\right).\end{aligned} \tag{13.111.46}$$

But $\rho\left(h^{-1}\right)$ and $k\rho\left(h^{-1}\right) k^{-1}$ are two conjugate elements of G. Hence, (13.111.43) (applied to $\rho\left(h^{-1}\right)$ and $k\rho\left(h^{-1}\right) k^{-1}$ instead of k and k') yields $\beta\left(\rho\left(h^{-1}\right)\right) = \beta\left(k\rho\left(h^{-1}\right) k^{-1}\right)$. Thus,

$$\beta\left(\left(k\rho(h) k^{-1}\right)^{-1}\right) = \beta\left(\rho\left(h^{-1}\right)\right) = \underbrace{(\beta \circ \rho)}_{\substack{= \operatorname{Res}_\rho \beta \\ (\text{since } \operatorname{Res}_\rho \beta \text{ is defined as } \beta \circ \rho)}} \left(h^{-1}\right) = (\operatorname{Res}_\rho \beta)\left(h^{-1}\right).$$

Hence, (13.111.46) becomes

$$\sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \beta\left(\left(k\rho(h) k^{-1}\right)^{-1}\right) = \alpha(h) \underbrace{\beta\left(k\rho\left(h^{-1}\right) k^{-1}\right)}_{= (\operatorname{Res}_\rho \beta)(h^{-1})} = \alpha(h) (\operatorname{Res}_\rho \beta)\left(h^{-1}\right).$$

This proves (13.111.45).

Let us now prove (4.1.16). (This proof will be very much similar to the proof of (4.1.17) above, but in a few places even easier.) The definition of $\left(\operatorname{Ind}_\rho \alpha, \beta\right)_G$ yields

$$\begin{aligned}
\left(\operatorname{Ind}_\rho \alpha, \beta\right)_G &= \frac{1}{|G|} \sum_{g \in G} \underbrace{\left(\operatorname{Ind}_\rho \alpha\right)(g)}_{\substack{= \frac{1}{|H|} \sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \\ \text{(by the definition of } \operatorname{Ind}_\rho \alpha)}} \overline{\beta(g)} = \frac{1}{|G|} \sum_{g \in G} \left(\frac{1}{|H|} \sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \right) \overline{\beta(g)} \\
&= \frac{1}{|G|} \frac{1}{|H|} \underbrace{\sum_{g \in G} \sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = g}}}_{= \sum_{(h,k) \in H \times G} \sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}}} \alpha(h) \overline{\beta\left(\underbrace{g}_{\substack{= k\rho(h)k^{-1} \\ \text{(since } k\rho(h)k^{-1} = g)}} \right)} \\
&= \frac{1}{|G|} \frac{1}{|H|} \sum_{(h,k) \in H \times G} \sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \overline{\beta\left(k\rho(h)k^{-1}\right)}. \qquad (13.111.47)
\end{aligned}$$

However, for every $(h,k) \in H \times G$, we have

$$\sum_{\substack{g \in G; \\ k\rho(h)k^{-1} = g}} \alpha(h) \overline{\beta\left(k\rho(h)k^{-1}\right)} = \alpha(h) \overline{\left(\operatorname{Res}_\rho \beta\right)(h)} \tag{13.111.48}$$

[824]. Thus, (13.111.47) becomes

$$\begin{aligned}(\operatorname{Ind}_\rho \alpha, \beta)_G &= \frac{1}{|G|}\frac{1}{|H|} \underbrace{\sum_{(h,k)\in H\times G}}_{=\sum_{h\in H}\sum_{k\in G}} \underbrace{\sum_{\substack{g\in G;\\ k\rho(h)k^{-1}=g}} \alpha(h)\overline{\beta(k\rho(h)k^{-1})}}_{=\alpha(h)\overline{(\operatorname{Res}_\rho \beta)(h)}} \\ &= \frac{1}{|G|}\frac{1}{|H|}\sum_{h\in H}\underbrace{\sum_{k\in G}\alpha(h)\overline{(\operatorname{Res}_\rho\beta)(h)}}_{=|G|\cdot\alpha(h)\overline{(\operatorname{Res}_\rho\beta)(h)}} = \frac{1}{|G|}\frac{1}{|H|}\sum_{h\in H}|G|\cdot\alpha(h)\overline{(\operatorname{Res}_\rho\beta)(h)} \\ &= \frac{1}{|H|}\sum_{h\in H}\alpha(h)\overline{(\operatorname{Res}_\rho\beta)(h)}.\end{aligned}$$

Compared with

$$\begin{aligned}(\alpha, \operatorname{Res}_\rho\beta)_H &= \frac{1}{|H|}\sum_{g\in H}\alpha(g)\overline{(\operatorname{Res}_\rho\beta)(g)} \qquad \left(\text{by the definition of } (\alpha,\operatorname{Res}_\rho\beta)_H\right) \\ &= \frac{1}{|H|}\sum_{h\in H}\alpha(h)\overline{(\operatorname{Res}_\rho\beta)(h)} \\ &\qquad (\text{here, we renamed the summation index } g \text{ as } h),\end{aligned}$$

this yields $(\operatorname{Ind}_\rho\alpha,\beta)_G = (\alpha,\operatorname{Res}_\rho\beta)_H$. Thus, (4.1.16) is proven. The solution of Exercise 4.1.14(g) is thus complete.

(h) Let U be a $\mathbb{C}H$-module, and let V be a $\mathbb{C}G$-module.

Recall that $\operatorname{Ind}_\rho U$ is defined as the $\mathbb{C}G$-module $\mathbb{C}G\otimes_{\mathbb{C}H}U$, where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G,\mathbb{C}H)$-bimodule according to the following rule: The left $\mathbb{C}G$-module structure on $\mathbb{C}G$ is plain multiplication inside $\mathbb{C}G$; the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho]:\mathbb{C}H\to\mathbb{C}G$ (thus, it is explicitly given by $\gamma\eta=\gamma\cdot(\mathbb{C}[\rho])\eta$ for all $\gamma\in\mathbb{C}G$ and $\eta\in\mathbb{C}H$). From now on, we regard $\mathbb{C}G$ as endowed with this $(\mathbb{C}G,\mathbb{C}H)$-bimodule structure.

Now, (4.1.8) (applied to $R=\mathbb{C}H$, $S=\mathbb{C}G$, $A=\mathbb{C}G$, $B=U$ and $C=V$) yields

$$\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G\otimes_{\mathbb{C}H}U,V)\cong\operatorname{Hom}_{\mathbb{C}H}(U,\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G,V)). \tag{13.111.50}$$

We shall now prove that $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G,V)\cong\operatorname{Res}_\rho V$ as left $\mathbb{C}H$-modules.

Indeed, a fundamental fact in abstract algebra says the following: If $\mathfrak{A}$ is a $\mathbb{C}$-algebra, and if $\mathfrak{M}$ is a left $\mathfrak{A}$-module, then there exists a $\mathbb{C}$-vector space isomorphism $\Xi:\operatorname{Hom}_{\mathfrak{A}}(\mathfrak{A},\mathfrak{M})\to\mathfrak{M}$ which satisfies $(\Xi(f)=f(1)$ for every $f\in\operatorname{Hom}_{\mathfrak{A}}(\mathfrak{A},\mathfrak{M}))$. Applying this fact to $\mathfrak{A}=\mathbb{C}G$ and $\mathfrak{M}=V$, we conclude that

[824] *Proof of (13.111.48):* Fix a $(h,k)\in H\times G$. Thus, $h\in H$ and $k\in G$. Now, there exists only one $g\in G$ such that $k\rho(h)k^{-1}=g$ (namely, $g=k\rho(h)k^{-1}$). Hence, the sum $\sum_{\substack{g\in G;\\ k\rho(h)k^{-1}=g}}\alpha(h)\overline{\beta(k\rho(h)k^{-1})}$ has only one addend. Hence, this sum simplifies as follows:

$$\sum_{\substack{g\in G;\\ k\rho(h)k^{-1}=g}}\alpha(h)\overline{\beta(k\rho(h)k^{-1})}=\alpha(h)\overline{\beta(k\rho(h)k^{-1})}. \tag{13.111.49}$$

But $\rho(h)$ and $k\rho(h)k^{-1}$ are two conjugate elements of G. Hence, (13.111.43) (applied to $\rho(h)$ and $k\rho(h)k^{-1}$ instead of k and k') yields $\beta(\rho(h))=\beta\left(k\rho(h)k^{-1}\right)$. Thus,

$$\beta\left(k\rho(h)k^{-1}\right)=\beta(\rho(h))=\underbrace{(\beta\circ\rho)}_{\substack{=\operatorname{Res}_\rho\beta\\ (\text{since } \operatorname{Res}_\rho\beta \text{ is defined as } \beta\circ\rho)}}(h)=(\operatorname{Res}_\rho\beta)(h).$$

Hence, (13.111.49) becomes

$$\sum_{\substack{g\in G;\\ k\rho(h)k^{-1}=g}}\alpha(h)\overline{\beta(k\rho(h)k^{-1})}=\alpha(h)\underbrace{\overline{\beta(k\rho(h)k^{-1})}}_{\substack{=\overline{(\operatorname{Res}_\rho\beta)(h)}\\ (\text{since } \beta\left(k\rho(h)k^{-1}\right)=(\operatorname{Res}_\rho\beta)(h))}}=\alpha(h)\overline{(\operatorname{Res}_\rho\beta)(h)}.$$

This proves (13.111.48).

there exists a $\mathbb{C}$-vector space isomorphism $\Xi : \operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V) \to V$ which satisfies $(\Xi(f) = f(1)$ for every $f \in \operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V))$. Consider this Ξ.

The map Ξ is a homomorphism of H-sets from $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ to $\operatorname{Res}_\rho V$ [825]. Therefore, Ξ is a $\mathbb{C}H$-module homomorphism from $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ to $\operatorname{Res}_\rho V$ (since Ξ is a $\mathbb{C}$-linear map). Consequently, Ξ is a $\mathbb{C}H$-module isomorphism from $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ to $\operatorname{Res}_\rho V$ (since Ξ is a $\mathbb{C}$-vector space isomorphism). Therefore, $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V) \cong \operatorname{Res}_\rho V$ as $\mathbb{C}H$-modules. Now,

$$\begin{aligned}
\operatorname{Hom}_{\mathbb{C}G}\left(\underbrace{\operatorname{Ind}_\rho U}_{=\mathbb{C}G\otimes_{\mathbb{C}H}U}, V\right) &= \operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G \otimes_{\mathbb{C}H} U, V) \\
&\cong \operatorname{Hom}_{\mathbb{C}H}\left(U, \underbrace{\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)}_{\cong \operatorname{Res}_\rho V \text{ as } \mathbb{C}H\text{-modules}}\right) \qquad (\text{by } (13.111.50)) \\
&\cong \operatorname{Hom}_{\mathbb{C}H}(U, \operatorname{Res}_\rho V).
\end{aligned}$$

This solves Exercise 4.1.14(h).

(i) The following solution will mostly be an imitation of the solution of Exercise 4.1.4.

Let U be any $\mathbb{C}H$-module. Recall that $\operatorname{Ind}_\rho U$ is defined as the $\mathbb{C}G$-module $\mathbb{C}G \otimes_{\mathbb{C}H} U$, where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}H)$-bimodule according to the following rule: The left $\mathbb{C}G$-module structure on $\mathbb{C}G$ is plain multiplication inside $\mathbb{C}G$; the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho] : \mathbb{C}H \to \mathbb{C}G$ (thus, it is explicitly given by $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho])\eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$). From now on, we regard $\mathbb{C}G$ as endowed with this $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure (besides the $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure that was introduced in the statement of Exercise 4.1.14(i)).

The $\mathbb{C}$-vector space $\mathbb{C}G$ is thus endowed with a left $\mathbb{C}H$-module structure (which is part of the $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure) and with a right $\mathbb{C}H$-module structure (which is part of the $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure). These two structures, combined, form a $(\mathbb{C}H, \mathbb{C}H)$-bimodule structure[826]. This allows us to write expressions like xyz with $x \in \mathbb{C}H$, $y \in \mathbb{C}G$ and $z \in \mathbb{C}H$, without having to disambiguate whether they mean $(xy)z$ or $x(yz)$.

We recall that $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ is the left $\mathbb{C}G$-module consisting of all left $\mathbb{C}H$-module homomorphisms from $\mathbb{C}G$ to U. This uses only the $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure on $\mathbb{C}G$ that was introduced in the statement of Exercise 4.1.14(i) (but not the $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure on $\mathbb{C}G$ that was introduced in the definition of $\operatorname{Ind}_\rho U$).

[825] *Proof.* The map Ξ is clearly a map from $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ to V, therefore a map from $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ to $\operatorname{Res}_\rho V$ (since $\operatorname{Res}_\rho V = V$ as sets).

Recall that the $\mathbb{C}H$-module structure on $\operatorname{Res}_\rho V$ is given by

$$h \cdot v = \rho(h) \cdot v \qquad \text{for every } h \in H \text{ and } v \in V. \tag{13.111.51}$$

Now, let $f \in \operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ and $h \in H$. We are going to prove that $\Xi(h \cdot f) = h \cdot \Xi(f)$, where $h \cdot \Xi(f)$ is computed in the $\mathbb{C}H$-module $\operatorname{Res}_\rho V$.

Indeed, the definition of the left $\mathbb{C}H$-module structure on $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ yields $(\eta \cdot \alpha)(p) = \alpha(p\eta)$ for every $\eta \in \mathbb{C}H$, $\alpha \in \operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ and $p \in \mathbb{C}G$. Applying this to $\eta = h$, $\alpha = f$ and $p = 1$, we obtain $(h \cdot f)(1) = f(1h)$ (since $h \in H \subset \mathbb{C}H$). But the definition of Ξ yields $\Xi(h \cdot f) = (h \cdot f)(1) = f(1h)$.

Recall that the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is given by the equality $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho])\eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$. Applying this equality to $\gamma = 1$ and $\eta = h$, we obtain $1h = 1 \cdot (\mathbb{C}[\rho])(h)$ (since $h \in H \subset \mathbb{C}H$). But $h \in H$ and thus $(\mathbb{C}[\rho])(h) = \rho(h)$. Thus, $1h = 1 \cdot (\mathbb{C}[\rho])(h) = (\mathbb{C}[\rho])(h) = \rho(h) = \rho(h) \cdot 1$. Now, $\Xi(h \cdot f) = f\left(\underbrace{1h}_{=\rho(h)\cdot 1}\right) = f(\rho(h) \cdot 1) = \rho(h) \cdot f(1)$ (since f is a $\mathbb{C}G$-module homomorphism (because $f \in \operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$) and since $\rho(h) \in G \subset \mathbb{C}G$).

On the other hand, (13.111.51) (applied to $v = f(1)$) yields $h \cdot f(1) = \rho(h) \cdot f(1)$. Compared with $\Xi(h \cdot f) = \rho(h) \cdot f(1)$, this yields $\Xi(h \cdot f) = h \cdot f(1)$.

But the definition of Ξ yields $\Xi(f) = f(1)$. Thus, $f(1) = \Xi(f)$, so that $\Xi(h \cdot f) = h \cdot \underbrace{f(1)}_{=\Xi(f)} = h \cdot \Xi(f)$.

Now, let us forget that we fixed f and h. We thus have shown that $\Xi(h \cdot f) = h \cdot \Xi(f)$ for every $f \in \operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ and $h \in H$. In other words, Ξ is a homomorphism of H-sets from $\operatorname{Hom}_{\mathbb{C}G}(\mathbb{C}G, V)$ to $\operatorname{Res}_\rho V$, qed.

[826] This is easy to check (we leave the details of this verification to the reader).

Recall that the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is given by

$$\gamma\eta = \gamma \cdot \left(\mathbb{C}\left[\rho\right]\right)\eta \qquad \text{for all } \gamma \in \mathbb{C}G \text{ and } \eta \in \mathbb{C}H. \tag{13.111.52}$$

For every $\gamma \in \mathbb{C}G$ and $\eta \in H$, we have

$$\begin{aligned} \gamma\eta &= \gamma \cdot \underbrace{\left(\mathbb{C}\left[\rho\right]\right)\eta}_{\substack{=\rho(\eta) \\ (\text{since } \eta\in H)}} \qquad (\text{by (13.111.52) (since } \eta \in H \subset \mathbb{C}H)) \\ &= \gamma \cdot \rho\left(\eta\right). \end{aligned} \tag{13.111.53}$$

On the other hand, the left $\mathbb{C}H$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}\left[\rho\right] : \mathbb{C}H \to \mathbb{C}G$. In other words, this structure is given by

$$\eta\gamma = \left(\mathbb{C}\left[\rho\right]\right)\eta \cdot \gamma \qquad \text{for all } \gamma \in \mathbb{C}G \text{ and } \eta \in \mathbb{C}H. \tag{13.111.54}$$

For every $\gamma \in \mathbb{C}G$ and $\eta \in H$, we have

$$\begin{aligned} \eta\gamma &= \underbrace{\left(\mathbb{C}\left[\rho\right]\right)\eta}_{\substack{=\rho(\eta) \\ (\text{since } \eta\in H)}} \cdot\gamma \qquad (\text{by (13.111.54) (since } \eta \in H \subset \mathbb{C}H)) \\ &= \rho\left(\eta\right)\cdot\gamma. \end{aligned} \tag{13.111.55}$$

The map ρ is a group homomorphism. Hence, $\rho\left(H\right)$ is a subgroup of G. Let us denote this subgroup by $\overline{H}$. Thus, $\overline{H} = \rho\left(H\right)$.

Let J be a system of distinct representatives for the right $\overline{H}$-cosets in G. Then, $G = \bigsqcup_{j\in J} \overline{H}j$.

For every $g \in G$, define a map $\mathfrak{R}_g : J \to J$ as follows: Let $i \in J$. Then, $ig \in G = \bigsqcup_{j\in J} \overline{H}j$. Thus, there exists a unique $j \in J$ such that $ig \in \overline{H}j$. Define $\mathfrak{R}_g\left(i\right)$ to be this j. Hence, we have defined $\mathfrak{R}_g\left(i\right)$ for every $i \in J$. Thus, we have defined a map $\mathfrak{R}_g : J \to J$.

For every $g \in G$ and $i \in J$, we have

$$ig \in \overline{H} \cdot \mathfrak{R}_g\left(i\right) \tag{13.111.56}$$

(because $\mathfrak{R}_g\left(i\right)$ is defined as the $j \in J$ satisfying $ig \in \overline{H}j$).

It is easy to see that for every $g \in G$, the map $\mathfrak{R}_g : J \to J$ is a bijection.[827] We have

$$j^{-1} \otimes_{\mathbb{C}H} f\left(jg\right) = g \cdot \left(\mathfrak{R}_g\left(j\right)\right)^{-1} \otimes_{\mathbb{C}H} f\left(\mathfrak{R}_g\left(j\right)\right) \qquad \text{in } \mathbb{C}G \otimes_{\mathbb{C}H} U \tag{13.111.58}$$

[827] *Proof.* Fix $g \in G$.

The sets $\overline{H}j$ for all $j \in J$ are disjoint (since $\bigsqcup_{j\in J} \overline{H}j$ is well-defined). In other words, if i and i' are two elements of J such that $\overline{H}i$ and $\overline{H}i'$ are not disjoint, then

$$i = i'. \tag{13.111.57}$$

Let us now prove that $\mathfrak{R}_g$ is injective.

Let i and i' be two elements of J. Assume that $\mathfrak{R}_g\left(i\right) = \mathfrak{R}_g\left(i'\right)$. We will show that $i = i'$.

From (13.111.56), we have $ig \in \overline{H} \cdot \mathfrak{R}_g\left(i\right)$. Hence, there exists some $h \in \overline{H}$ such that $ig = h \cdot \mathfrak{R}_g\left(i\right)$. Consider this h. We have

$$\overline{H} \underbrace{ig}_{=h\cdot\mathfrak{R}_g(i)} = \underbrace{\overline{H}h}_{\substack{=\overline{H} \\ (\text{since } h\in\overline{H} \text{ and since} \\ \overline{H} \text{ is a group})}} \cdot\mathfrak{R}_g\left(i\right) = \overline{H}\cdot\mathfrak{R}_g\left(i\right).$$

The same argument (but for i' instead of i) yields $\overline{H}i'g = \overline{H}\cdot\mathfrak{R}_g\left(i'\right)$. Hence, $\overline{H}ig = \overline{H}\cdot\underbrace{\mathfrak{R}_g\left(i\right)}_{=\mathfrak{R}_g(i')} = \overline{H}\cdot\mathfrak{R}_g\left(i'\right) = \overline{H}i'g$. Thus, $\underbrace{\overline{H}ig}_{=\overline{H}i'g} g^{-1} = \overline{H}i'gg^{-1} = \overline{H}i'$, so that $\overline{H}i' = \overline{H}igg^{-1} = \overline{H}i$. Thus, the sets $\overline{H}i$ and $\overline{H}i'$ are not disjoint (because $\left(\overline{H}i\right) \cap \underbrace{\left(\overline{H}i'\right)}_{=\overline{H}i} = \left(\overline{H}i\right) \cap \left(\overline{H}i\right) = \overline{H}i \neq \varnothing$). Therefore, $i = i'$ (by (13.111.57)).

Now, forget that we fixed i and i'. We thus have shown that if i and i' are two elements of J such that $\mathfrak{R}_g\left(i\right) = \mathfrak{R}_g\left(i'\right)$, then $i = i'$. In other words, the map $\mathfrak{R}_g$ is injective. But the set J is finite (since it is a subset of the finite set G). Hence, $\mathfrak{R}_g$ is a map from a finite set (namely, J) to itself. Since we know that $\mathfrak{R}_g$ is injective, this yields that $\mathfrak{R}_g$ is surjective (because any injective map from a finite set to itself must be surjective). Hence, $\mathfrak{R}_g$ is bijective (since $\mathfrak{R}_g$ is injective and surjective), that is, a bijection, qed.

for every $g \in G$, every $j \in J$ and every $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. [828]

We now define a map $\alpha : \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \to \mathbb{C}G \otimes_{\mathbb{C}H} U$ by setting

$$\alpha(f) = \sum_{j \in J} j^{-1} \otimes_{\mathbb{C}H} f(j) \qquad \text{for all } f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U).$$

This α is a map $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \to \operatorname{Ind}_\rho U$ (since $\operatorname{Ind}_\rho U = \mathbb{C}G \otimes_{\mathbb{C}H} U$).

We will show that α is a $\mathbb{C}G$-module isomorphism.

First, let us prove that α is a left $\mathbb{C}G$-module homomorphism. In fact, any $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ and $g \in G$ satisfy

$$\begin{aligned}
\alpha(gf) &= \sum_{j \in J} j^{-1} \otimes_{\mathbb{C}H} \underbrace{(gf)(j)}_{\substack{=f(jg) \\ \text{(by the definition of } gf)}} \qquad (\text{by the definition of } \alpha(gf)) \\
&= \sum_{j \in J} \underbrace{j^{-1} \otimes_{\mathbb{C}H} f(jg)}_{\substack{= g \cdot (\mathfrak{R}_g(j))^{-1} \otimes_{\mathbb{C}H} f(\mathfrak{R}_g(j)) \\ \text{(by (13.111.58))}}} = \sum_{j \in J} g \cdot (\mathfrak{R}_g(j))^{-1} \otimes_{\mathbb{C}H} f(\mathfrak{R}_g(j)) = \sum_{j \in J} g \cdot j^{-1} \otimes_{\mathbb{C}H} f(j) \\
&\qquad \left(\begin{array}{c} \text{here, we have substituted } j \text{ for } \mathfrak{R}_g(j) \text{ in the sum, since} \\ \text{the map } \mathfrak{R}_g : J \to J \text{ is a bijection} \end{array}\right) \\
&= g \cdot \underbrace{\sum_{j \in J} j^{-1} \otimes_{\mathbb{C}H} f(j)}_{=\alpha(f)} = g \cdot \alpha(f).
\end{aligned}$$

The map α is thus a homomorphism of left G-sets. Since α is furthermore $\mathbb{C}$-linear, this yields that α is a left $\mathbb{C}G$-module homomorphism.

We now are going to construct an inverse for α. This will be more cumbersome.

For every $g \in G$ and every $p \in \mathbb{C}G$, we denote by $\epsilon_g(p)$ the g-coordinate of p with respect to the basis G of the $\mathbb{C}$-vector space $\mathbb{C}G$. By the definition of "coordinate", we have

$$q = \sum_{g \in G} \epsilon_g(q) g \qquad \text{for every } q \in \mathbb{C}G. \tag{13.111.60}$$

For every $g \in G$, we have defined a map $\epsilon_g : \mathbb{C}G \to \mathbb{C}$ (because we have defined an element $\epsilon_g(p)$ for every $p \in \mathbb{C}G$). This map ϵ_g is $\mathbb{C}$-linear. We record some properties of these maps:

[828] *Proof of (13.111.58):* Let $g \in G$, $j \in J$ and $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. Applying (13.111.56) to $i = j$, we obtain $jg \in \overline{H} \cdot \mathfrak{R}_g(j)$. In other words, there exists an $h \in \overline{H}$ such that $jg = h \cdot \mathfrak{R}_g(j)$. Consider this h. We have

$$j^{-1} \underbrace{jg}_{=h \cdot \mathfrak{R}_g(j)} \cdot (\mathfrak{R}_g(j))^{-1} = j^{-1} h \cdot \underbrace{\mathfrak{R}_g(j) \cdot (\mathfrak{R}_g(j))^{-1}}_{=1} = j^{-1} h,$$

hence

$$j^{-1} h = j^{-1} jg \cdot (\mathfrak{R}_g(j))^{-1} = g \cdot (\mathfrak{R}_g(j))^{-1}.$$

But $h \in \overline{H} = \rho(H)$. Hence, there exists a $h' \in H$ such that $h = \rho(h')$. Consider this h'.

Applying (13.111.55) to $\eta = h'$ and $\gamma = \mathfrak{R}_g(j)$, we obtain $h' \cdot \mathfrak{R}_g(j) = \underbrace{\rho(h')}_{=h} \cdot \mathfrak{R}_g(j) = h \cdot \mathfrak{R}_g(j) = jg$ (since $jg = h \cdot \mathfrak{R}_g(j)$).

But the map f is left $\mathbb{C}H$-linear (since $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$). Thus, $f(h' \cdot \mathfrak{R}_g(j)) = h' \cdot f(\mathfrak{R}_g(j))$ (since $h' \in H \subset \mathbb{C}H$). Since $h' \cdot \mathfrak{R}_g(j) = jg$, this rewrites as $f(jg) = h' \cdot f(\mathfrak{R}_g(j))$. Hence,

$$j^{-1} \otimes_{\mathbb{C}H} \underbrace{f(jg)}_{=h' \cdot f(\mathfrak{R}_g(j))} = j^{-1} \otimes_{\mathbb{C}H} h' \cdot f(\mathfrak{R}_g(j)) = j^{-1} h' \otimes_{\mathbb{C}H} f(\mathfrak{R}_g(j)) \tag{13.111.59}$$

(here, we have moved h' past the $\otimes_{\mathbb{C}H}$ sign, since $h' \in H \subset \mathbb{C}H$).

On the other hand, applying (13.111.53) to $\gamma = j^{-1}$ and $\eta = h'$, we obtain $j^{-1} h' = j^{-1} \cdot \underbrace{\rho(h')}_{=h} = j^{-1} h = g \cdot (\mathfrak{R}_g(j))^{-1}$.

Hence, (13.111.59) becomes

$$j^{-1} \otimes_{\mathbb{C}H} f(jg) = \underbrace{j^{-1} h'}_{=g \cdot (\mathfrak{R}_g(j))^{-1}} \otimes_{\mathbb{C}H} f(\mathfrak{R}_g(j)) = g \cdot (\mathfrak{R}_g(j))^{-1} \otimes_{\mathbb{C}H} f(\mathfrak{R}_g(j)).$$

This proves (13.111.58).

- For every $g \in G$ and $h \in G$, we have

$$\epsilon_g(h) = \delta_{g,h}. \tag{13.111.61}$$

[829]

- We have

$$\epsilon_1(pq) = \epsilon_1(qp) \qquad \text{for all } p \in \mathbb{C}G \text{ and } q \in \mathbb{C}G. \tag{13.111.62}$$

[830]

- We have

$$\epsilon_1\left(g^{-1}q\right) = \epsilon_g(q) \qquad \text{for every } g \in G \text{ and } q \in \mathbb{C}G. \tag{13.111.63}$$

[831]

Now, fix $q \in \mathbb{C}G$ and $u \in U$. We let $f_{q,u}$ be the map $\mathbb{C}G \to U$ defined by

$$f_{q,u}(p) = \sum_{h\in H} \epsilon_1(\rho(h)pq)h^{-1}u \qquad \text{for every } p \in \mathbb{C}G. \tag{13.111.64}$$

It is obvious that this map $f_{q,u}$ is $\mathbb{C}$-linear. We will show that $f_{q,u}$ is a left $\mathbb{C}H$-module homomorphism.

The map $f_{q,u}$ is a homomorphism of left H-sets[832]. Since $f_{q,u}$ is furthermore $\mathbb{C}$-linear, this yields that $f_{q,u}$ is a left $\mathbb{C}H$-module homomorphism. Hence, $f_{q,u} \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$.

Now, forget that we fixed q and u. We thus have defined a map $f_{q,u} \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ for every $q \in \mathbb{C}G$ and $u \in U$. It is easy to see that this map $f_{q,u}$ depends $\mathbb{C}$-linearly on each of q and u. Now, define a map $\widetilde{\beta} : \mathbb{C}G \times U \to \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ by

$$\widetilde{\beta}(q,u) = f_{q,u} \qquad \text{for every } (q,u) \in \mathbb{C}G \times U.$$

[829] This equality has been proven in our solution of Exercise 4.1.4. (Namely, it appeared there as (13.105.3).)

[830] This equality has been proven in our solution of Exercise 4.1.4. (Namely, it appeared there as (13.105.4).)

[831] This equality has been proven in our solution of Exercise 4.1.4. (Namely, it appeared there as (13.105.5).)

[832] *Proof.* In fact, for every $h' \in H$ and every $p \in \mathbb{C}G$, we have

$$f_{q,u}(h'p) = \sum_{h\in H} \epsilon_1\left(\rho(h) \underbrace{(h'p)}_{\substack{=\rho(h')\cdot p \\ (\text{by (13.111.55), applied} \\ \text{to } \gamma=p \text{ and } \eta=h')}} q\right) h^{-1}u \qquad (\text{by the definition of } f_{q,u})$$

$$= \sum_{h\in H} \epsilon_1(\rho(h)\rho(h')\cdot pq)h^{-1}u = \sum_{h\in H} \epsilon_1\left(\underbrace{\rho\left(h(h')^{-1}\right)}_{\substack{=\rho(h)(\rho(h'))^{-1} \\ (\text{since } \rho \text{ is a group} \\ \text{homomorphism})}} \rho(h')\cdot pq\right) \underbrace{\left(h(h')^{-1}\right)^{-1}}_{=((h')^{-1})^{-1}h^{-1}=h'h^{-1}} u$$

$$\left(\begin{array}{c}\text{here, we have substituted } h(h')^{-1} \text{ for } h \text{ in the sum,} \\ \text{because the map } H \to H,\ h \mapsto h(h')^{-1} \text{ is a bijection} \\ (\text{since } H \text{ is a group and since } h' \in H)\end{array}\right)$$

$$= \sum_{h\in H} \epsilon_1\left(\rho(h) \underbrace{(\rho(h'))^{-1}\rho(h')}_{=1} \cdot pq\right) h'h^{-1}u$$

$$= \sum_{h\in H} \epsilon_1(\rho(h)pq)h'h^{-1}u = h' \cdot \underbrace{\sum_{h\in H} \epsilon_1(\rho(h)pq)h^{-1}u}_{\substack{=f_{q,u}(p) \\ (\text{by (13.111.64)})}} = h' \cdot f_{q,u}(p).$$

In other words, $f_{q,u}$ is a homomorphism of left H-sets, qed.

Then, $\widetilde{\beta}$ is a $\mathbb{C}$-bilinear map (because $\widetilde{\beta}(q,u) = f_{q,u}$ depends $\mathbb{C}$-linearly on each of q and u). We are now going to prove that the map $\widetilde{\beta}$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U.

In fact, every $h' \in H$, $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\widetilde{\beta}(q, h'u) = \widetilde{\beta}(qh', u). \tag{13.111.65}$$

[833] As a consequence of this, we can see that every $r \in \mathbb{C}H$, $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\widetilde{\beta}(q, ru) = \widetilde{\beta}(qr, u). \tag{13.111.67}$$

[834] In other words, the map $\widetilde{\beta}$ is $\mathbb{C}H$-bilinear with respect to the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ and the left $\mathbb{C}H$-module structure on U (since we already know that $\widetilde{\beta}$ is $\mathbb{C}$-bilinear). Hence, by the universal property of the tensor product, we conclude that there exists a unique $\mathbb{C}$-linear map $\beta : \mathbb{C}G \otimes_{\mathbb{C}H} U \to \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ such that every $(q,u) \in \mathbb{C}G \times U$ satisfies

$$\beta(q \otimes_{\mathbb{C}H} u) = \widetilde{\beta}(q,u). \tag{13.111.68}$$

Consider this map β. Clearly, every $q \in \mathbb{C}G$ and $u \in U$ satisfy

$$\beta(q \otimes_{\mathbb{C}H} u) = \widetilde{\beta}(q,u) = f_{q,u} \qquad \left(\text{by the definition of } \widetilde{\beta}\right).$$

[833] *Proof of (13.111.65):* Let $h' \in H$, $q \in \mathbb{C}G$ and $u \in U$. Then, the map $H \to H,\ h \mapsto h'h$ is a bijection (since H is a group). Now, let $p \in \mathbb{C}G$. The definition of $\widetilde{\beta}$ yields $\widetilde{\beta}(q,h'u) = f_{q,h'u}$. Hence,

$$\begin{aligned}
\Bigl(\underbrace{\widetilde{\beta}(q,h'u)}_{=f_{q,h'u}}\Bigr)(p) &= f_{q,h'u}(p) = \sum_{h\in H} \epsilon_1(\rho(h)pq)\,h^{-1}h'u \qquad \left(\text{by the definition of } f_{q,h'u}\right) \\
&= \sum_{h\in H} \epsilon_1\Bigl(\underbrace{\rho(h'h)}_{\substack{=\rho(h')\rho(h) \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} pq\Bigr) \underbrace{(h'h)^{-1}}_{=h^{-1}(h')^{-1}} h'u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } h'h \text{ for } h \text{ in the sum,} \\ \text{since the map } H \to H,\ h \mapsto h'h \text{ is a bijection}\end{array}\right) \\
&= \sum_{h\in H} \underbrace{\epsilon_1(\rho(h')\rho(h)pq)}_{\substack{=\epsilon_1(\rho(h)pq\rho(h')) \\ \text{(by (13.111.62), applied to} \\ \rho(h') \text{ and } \rho(h)pq \text{ instead of } p \text{ and } q)}} h^{-1} \underbrace{(h')^{-1}h'}_{=1} u \\
&= \sum_{h\in H} \epsilon_1(\rho(h)pq\rho(h'))\,h^{-1}u. \qquad\qquad (13.111.66)
\end{aligned}$$

But the definition of $\widetilde{\beta}$ also yields $\widetilde{\beta}(qh',u) = f_{qh',u}$. Hence,

$$\begin{aligned}
\left(\widetilde{\beta}(qh',u)\right)(p) &= f_{qh',u}(p) = \sum_{h\in H} \epsilon_1\Bigl(\rho(h)p \underbrace{(qh')}_{\substack{=q\cdot\rho(h') \\ \text{(by (13.111.53), applied to} \\ \gamma=q \text{ and } \eta=h')}}\Bigr) h^{-1}u \qquad \left(\text{by the definition of } f_{qh',u}\right) \\
&= \sum_{h\in H} \epsilon_1(\rho(h)pq\cdot\rho(h'))\,h^{-1}u = \sum_{h\in H} \epsilon_1(\rho(h)pq\rho(h'))\,h^{-1}u = \left(\widetilde{\beta}(q,h'u)\right)(p) \qquad (\text{by (13.111.66)}).
\end{aligned}$$

Now, forget that we fixed p. We have thus proven that $\left(\widetilde{\beta}(qh',u)\right)(p) = \left(\widetilde{\beta}(q,h'u)\right)(p)$ for every $p \in \mathbb{C}G$. In other words, $\widetilde{\beta}(qh',u) = \widetilde{\beta}(q,h'u)$, so that $\widetilde{\beta}(q,h'u) = \widetilde{\beta}(qh',u)$. This proves (13.111.65).

[834] *Proof of (13.111.67):* Let $r \in \mathbb{C}H$, $q \in \mathbb{C}G$ and $u \in U$. We need to prove the equality (13.111.67). But this equality is $\mathbb{C}$-linear in r. Hence, we can WLOG assume that r belongs to the basis H of the $\mathbb{C}$-vector space $\mathbb{C}H$. Assume this. Then, (13.111.67) follows from (13.111.65) (applied to $h' = r$).

Hence, every $q \in \mathbb{C}G$, $u \in U$ and $p \in \mathbb{C}G$ satisfy

$$(13.111.69) \qquad \Bigg(\underbrace{\beta\left(q \otimes_{\mathbb{C}H} u\right)}_{=f_{q,u}}\Bigg)(p) = f_{q,u}(p) = \sum_{h \in H} \epsilon_1\left(\rho(h)\, pq\right) h^{-1} u$$

(by (13.111.64)).

Let $K = \ker \rho$. Thus, K is the kernel of a group homomorphism out of H (since ρ is a group homomorphism out of H), and therefore a normal subgroup of H.

We notice that

$$(13.111.70) \qquad \left|\rho^{-1}(g)\right| = |K| \qquad \text{for every } g \in \overline{H}.$$

[835]

We shall now show that the maps α and $\dfrac{1}{|K|}\beta$ are mutually inverse. To do so, we will show that $\alpha \circ \beta = |K| \operatorname{id}$ and $\beta \circ \alpha = |K| \operatorname{id}$.

[835] *Proof of (13.111.70):* Let $g \in \overline{H}$. Then, $g \in \overline{H} = \rho(H)$. Hence, $g = \rho(x)$ for some $x \in H$. Let us fix such a x.

We know that H is a group. Hence, the map $K \to xK$, $k \mapsto xk$ is a bijection. Thus, the sets K and xK are in bijection. Therefore, $|xK| = |K|$.

However, for every $y \in H$, we have the following logical equivalence:

$$\left(y \in \rho^{-1}(g)\right) \iff \Bigg(\rho(y) = \underbrace{g}_{=\rho(x)}\Bigg) \iff \left(\rho(y) = \rho(x)\right) \iff \Bigg(\underbrace{\rho(y) \cdot \left(\rho(x)\right)^{-1}}_{\substack{=\rho\left(yx^{-1}\right) \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} = 1\Bigg)$$
$$\iff \left(\rho\left(yx^{-1}\right) = 1\right) \iff \Bigg(yx^{-1} \in \underbrace{\ker \rho}_{=K}\Bigg) \iff \left(yx^{-1} \in K\right) \iff \left(y \in xK\right).$$

Hence, $\rho^{-1}(g) = xK$, so that $\left|\rho^{-1}(g)\right| = |xK| = |K|$. This proves (13.111.70).

Let us first show that $\alpha \circ \beta = \mathrm{id}$. In fact, let $q \in \mathbb{C}G$ and $u \in U$ be arbitrary. Then,

$$\begin{aligned}
\left(\alpha \circ \beta\right)\left(q \otimes_{\mathbb{C}H} u\right) &= \alpha\left(\beta\left(q \otimes_{\mathbb{C}H} u\right)\right) = \sum_{j \in J} j^{-1} \otimes_{\mathbb{C}H} \underbrace{\left(\beta\left(q \otimes_{\mathbb{C}H} u\right)\right)(j)}_{\substack{=\sum\limits_{h\in H} \epsilon_1(\rho(h)jq)h^{-1}u \\ \text{(by (13.111.69), applied to } p=j\text{)}}} \\
&\qquad \text{(by the definition of } \alpha\text{)} \\
&= \sum_{j \in J} j^{-1} \otimes_{\mathbb{C}H} \left(\sum_{h \in H} \epsilon_1\left(\rho\left(h\right) jq\right) h^{-1} u\right) = \sum_{j \in J} \sum_{h \in H} \epsilon_1\left(\rho\left(h\right) jq\right) \underbrace{j^{-1} \otimes_{\mathbb{C}H} h^{-1} u}_{\substack{=j^{-1}h^{-1} \otimes_{\mathbb{C}H} u \\ \text{(since } h^{-1} \in \mathbb{C}H \text{ (since } h \in H \\ \text{and thus } h^{-1} \in H \subset \mathbb{C}H\text{))}}} \\
&= \sum_{j \in J} \sum_{h \in H} \epsilon_1\left(\rho\left(h\right) jq\right) \underbrace{j^{-1} h^{-1}}_{\substack{=j^{-1} \cdot \rho\left(h^{-1}\right) \\ \text{(by (13.111.53), applied to } \gamma=j^{-1} \\ \text{and } \eta=h^{-1} \text{ (since } h^{-1} \in H \text{ (since } h \in H\text{)))}}} \otimes_{\mathbb{C}H} u \\
&= \sum_{j \in J} \underbrace{\sum_{h \in H}}_{\substack{=\sum_{g \in \overline{H}} \sum\limits_{\substack{h \in H; \\ \rho(h)=g}} \\ \text{(since every } h \in H \text{ satisfies} \\ \rho(h) \in \rho(H) = \overline{H}\text{)}}} \epsilon_1\left(\rho\left(h\right) jq\right) j^{-1} \cdot \underbrace{\rho\left(h^{-1}\right)}_{\substack{=(\rho(h))^{-1} \\ \text{(since } \rho \text{ is a group} \\ \text{homomorphism)}}} \otimes_{\mathbb{C}H} u \\
&= \sum_{j \in J} \sum_{g \in \overline{H}} \underbrace{\sum_{\substack{h \in H; \\ \rho(h)=g}}}_{=\sum_{h \in \rho^{-1}(g)}} \epsilon_1\left(\underbrace{\rho\left(h\right)}_{=g} jq\right) j^{-1} \cdot \left(\underbrace{\rho\left(h\right)}_{=g}\right)^{-1} \otimes_{\mathbb{C}H} u \\
&= \sum_{j \in J} \sum_{g \in \overline{H}} \underbrace{\sum_{h \in \rho^{-1}(g)} \epsilon_1\left(gjq\right) j^{-1} \cdot g^{-1} \otimes_{\mathbb{C}H} u}_{=\left|\rho^{-1}(g)\right| \cdot \epsilon_1(gjq) j^{-1} \cdot g^{-1} \otimes_{\mathbb{C}H} u} \\
&= \sum_{j \in J} \sum_{g \in \overline{H}} \underbrace{\left|\rho^{-1}\left(g\right)\right|}_{\substack{=|K| \\ \text{(by (13.111.70))}}} \cdot \epsilon_1\left(gjq\right) \underbrace{j^{-1} \cdot g^{-1}}_{=(gj)^{-1}} \otimes_{\mathbb{C}H} u
\end{aligned}$$

$$
\begin{aligned}
&= \sum_{j\in J}\sum_{g\in\overline{H}} |K|\cdot\epsilon_1(gjq)(gj)^{-1}\otimes_{\mathbb{C}H} u = |K|\cdot\sum_{j\in J}\sum_{g\in\overline{H}}\epsilon_1(gjq)(gj)^{-1}\otimes_{\mathbb{C}H} u \\
&= |K|\cdot \underbrace{\sum_{j\in J}\sum_{g\in\overline{H}j}}_{\substack{=\sum_{g\in G}\\ (\text{since } \bigsqcup_{j\in J}\overline{H}j=G)}} \epsilon_1(gq)g^{-1}\otimes_{\mathbb{C}H} u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } g \text{ for } gj \text{ in the second sum, since the map}\\ \overline{H}\to\overline{H}j,\ g\mapsto gj \text{ is a bijection (because } G \text{ is a group)}\end{array}\right)\\
&= |K|\cdot\sum_{g\in G}\epsilon_1(gq)g^{-1}\otimes_{\mathbb{C}H} u = |K|\cdot\sum_{g\in G}\underbrace{\epsilon_1\left(g^{-1}q\right)}_{\substack{=\epsilon_g(q)\\ (\text{by (13.111.63)})}}\underbrace{\left(g^{-1}\right)^{-1}}_{=g}\otimes_{\mathbb{C}H} u \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } g^{-1} \text{ for } g \text{ in the sum, since the map}\\ G\to G,\ g\mapsto g^{-1} \text{ is a bijection (since } G \text{ is a group)}\end{array}\right)\\
&= |K|\cdot\sum_{g\in G}\epsilon_g(q)g\otimes_{\mathbb{C}H} u = |K|\cdot\underbrace{\left(\sum_{g\in G}\epsilon_g(q)g\right)}_{\substack{=q\\ (\text{by (13.111.60)})}}\otimes_{\mathbb{C}H} u \\
&= |K|\cdot\underbrace{q\otimes_{\mathbb{C}H} u}_{=\mathrm{id}(q\otimes_{\mathbb{C}H} u)} = |K|\cdot\mathrm{id}(q\otimes_{\mathbb{C}H} u) = (|K|\,\mathrm{id})(q\otimes_{\mathbb{C}H} u).
\end{aligned}
$$

Now, let us forget that we fixed q and u. We thus have shown that $(\alpha\circ\beta)(q\otimes_{\mathbb{C}H} u) = (|K|\,\mathrm{id})(q\otimes_{\mathbb{C}H} u)$ for all $q\in\mathbb{C}G$ and $u\in U$. In other words, the two maps $\alpha\circ\beta : \mathbb{C}G\otimes_{\mathbb{C}H} U\to\mathbb{C}G\otimes_{\mathbb{C}H} U$ and $|K|\,\mathrm{id} : \mathbb{C}G\otimes_{\mathbb{C}H} U\to\mathbb{C}G\otimes_{\mathbb{C}H} U$ are equal to each other on each pure tensor. Since these two maps are $\mathbb{C}$-linear, this yields that these two maps $\alpha\circ\beta : \mathbb{C}G\otimes_{\mathbb{C}H} U\to\mathbb{C}G\otimes_{\mathbb{C}H} U$ and $|K|\,\mathrm{id} : \mathbb{C}G\otimes_{\mathbb{C}H} U\to\mathbb{C}G\otimes_{\mathbb{C}H} U$ must be identical. In other words, $\alpha\circ\beta = |K|\,\mathrm{id}$.

Next, we are going to show that $\beta\circ\alpha = |K|\,\mathrm{id}$.

Let $f\in\mathrm{Hom}_{\mathbb{C}H}(\mathbb{C}G,U)$. Let $p\in\mathbb{C}G$. The map f is left $\mathbb{C}H$-linear (since $f\in\mathrm{Hom}_{\mathbb{C}H}(\mathbb{C}G,U)$), hence $\mathbb{C}$-linear. We have $\alpha(f) = \sum_{j\in J} j^{-1}\otimes_{\mathbb{C}H} f(j)$ (by the definition of α). Applying the map β to this equality, we obtain

$$\beta(\alpha(f)) = \beta\left(\sum_{j\in J} j^{-1}\otimes_{\mathbb{C}H} f(j)\right) = \sum_{j\in J}\beta\left(j^{-1}\otimes_{\mathbb{C}H} f(j)\right)$$

(since β is a $\mathbb{C}$-linear map). Thus,

$$\begin{aligned}
&\underbrace{\left(\beta\left(\alpha\left(f\right)\right)\right)}_{=\sum_{j\in J}\beta\left(j^{-1}\otimes_{\mathbb{C}H}f(j)\right)}\left(p\right) \\
&=\left(\sum_{j\in J}\beta\left(j^{-1}\otimes_{\mathbb{C}H}f\left(j\right)\right)\right)\left(p\right)=\sum_{j\in J}\underbrace{\left(\beta\left(j^{-1}\otimes_{\mathbb{C}H}f\left(j\right)\right)\right)\left(p\right)}_{\substack{=\sum\limits_{h\in H}\epsilon_1\left(\rho(h)pj^{-1}\right)h^{-1}f(j)\\ \text{(by (13.111.69), applied to}\\ q=j^{-1}\text{ and }u=f(j))}} \\
&=\sum_{j\in J}\sum_{h\in H}\epsilon_1\left(\rho\left(h\right)pj^{-1}\right)h^{-1}f\left(j\right)=\sum_{j\in J}\sum_{h\in H}\underbrace{\epsilon_1\left(\rho\left(h^{-1}\right)pj^{-1}\right)}_{\substack{=\epsilon_1\left(j^{-1}\rho\left(h^{-1}\right)p\right)\\ \text{(by (13.111.62), applied to}\\ \rho\left(h^{-1}\right)p\text{ and }j^{-1}\text{ instead of }p\text{ and }q)}}\underbrace{\left(h^{-1}\right)^{-1}}_{=h}f\left(j\right) \\
&\qquad\left(\begin{array}{c}\text{here, we substituted }h^{-1}\text{ for }h\text{ in the second sum,}\\ \text{since the map }H\to H,\ h\mapsto h^{-1}\text{ is a bijection}\\ \text{(because }H\text{ is a group)}\end{array}\right) \\
&=\sum_{j\in J}\sum_{h\in H}\epsilon_1\left(j^{-1}\underbrace{\rho\left(h^{-1}\right)}_{\substack{=(\rho(h))^{-1}\\ \text{(since }\rho\text{ is a group}\\ \text{homomorphism)}}}p\right)\underbrace{hf\left(j\right)}_{\substack{=f(hj)\\ \text{(since }f\text{ is left }\mathbb{C}H\text{-linear and since }h\in H\subset\mathbb{C}H)}} \\
&=\sum_{j\in J}\sum_{h\in H}\epsilon_1\left(\underbrace{j^{-1}\left(\rho\left(h\right)\right)^{-1}}_{=(\rho(h)j)^{-1}}p\right)f\left(\underbrace{hj}_{\substack{=\rho(h)\cdot j\\ \text{(by (13.111.55), applied to}\\ \eta=h\text{ and }\gamma=j)}}\right) \\
&=\sum_{j\in J}\underbrace{\sum_{h\in H}}_{\substack{=\sum_{g\in\overline{H}}\sum\limits_{\substack{h\in H;\\ \rho(h)=g}}\\ \text{(since every }h\in H\text{ satisfies}\\ \rho(h)\in\rho(H)=\overline{H})}}\epsilon_1\left(\left(\rho\left(h\right)j\right)^{-1}p\right)f\left(\rho\left(h\right)j\right) \\
&=\sum_{j\in J}\sum_{g\in\overline{H}}\underbrace{\sum_{\substack{h\in H;\\ \rho(h)=g}}}_{=\sum_{h\in\rho^{-1}(g)}}\epsilon_1\left(\left(\underbrace{\rho\left(h\right)}_{=g}j\right)^{-1}p\right)f\left(\underbrace{\rho\left(h\right)}_{=g}j\right)=\sum_{j\in J}\sum_{g\in\overline{H}}\underbrace{\sum_{h\in\rho^{-1}(g)}\epsilon_1\left(\left(gj\right)^{-1}p\right)f\left(gj\right)}_{=\left|\rho^{-1}(g)\right|\cdot\epsilon_1\left((gj)^{-1}p\right)f(gj)} \\
&=\sum_{j\in J}\sum_{g\in\overline{H}}\underbrace{\left|\rho^{-1}\left(g\right)\right|}_{\substack{=|K|\\ \text{(by (13.111.70))}}}\cdot\epsilon_1\left(\left(gj\right)^{-1}p\right)f\left(gj\right)=\sum_{j\in J}\sum_{g\in\overline{H}}\left|K\right|\cdot\epsilon_1\left(\left(gj\right)^{-1}p\right)f\left(gj\right)
\end{aligned}$$

$$= |K| \cdot \sum_{j\in J} \sum_{g\in \overline{H}} \epsilon_1 \left((gj)^{-1} p \right) f(gj) = |K| \cdot \underbrace{\sum_{j\in J} \sum_{g\in \overline{H}j}}_{\substack{= \sum_{g\in G} \\ (\text{since } \bigsqcup_{j\in J} \overline{H}j = G)}} \epsilon_1 \left(g^{-1} p \right) f(g)$$

$$\left(\begin{array}{c} \text{here, we substituted } g \text{ for } gj \text{ in the second sum, since the map} \\ \overline{H} \to \overline{H}j,\ g \mapsto gj \text{ is a bijection (because } G \text{ is a group)} \end{array} \right)$$

$$= |K| \cdot \sum_{g\in G} \underbrace{\epsilon_1 \left(g^{-1} p \right)}_{\substack{= \epsilon_g(p) \\ (\text{by (13.111.63), applied to } q=p)}} f(g) = |K| \cdot \underbrace{\sum_{g\in G} \epsilon_g(p) f(g)}_{\substack{= f\left(\sum_{g\in G} \epsilon_g(p) g \right) \\ (\text{since } f \text{ is } \mathbb{C}\text{-linear})}} = |K| \cdot f\left(\sum_{g\in G} \epsilon_g(p) g \right).$$

Compared with

$$(|K| f)(p) = |K| \cdot f \left(\underbrace{p}_{\substack{= \sum_{g\in G} \epsilon_g(p) g \\ (\text{by (13.111.60), applied to } q=p)}} \right) = |K| \cdot f \left(\sum_{g\in G} \epsilon_g(p) g \right),$$

this yields $(\beta(\alpha(f)))(p) = (|K| f)(p)$.

Now, forget that we fixed p. We thus have proven that $(\beta(\alpha(f)))(p) = (|K| f)(p)$ for every $p \in \mathbb{C}G$. In other words, $\beta(\alpha(f)) = |K| f$. Hence, $(\beta \circ \alpha)(f) = \beta(\alpha(f)) = |K| f = (|K| \operatorname{id})(f)$.

Now, forget that we fixed f. We thus have shown that $(\beta \circ \alpha)(f) = (|K| \operatorname{id})(f)$ for every $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. In other words, $\beta \circ \alpha = |K| \operatorname{id}$.

We now have $\beta \circ \alpha = |K| \operatorname{id}$ and thus $\left(\dfrac{1}{|K|} \beta \right) \circ \alpha = \dfrac{1}{|K|} \underbrace{(\beta \circ \alpha)}_{= |K| \operatorname{id}} = \dfrac{1}{|K|} |K| \operatorname{id} = \operatorname{id}$.

On the other hand, recall that $\alpha \circ \beta = |K| \operatorname{id}$. Hence, $\alpha \circ \left(\dfrac{1}{|K|} \beta \right) = \dfrac{1}{|K|} \underbrace{(\alpha \circ \beta)}_{= |K| \operatorname{id}} = \dfrac{1}{|K|} |K| \operatorname{id} = \operatorname{id}$.

Combining the equalities $\left(\dfrac{1}{|K|} \beta \right) \circ \alpha = \operatorname{id}$ and $\alpha \circ \left(\dfrac{1}{|K|} \beta \right) = \operatorname{id}$, we conclude that the maps α and $\dfrac{1}{|K|} \beta$ are mutually inverse. Hence, the map α is invertible.

Now, we know that the map α is an invertible left $\mathbb{C}G$-module homomorphism. Hence, α is a left $\mathbb{C}G$-module isomorphism. Therefore, there exists a left $\mathbb{C}G$-module isomorphism $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \to \mathbb{C}G \otimes_{\mathbb{C}H} U$ (namely, α). Therefore, $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \cong \mathbb{C}G \otimes_{\mathbb{C}H} U = \operatorname{Ind}_\rho U$ as left $\mathbb{C}G$-modules. This solves Exercise 4.1.14(i).

[*Remark:* In our above solution of Exercise 4.1.14(i), we explicitly constructed a $\mathbb{C}G$-module isomorphism $\alpha : \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \to \operatorname{Ind}_\rho U$. This isomorphism is functorial with respect to U. It is also independent on the choice of J (this is not immediately clear from its definition, but it can be shown very easily, by observing that the tensor $j^{-1} \otimes_{\mathbb{C}H} f(j)$ for $j \in G$ depends only on the coset $\overline{H}j$ and not on j itself).]

[*Remark:* Exercise 4.1.14(i) allows us to give yet another solution to Exercise 4.1.14(f):

Second solution to Exercise 4.1.14(f): Assume that $G = H/K$ for some normal subgroup K of H. Let $\rho : H \to G$ be the projection map. We want to prove that $\operatorname{Ind}_\rho U \cong U^K$ for every $\mathbb{C}H$-module U.

We know that ρ is the projection map from H to H/K. Hence, ρ is a surjective group homomorphism and has kernel $\ker \rho = K$.

Let U be a $\mathbb{C}H$-module. Recall that U^K is a $\mathbb{C}[H/K]$-module, thus a $\mathbb{C}G$-module (since $H/K = G$). This $\mathbb{C}G$-module structure has the property that

$$\rho(h) \cdot v = hv \qquad \text{for any } h \in H \text{ and } v \in U^K. \tag{13.111.71}$$

[836]

Let us make $\mathbb{C}G$ into a $(\mathbb{C}H, \mathbb{C}G)$-bimodule as in Exercise 4.1.14(i). From now on, we regard $\mathbb{C}G$ as endowed with this $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure. Then, the $\mathbb{C}G$-module $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ (defined as in Exercise 4.1.4 using the $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure on $\mathbb{C}G$) is isomorphic to $\operatorname{Ind}_\rho U$ (because of Exercise 4.1.14(i)). In other words, $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \cong \operatorname{Ind}_\rho U$ as left $\mathbb{C}G$-modules.

We recall that $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ is the left $\mathbb{C}G$-module consisting of all left $\mathbb{C}H$-module homomorphisms from $\mathbb{C}G$ to U. This uses only the $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure on $\mathbb{C}G$ that was introduced in the statement of Exercise 4.1.14(i) (but not the $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure on $\mathbb{C}G$ that was introduced in the definition of $\operatorname{Ind}_\rho U$).

We have $f(1) \in U^K$ for every $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ [837]. Thus, we can define a map $\phi : \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \to U^K$ by

$$(\phi(f) = f(1) \qquad \text{for all } f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)).$$

[836] *Proof of (13.111.71):* The proof of (13.111.71) is identical with the proof of (13.111.30) in the First solution to Exercise 4.1.14(f).

[837] *Proof.* Let $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. Let $k \in K$. Thus, $k \in K = \ker \rho$, so that $\rho(k) = 1_G$.

But $k \in K \subset H$. Thus, (13.111.55) (applied to $\gamma = 1_{\mathbb{C}G}$ and $\eta = k$) yields $k 1_{\mathbb{C}G} = \underbrace{\rho(k)}_{=1_G} 1_{\mathbb{C}G} = 1_G 1_{\mathbb{C}G} = 1_G$.

But $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. Hence, the map f is left $\mathbb{C}H$-linear. Thus, $f(k 1_{\mathbb{C}G}) = kf(1_{\mathbb{C}G})$ (since $k \in H \subset \mathbb{C}H$). Since $k 1_{\mathbb{C}G} = 1_G$, this rewrites as $f(1_G) = kf\left(\underbrace{1_{\mathbb{C}G}}_{=1}\right) = kf(1)$, so that $kf(1) = f\left(\underbrace{1_G}_{=1}\right) = f(1)$.

Now, let us forget that we fixed k. We thus have shown that $kf(1) = f(1)$ for every $k \in K$. In other words, $f(1)$ is an element y of U which satisfies $ky = y$ for every $k \in K$. In other words,

$$f(1) \in \{y \in U \mid ky = y \text{ for every } k \in K\} = U^K,$$

qed.

Consider this ϕ. This map ϕ is clearly $\mathbb{C}$-linear (since $f(1)$ depends $\mathbb{C}$-linearly on f). Also, the map ϕ is surjective[838] and injective[839]. Hence, the map ϕ is bijective. Thus, ϕ is a $\mathbb{C}$-vector space isomorphism (since ϕ is $\mathbb{C}$-linear).

Moreover, ϕ is a homomorphism of left G-sets[840], and therefore a left $\mathbb{C}G$-module homomorphism (since f is $\mathbb{C}$-linear). Thus, ϕ is a left $\mathbb{C}G$-module isomorphism (since ϕ is a $\mathbb{C}$-vector space isomorphism). We thus have found a left $\mathbb{C}G$-module isomorphism from $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ to U^K (namely, ϕ). Hence, $U^K \cong \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ as left $\mathbb{C}G$-modules. Hence, $U^K \cong \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U) \cong \operatorname{Ind}_\rho U$ as left $\mathbb{C}G$-modules. This solves Exercise 4.1.14(f) again.]

(j) Let U be a $\mathbb{C}G$-module, and let V be a $\mathbb{C}H$-module.

[838] *Proof.* Let $u \in U^K$. We are going to construct a map $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ which satisfies $\phi(f) = u$.

Indeed, let us define a map $f : \mathbb{C}G \to U$ by

$$(f(\gamma) = \gamma u \qquad \text{for every } \gamma \in \mathbb{C}G). \tag{13.111.72}$$

(This is well-defined, since U^K is a $\mathbb{C}G$-module.) This map f is $\mathbb{C}$-linear (since γu depends $\mathbb{C}$-linearly on γ). We shall now check that the map f is a homomorphism of left H-sets.

Indeed, let $h \in H$ and $\gamma \in \mathbb{C}G$. We have $f(h\gamma) = (h\gamma)u$ (by the definition of f).

On the other hand, (13.111.55) (applied to $\eta = h$) yields $h\gamma = \rho(h) \cdot \gamma$.

But $u \in U^K$ and therefore $\gamma u \in U^K$ (since $\gamma \in \mathbb{C}G$ and since U^K is a $\mathbb{C}G$-module). Thus, (13.111.71) (applied to γu instead of v) yields $\rho(h) \cdot (\gamma u) = h(\gamma u)$. Now,

$$f(h\gamma) = \underbrace{(h\gamma)}_{=\rho(h)\cdot\gamma} u = (\rho(h)\cdot\gamma)u = \rho(h)\cdot(\gamma u) = h \underbrace{(\gamma u)}_{\substack{=f(\gamma) \\ (\text{by } (13.111.72))}} = hf(\gamma).$$

Now, let us forget that we fixed h and γ. We thus have proven that $f(h\gamma) = hf(\gamma)$ for all $h \in H$ and $\gamma \in \mathbb{C}G$. In other words, f is a homomorphism of left H-sets. Hence, f is a left $\mathbb{C}H$-module homomorphism (since f is $\mathbb{C}$-linear). In other words, $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. Now, the definition of ϕ yields

$$\begin{aligned} \phi(f) = f(1) &= 1u \qquad (\text{by } (13.111.72), \text{ applied to } \gamma = 1) \\ &= u. \end{aligned}$$

Thus, $u = \phi\left(\underbrace{f}_{\in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G,U)}\right) \in \phi(\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))$.

Let us now forget that we fixed u. We thus have shown that $u \in \phi(\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))$ for every $u \in U^K$. In other words, $U^K \subset \phi(\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U))$. This proves that the map ϕ is surjective. Qed.

[839] *Proof.* Let $f \in \ker\phi$. Then, $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ and $\phi(f) = 0$ (since $f \in \ker\phi$). The definition of ϕ yields $\phi(f) = f\left(\underbrace{1}_{=1_{\mathbb{C}G}}\right) = f(1_{\mathbb{C}G})$, so that $f(1_{\mathbb{C}G}) = \phi(f) = 0$.

Now, let $g \in G$ be arbitrary. Then, there exists some $h \in H$ such that $g = \rho(h)$ (since ρ is surjective). Consider this h. Applying (13.111.55) to $\gamma = 1_{\mathbb{C}G}$ and $\eta = h$, we obtain $h1_{\mathbb{C}G} = \rho(h) \cdot 1_{\mathbb{C}G} = \rho(h) = g$. But the map f is left $\mathbb{C}H$-linear (since $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$). Thus, $f(h1_{\mathbb{C}G}) = hf(1_{\mathbb{C}G})$ (since $h \in H \subset \mathbb{C}H$), so that $f(h1_{\mathbb{C}G}) = h\underbrace{f(1_{\mathbb{C}G})}_{=0} = 0$. Compared with $f\left(\underbrace{h1_{\mathbb{C}G}}_{=g}\right) = f(g)$, this yields $f(g) = 0$.

Now, let us forget that we fixed g. Thus, we have shown that $f(g) = 0$ for every $g \in G$. In other words, the map f sends every element of the basis G of the $\mathbb{C}$-vector space $\mathbb{C}G$ to 0. Hence, $f = 0$ (since the map f is $\mathbb{C}$-linear).

Now, let us forget that we fixed f. We thus have shown that $f = 0$ for every $f \in \ker\phi$. In other words, $\ker\phi = 0$. Since ϕ is a $\mathbb{C}$-linear map, this shows that ϕ is injective. Qed.

[840] *Proof.* Let $g \in G$ and $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. The definition of the left $\mathbb{C}G$-module structure on $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$ yields

$$(gf)(1) = f\left(\underbrace{1g}_{=g}\right) = f(g).$$

Now, the definition of ϕ yields $\phi(gf) = (gf)(1) = f(g)$.

But there exists some $h \in H$ such that $g = \rho(h)$ (since ρ is surjective). Consider this h. The map f is left $\mathbb{C}H$-linear (since $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$). Thus, we have $f(h1_{\mathbb{C}G}) = hf(1_{\mathbb{C}G})$. But (13.111.55) (applied to $\gamma = 1_{\mathbb{C}G}$ and $\eta = h$) yields $h1_{\mathbb{C}G} = \underbrace{\rho(h)}_{=g} \cdot 1_{\mathbb{C}G} = g \cdot 1_{\mathbb{C}G} = g$, so that $g = h1_{\mathbb{C}G}$. Hence, $f\left(\underbrace{g}_{=h1_{\mathbb{C}G}}\right) = f(h1_{\mathbb{C}G}) = hf(1_{\mathbb{C}G})$.

Let us make $\mathbb{C}G$ into a $(\mathbb{C}H, \mathbb{C}G)$-bimodule as in Exercise 4.1.14(i). From now on, we regard $\mathbb{C}G$ as endowed with this $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure. Then, the $\mathbb{C}G$-module $\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)$ (defined as in Exercise 4.1.4 using the $(\mathbb{C}H, \mathbb{C}G)$-bimodule structure on $\mathbb{C}G$) is isomorphic to $\operatorname{Ind}_\rho V$ (because of Exercise 4.1.14(i), applied to V instead of U). In other words,

$$\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V) \cong \operatorname{Ind}_\rho V \qquad \text{as left } \mathbb{C}G\text{-modules.} \tag{13.111.73}$$

Now, (4.1.8) (applied to $R = \mathbb{C}G$, $S = \mathbb{C}H$, $A = \mathbb{C}G$, $B = U$ and $C = V$) yields

$$\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G \otimes_{\mathbb{C}G} U, V) \cong \operatorname{Hom}_{\mathbb{C}G}(U, \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)). \tag{13.111.74}$$

We shall now prove that $\mathbb{C}G \otimes_{\mathbb{C}G} U \cong \operatorname{Res}_\rho U$ as left $\mathbb{C}H$-modules.

Indeed, a fundamental fact in abstract algebra says the following: If $\mathfrak{A}$ is a $\mathbb{C}$-algebra, and if $\mathfrak{M}$ is a left $\mathfrak{A}$-module, then there exists a $\mathbb{C}$-vector space isomorphism $\Xi : \mathfrak{A} \otimes_{\mathfrak{A}} \mathfrak{M} \to \mathfrak{M}$ which satisfies $(\Xi(a \otimes_{\mathfrak{A}} m) = am$ for every $a \in \mathfrak{A}$ and $m \in \mathfrak{M})$. Applying this fact to $\mathfrak{A} = \mathbb{C}G$ and $\mathfrak{M} = U$, we conclude that there exists a $\mathbb{C}$-vector space isomorphism $\Xi : \mathbb{C}G \otimes_{\mathbb{C}G} U \to U$ which satisfies
$(\Xi(a \otimes_{\mathbb{C}G} m) = am$ for every $a \in \mathbb{C}G$ and $m \in U)$. Consider this Ξ.

The map Ξ is a $\mathbb{C}$-vector space isomorphism. Hence, its inverse Ξ^{-1} exists and also is a $\mathbb{C}$-vector space isomorphism, and therefore a $\mathbb{C}$-linear map. It furthermore satisfies

$$\Xi^{-1}(u) = 1 \otimes_{\mathbb{C}G} u \qquad \text{for every } u \in U. \tag{13.111.75}$$

[841]

The map Ξ^{-1} is a homomorphism of H-sets from $\operatorname{Res}_\rho U$ to $\mathbb{C}G \otimes_{\mathbb{C}G} U$ [842]. Therefore, Ξ^{-1} is a $\mathbb{C}H$-module homomorphism from $\operatorname{Res}_\rho U$ to $\mathbb{C}G \otimes_{\mathbb{C}G} U$ (since Ξ^{-1} is a $\mathbb{C}$-linear map). Consequently, Ξ^{-1} is a

The definition of ϕ yields $\phi(f) = f\left(\underbrace{1}_{=1_{\mathbb{C}G}}\right) = f(1_{\mathbb{C}G})$, so that $f(1_{\mathbb{C}G}) = \phi(f)$. Now, $f(g) = h\underbrace{f(1_{\mathbb{C}G})}_{=\phi(f)} = h\phi(f)$. Hence,

$$\phi(gf) = f(g) = h\phi(f).$$

The equality (13.111.71) (applied to $\phi(f)$ instead of v) yields $\rho(h) \cdot \phi(f) = h\phi(f)$. Thus, $h\phi(f) = \underbrace{\rho(h)}_{=g} \cdot \phi(f) = g \cdot \phi(f) = g\phi(f)$. Hence, $\phi(gf) = h\phi(f) = g\phi(f)$.

Now, let us forget that we fixed g and f. We thus have proven that $\phi(gf) = g\phi(f)$ for all $g \in G$ and $f \in \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, U)$. In other words, the map ϕ is a homomorphism of left G-sets. Qed.

[841] *Proof of (13.111.75):* Let $u \in U$. Recall that $\Xi(a \otimes_{\mathbb{C}G} m) = am$ for every $a \in \mathbb{C}G$ and $m \in U$. Applying this to $a = 1$ and $m = u$, we obtain $\Xi(1 \otimes_{\mathbb{C}G} u) = 1u = u$. Hence, $1 \otimes_{\mathbb{C}G} u = \Xi^{-1}(u)$ (since Ξ is invertible). This proves (13.111.75).

[842] *Proof.* The map Ξ^{-1} is a map from U to $\mathbb{C}G \otimes_{\mathbb{C}G} U$, therefore a map from $\operatorname{Res}_\rho U$ to $\mathbb{C}G \otimes_{\mathbb{C}G} U$ (since $\operatorname{Res}_\rho U = U$ as sets).

Recall that the $\mathbb{C}H$-module structure on $\operatorname{Res}_\rho U$ is given by

$$h \cdot v = \rho(h) \cdot v \qquad \text{for every } h \in H \text{ and } v \in U. \tag{13.111.76}$$

Now, let $v \in \operatorname{Res}_\rho U$ and $h \in H$. We are going to prove that $\Xi^{-1}(h \cdot v) = h \cdot \Xi^{-1}(v)$, where $h \cdot \Xi^{-1}(v)$ is computed in the $\mathbb{C}H$-module $\mathbb{C}G \otimes_{\mathbb{C}G} U$.

Indeed, recall that the left $\mathbb{C}H$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho] : \mathbb{C}H \to \mathbb{C}G$. Thus, it is explicitly given by

$$\eta\gamma = (\mathbb{C}[\rho])\,\eta \cdot \gamma \qquad \text{for all } \gamma \in \mathbb{C}G \text{ and } \eta \in \mathbb{C}H.$$

Applying this to $\eta = h$ and $\gamma = 1_{\mathbb{C}G}$, we obtain $h1_{\mathbb{C}G} = (\mathbb{C}[\rho])(h) \cdot 1_{\mathbb{C}G}$ (since $h \in H \subset \mathbb{C}H$). But $h \in H$ and thus $(\mathbb{C}[\rho])(h) = \rho(h)$. Hence, $h1_{\mathbb{C}G} = \underbrace{(\mathbb{C}[\rho])(h)}_{=\rho(h)} \cdot 1_{\mathbb{C}G} = \rho(h) \cdot 1_{\mathbb{C}G} = \rho(h) = 1_{\mathbb{C}G} \cdot \rho(h)$. Now, $v \in \operatorname{Res}_\rho U = U$. Hence, (13.111.75) (applied to $u = v$) yields $\Xi^{-1}(v) = 1 \otimes_{\mathbb{C}G} v$. Thus,

$$\begin{aligned}
h \cdot \underbrace{\Xi^{-1}(v)}_{=1 \otimes_{\mathbb{C}G} v} &= h \cdot (1 \otimes_{\mathbb{C}G} v) = h \underbrace{1}_{=1_{\mathbb{C}G}} \otimes_{\mathbb{C}G} v = \underbrace{h1_{\mathbb{C}G}}_{=1_{\mathbb{C}G} \cdot \rho(h)} \otimes_{\mathbb{C}G} v = 1_{\mathbb{C}G} \cdot \rho(h) \otimes_{\mathbb{C}G} v \\
&= \underbrace{1_{\mathbb{C}G}}_{=1} \otimes_{\mathbb{C}G} \underbrace{\rho(h) \cdot v}_{\substack{=h \cdot v \\ \text{(by (13.111.76))}}} \qquad \left(\begin{array}{c}\text{here, we have moved } \rho(h) \text{ past the tensor sign} \\ \text{(this is allowed since } \rho(h) \in G \subset \mathbb{C}G)\end{array}\right) \\
&= 1 \otimes_{\mathbb{C}G} h \cdot v.
\end{aligned}$$

Compared with $\Xi^{-1}(h \cdot v) = 1 \otimes_{\mathbb{C}G} h \cdot v$ (by (13.111.75), applied to $u = h \cdot v$), this yields $\Xi^{-1}(h \cdot v) = h \cdot \Xi^{-1}(v)$.

Now, let us forget that we fixed v and h. We thus have shown that $\Xi^{-1}(h \cdot v) = h \cdot \Xi^{-1}(v)$ for every $v \in \operatorname{Res}_\rho U$ and $h \in H$. In other words, Ξ^{-1} is a homomorphism of H-sets from $\operatorname{Res}_\rho U$ to $\mathbb{C}G \otimes_{\mathbb{C}G} U$, qed.

$\mathbb{C}H$-module isomorphism from $\operatorname{Res}_\rho U$ to $\mathbb{C}G \otimes_{\mathbb{C}G} U$ (since Ξ^{-1} is a $\mathbb{C}$-vector space isomorphism). Therefore, $\mathbb{C}G \otimes_{\mathbb{C}G} U \cong \operatorname{Res}_\rho U$ as $\mathbb{C}H$-modules. Now, (4.1.8) (applied to $\mathbb{C}G$, $\mathbb{C}H$, $\mathbb{C}G$, U and V instead of R, S, A, B and C) yields

$$\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G \otimes_{\mathbb{C}G} U, V) \cong \operatorname{Hom}_{\mathbb{C}G}(U, \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)).$$

Thus,

$$\begin{aligned}\operatorname{Hom}_{\mathbb{C}G}(U, \operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)) &\cong \operatorname{Hom}_{\mathbb{C}H}\left(\underbrace{\mathbb{C}G \otimes_{\mathbb{C}G} U}_{\cong \operatorname{Res}_\rho U \text{ as } \mathbb{C}H\text{-modules}}, V\right) \\ &\cong \operatorname{Hom}_{\mathbb{C}H}(\operatorname{Res}_\rho U, V).\end{aligned}$$

Thus,

$$\operatorname{Hom}_{\mathbb{C}H}(\operatorname{Res}_\rho U, V) \cong \operatorname{Hom}_{\mathbb{C}G}\left(U, \underbrace{\operatorname{Hom}_{\mathbb{C}H}(\mathbb{C}G, V)}_{\substack{\cong \operatorname{Ind}_\rho V \text{ as left } \mathbb{C}G\text{-modules} \\ \text{(by (13.111.73))}}}\right) \cong \operatorname{Hom}_{\mathbb{C}G}(U, \operatorname{Ind}_\rho V).$$

This solves Exercise 4.1.14(j).

(k) *Alternative proof of (4.1.3):* Let G be a finite group, and let H be a subgroup of G. Let U be a finite-dimensional $\mathbb{C}H$-module. We need to prove the identity (4.1.3).

Let ρ denote the inclusion map $H \to G$. Clearly, ρ is a group homomorphism. But Exercise 4.1.14(d) yields $\operatorname{Ind}_\rho U = \operatorname{Ind}_H^G U$. Hence, $\chi_{\operatorname{Ind}_\rho U} = \chi_{\operatorname{Ind}_H^G U}$, so that $\chi_{\operatorname{Ind}_H^G U} = \chi_{\operatorname{Ind}_\rho U} = \operatorname{Ind}_\rho \chi_U$ (by Exercise 4.1.14(b)). But Exercise 4.1.14(c) (applied to $f = \chi_U$) yields $\operatorname{Ind}_\rho \chi_U = \operatorname{Ind}_H^G \chi_U$. Thus, $\chi_{\operatorname{Ind}_H^G U} = \operatorname{Ind}_\rho \chi_U = \operatorname{Ind}_H^G \chi_U$. Thus, every $g \in G$ satisfies

$$\underbrace{\chi_{\operatorname{Ind}_H^G U}}_{= \operatorname{Ind}_H^G \chi_U}(g) = \left(\operatorname{Ind}_H^G \chi_U\right)(g) = \frac{1}{|H|} \sum_{\substack{k \in G: \\ kgk^{-1} \in H}} \chi_U\left(kgk^{-1}\right) \qquad \left(\text{by the definition of } \operatorname{Ind}_H^G \chi_U\right).$$

This proves (4.1.3). Thus, Exercise 4.1.14(k) is solved.

(l) *Alternative proof of (4.1.12):* Let G be a finite group, and let K be a normal subgroup of G. Let V be a finite-dimensional $\mathbb{C}G$-module. We need to prove the identity (4.1.12).

Let ρ denote the projection map $G \to G/K$. Exercise 4.1.14(f) (applied to G/K, G and V instead of G, H and U) yields $\operatorname{Ind}_\rho V \cong V^K$ as $\mathbb{C}[G/K]$-modules. Hence, $\chi_{\operatorname{Ind}_\rho V} = \chi_{V^K}$ (since isomorphic $\mathbb{C}[G/K]$-modules have equal characters). Thus, $\chi_{V^K} = \chi_{\operatorname{Ind}_\rho V} = \operatorname{Ind}_\rho \chi_V$ (by Exercise 4.1.14(b), applied to G/K, G and V instead of G, H and U). But Exercise 4.1.14(e) (applied to G/K, G, V and χ_V instead of G, H, U and f) yields $\operatorname{Ind}_\rho \chi_V = (\chi_V)^K$. Hence, $\chi_{V^K} = \operatorname{Ind}_\rho \chi_V = (\chi_V)^K$. Thus, every $g \in G$ satisfies

$$\underbrace{\chi_{V^K}}_{=(\chi_V)^K}(gK) = (\chi_V)^K(gK) = \frac{1}{|K|} \sum_{k \in K} \chi_V(gk)$$

(by the definition of $(\chi_V)^K$). This proves (4.1.12). Thus, Exercise 4.1.14(l) is solved.

[*Remark:* Most parts of Exercise 4.1.14 work in a far greater generality than they are stated in. Let us briefly survey the straightforward generalizations. We begin with the generalizations of the notions of induction, restriction, inflation and fixed point constructions defined in Chapter 4.1:

- Recall that if G is a finite group and H is a subgroup of G, then we have defined a $\mathbb{C}G$-module $\operatorname{Ind}_H^G U$ for every $\mathbb{C}H$-module U, and we have also defined a $\mathbb{C}H$-module $\operatorname{Res}_H^G V$ for every $\mathbb{C}G$-module V. Both of these definitions are also valid when $\mathbb{C}$ is replaced by any commutative ring. Basic properties of induction and restriction (such as the equality (4.1.7), the statement of Exercise 4.1.2 and the statement of Exercise 4.1.3) are still true in this generality (and the proofs that we gave can be transferred to this generality with almost no changes). However, more advanced properties might fail in this generality, and some can not even be stated over a general commutative ring $\mathbb{C}$ [843].

[843] For instance, any properties of characters of modules can only be stated when these characters are well-defined. Since characters are defined as traces of certain endomorphisms of $\mathbb{C}$-vector spaces, they are not automatically well-defined when $\mathbb{C}$

- Recall that if G is a finite group and K is a normal subgroup of G, then we have defined a $\mathbb{C}G$-module $\operatorname{Infl}_{G/K}^{G} U$ for every $\mathbb{C}\left[G/K\right]$-module U, and we have also defined a $\mathbb{C}\left[G/K\right]$-module V^{K} for every $\mathbb{C}G$-module V. Both of these definitions are also valid when $\mathbb{C}$ is replaced by any commutative ring. Some basic properties of inflation and fixed points (such as the isomorphisms (4.1.10) and (4.1.11)) are still correct in this generality (again, they can be proven in the same way as above), but some others are not (e.g., Exercise 4.1.12(b) is generally false[844]).
- If G is a finite group, then we defined $R_{\mathbb{C}}\left(G\right)$ as the $\mathbb{C}$-vector space of all class functions $G \to \mathbb{C}$. This definition still applies when $\mathbb{C}$ is replaced by any commutative ring. (Of course, in this case, "$\mathbb{C}$-vector space" will have to be replaced by "$\mathbb{C}$-module".)
- Recall that if G is a finite group and H is a subgroup of G, then we have defined a class function $\operatorname{Ind}_{H}^{G} f \in R_{\mathbb{C}}\left(G\right)$ for every $f \in R_{\mathbb{C}}\left(H\right)$, and we have also defined a class function $\operatorname{Res}_{H}^{G} f \in R_{\mathbb{C}}\left(H\right)$ for every $f \in R_{\mathbb{C}}\left(G\right)$. The definition of $\operatorname{Res}_{H}^{G} f$ still works when $\mathbb{C}$ is replaced by any commutative ring. Our definition of $\operatorname{Ind}_{H}^{G} f$ cannot be reasonably interpreted in this generality (due to the denominator $\left|H\right|$ in (4.1.4)); however, Exercise 4.1.1(b) can be used as an alternative definition of $\operatorname{Ind}_{H}^{G} f$ when $\mathbb{C}$ is replaced by any commutative ring. (Of course, the necessity of using Exercise 4.1.1(b) as a definition of $\operatorname{Ind}_{H}^{G} f$ entails that most of our proofs concerning $\operatorname{Ind}_{H}^{G} f$ no longer are valid in this generality, because they use the equality (4.1.4) as the definition of $\operatorname{Ind}_{H}^{G} f$. Even the fact that $\operatorname{Ind}_{H}^{G} f$ is well-defined needs to be proven anew, since it is not immediately obvious that the sum $\sum\limits_{\substack{j \in J;\\ jgj^{-1} \in H}} f\left(jgj^{-1}\right)$ in Exercise 4.1.1(b) is independent on J.)

Now, let us move on to generalizing Remark 4.1.13 and Exercise 4.1.14. Let G and H be two finite groups, and let $\rho : H \to G$ be a group homomorphism.

- Remark 4.1.13 still holds if $\mathbb{C}$ is replaced by any commutative ring.
- In Exercise 4.1.14, we defined a map $\operatorname{Ind}_{\rho} f : G \to \mathbb{C}$ for every $f \in R_{\mathbb{C}}\left(H\right)$. This definition still works when $\mathbb{C}$ is replaced by any commutative ring in which $\left|H\right|$ is invertible. There is an alternative definition which works in even greater generality: Namely, as long as $\left|\ker\rho\right|$ is invertible[845], we can define $\operatorname{Ind}_{\rho} f : G \to \mathbb{C}$ by the equality

$$\left(\operatorname{Ind}_{\rho} f\right)\left(g\right) = \frac{1}{\left|\ker\rho\right|} \sum_{\substack{(h,k) \in H \times J;\\ k\rho(h)k^{-1}=g}} f\left(h\right), \tag{13.111.77}$$

where J is a system of left coset representatives for $G/\rho\left(H\right)$ (so that $G = \bigsqcup_{j \in J} j\rho\left(H\right)$). We leave it to the reader to show that this definition is still well-defined (i.e., that $\sum\limits_{\substack{(h,k) \in H \times J;\\ k\rho(h)k^{-1}=g}} f\left(h\right)$ is independent of the choice of J), and that it defines the same function $\operatorname{Ind}_{\rho} f$ as the definition made in Exercise 4.1.14 when $\left|H\right|$ is invertible in the base ring. To my knowledge, there exists no reasonable definition of $\operatorname{Ind}_{\rho} f$ that completely avoids making any requirements on the base ring.
- In Exercise 4.1.14, we defined a $\mathbb{C}G$-module $\operatorname{Ind}_{\rho} U$ for every $\mathbb{C}H$-module U. This definition is still valid when $\mathbb{C}$ is replaced by a commutative ring. (Notice the slightly surprising fact that if $\mathbb{C}$ is replaced by a commutative ring, then the ρ-induction of a $\mathbb{C}H$-module is always well-defined, whereas the ρ-induction of a class function might not be.)
- Exercise 4.1.14(a) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $\left|H\right|$ is invertible. And the solution that we gave still applies in this generality. More generally, if we define $\operatorname{Ind}_{\rho} f$ by (13.111.77), then Exercise 4.1.14(a) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $\left|\ker\rho\right|$ is invertible. However, this can no longer be proven by blindly copying our solution.

is replaced by a commutative ring. They are, however, well-defined if our modules are projective modules over this base ring; see the Remark after the proof of Proposition 13.111.3 for details.

[844] However, Exercise 4.1.12(b) holds if we additionally assume that $\left|K\right|$ is invertible in the ring that replaces $\mathbb{C}$. Again, this can be proven by repeating our solution of Exercise 4.1.12(b).

[845] This is a weaker condition than $\left|H\right|$ being invertible.

- Exercise 4.1.14(b) is still valid when $\mathbb{C}$ is replaced by any field in which $|H|$ is invertible. Again, our solution is still valid in this generality.[846] More generally, Exercise 4.1.14(b) is still valid when $\mathbb{C}$ is replaced by any field in which $|\ker\rho|$ is invertible (as long as $\operatorname{Ind}_\rho f$ is defined through (13.111.77)); but our solution is not sufficient to prove this[847]. Even more generally, Exercise 4.1.14(b) holds whenever $\mathbb{C}$ is replaced by any **commutative ring** A in which $|\ker\rho|$ is invertible, as long as U is assumed to be a finitely generated projective A-module. However, in order to make sense of this statement, one needs to know that $\operatorname{Ind}_\rho U$ is a finitely generated projective A-module as well, and one needs to know how the trace of an endomorphism of a finitely generated projective A-module is defined. We essentially did most of this in our solution above[848].
- Exercise 4.1.14(c) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $|H|$ is invertible. Again, our solution is still valid in this generality. Again, if we define $\operatorname{Ind}_\rho f$ by (13.111.77) and define $\operatorname{Ind}_H^G f$ by Exercise 4.1.1(b), then Exercise 4.1.14(c) even holds when $\mathbb{C}$ is replaced by any arbitrary commutative ring. (The definition of $\operatorname{Ind}_\rho f$ requires $|\ker\rho|$ to be invertible, but this is automatically satisfied since ρ is injective.)
- Exercise 4.1.14(d) is still valid when $\mathbb{C}$ is replaced by any commutative ring whatsoever. Again, our solution is still valid in this generality.
- Exercise 4.1.14(e) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $|H|$ is invertible. Again, our solution is still valid in this generality. Again, it is possible to prove Exercise 4.1.14(e) also when $\mathbb{C}$ is replaced by any commutative ring in which $|\ker\rho|$ is invertible (as long as $\operatorname{Ind}_\rho f$ is defined using (13.111.77)). (This is actually very easy to check – arguably even easier than our above solution of Exercise 4.1.14(e).)
- Exercise 4.1.14(f) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $|K|$ is invertible. Both solutions of Exercise 4.1.14(f) given above still remain valid in this generality.
- The second claim of Exercise 4.1.14(g) (that is, the equality (4.1.17)) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $|G|$ and $|H|$ are invertible. The first claim, a priori, makes no sense when $\mathbb{C}$ is replaced by an arbitrary commutative ring, because the definition of the Hermitian forms $(\cdot,\cdot)_G$ and $(\cdot,\cdot)_H$ involves complex conjugation (which is only defined on $\mathbb{C}$). However, it turns out that this complex conjugation can be replaced by **any map from the base ring to itself** and Exercise 4.1.14(g) remains valid[849].

[846] We can also replace $\mathbb{C}$ by a commutative ring A rather than by a field; but then we need to replace "finite-dimensional $\mathbb{C}H$-module U" by "AH-module U which is a finitely generated projective A-module" in the statement of the exercise. The "finitely generated projective A-module" condition is needed in order to make sure that χ_U and $\chi_{\operatorname{Ind}_\rho U}$ are well-defined. (See the Remark after the proof of Proposition 13.111.3 for details.)

[847] However, a certain modification of this solution does the trick. Namely, we replace the definition of $\widetilde{F}_g$ by

$$\left(\widetilde{F}_g(\gamma,u)=\frac{1}{|\ker\rho|}\sum_{h\in H}(g\rho(h))^*(\gamma)\,hu\qquad\text{for all }(\gamma,u)\in\mathbb{C}G\times U\right).$$

Then, we should pick a system J' of left coset representatives for $G/\rho(H)$ (so that $G=\bigsqcup_{j\in J'}j\rho(H)$). (Notice that we do not call it J because the letter J already has a different meaning in this solution.) Then, we define a family $(a_i)_{i\in J'\times J}$ of elements of $\mathbb{C}G\otimes_{\mathbb{C}H}U$ by

$$\left(a_{(k,j)}=k\otimes_{\mathbb{C}H}b_j\qquad\text{for all }(k,j)\in J'\times J\right),$$

and a family $(f_i)_{i\in J'\times J}$ of elements of $(\mathbb{C}G\otimes_{\mathbb{C}H}U)^*$ by

$$\left(f_{(k,j)}=g_j\circ F_k\qquad\text{for all }(k,j)\in J'\times J\right).$$

(Notice that these families $(a_i)_{i\in J'\times J}$ and $(f_i)_{i\in J'\times J}$ are subfamilies of the families $(a_i)_{i\in G\times J}$ and $(f_i)_{i\in G\times J}$ from the original solution to Exercise 4.1.14(b).) It can then be shown that $\left(J'\times J,(a_i)_{i\in J'\times J},(f_i)_{i\in J'\times J}\right)$ is a finite dual generating system for $\operatorname{Ind}_\rho U$ (though the proof is somewhat different from the way this was shown in the solution to Exercise 4.1.14(b)). This allows us to use Proposition 13.111.3 to derive $\chi_{\operatorname{Ind}_\rho U}=\operatorname{Ind}_\rho\chi_U$. All details are left to the reader.

[848] The only missing link is the fact that an A-module is finitely generated and projective if and only if it has a finite dual generating system; this fact is easy to prove.

[849] More precisely: Let A be any commutative ring in which $|G|$ and $|H|$ are invertible. Fix an arbitrary map $\operatorname{conj}:A\to A$ (not necessarily linear). For every $a\in A$, let $\overline{a}$ denote the image $\operatorname{conj}(a)$ of a under this map. For any $f_1\in R_A(G)$ and $f_2\in R_A(G)$, define $(f_1,f_2)_G\in A$ by $(f_1,f_2)_G=\dfrac{1}{|G|}\sum_{g\in G}f_1(g)\overline{f_2(g)}$ (using the notation $\overline{a}$ that we just introduced). Similarly, define $(f_1,f_2)_H\in A$ for any $f_1\in R_A(H)$ and $f_2\in R_A(H)$. Then, Exercise 4.1.14(g) is still valid when $\mathbb{C}$ is replaced by A. (And our solution to this exercise still applies.)

- Exercise 4.1.14(h) is still valid when $\mathbb{C}$ is replaced by any commutative ring whatsoever. Again, our solution is still valid in this generality.
- Exercise 4.1.14(i) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $|\ker \rho|$ is invertible. Again, our solution is still valid in this generality (because if we set $K = \ker \rho$ as we did in our solution, then $\left| \underbrace{K}_{= \ker \rho} \right| = |\ker \rho|$ is invertible).
- Exercise 4.1.14(j) is still valid when $\mathbb{C}$ is replaced by any commutative ring in which $|\ker \rho|$ is invertible.
- Exercise 4.1.14(k) still gives a proof of the formula (4.1.3) when $\mathbb{C}$ is replaced by any field in which $|H|$ is invertible.
- Exercise 4.1.14(l) still gives a proof of the formula (4.1.12) when $\mathbb{C}$ is replaced by any field in which $|G|$ and $|K|$ are invertible.

We actually tailored our above solutions to apply in a reasonably high generality (although we did not state Exercise 4.1.14 in this generality). Had we contented ourselves with solving no more and no less than what Exercise 4.1.14 demanded of us, we could have obtained much shorter solutions of some parts of it:

- Exercise 4.1.14(b) can be obtained by combining parts (g) and (h) of Exercise 4.1.14 with the following two observations[850]:
  - Every $\mathbb{C}G$-module V satisfies $\chi_{\operatorname{Res}_\rho V} = \operatorname{Res}_\rho \chi_V$. (This is obvious.)
  - If α and β are two elements of $R_{\mathbb{C}}(G)$ such that every finite-dimensional $\mathbb{C}G$-module V satisfies $(\alpha, \chi_V)_G = (\beta, \chi_V)_G$, then $\alpha = \beta$. (This follows from the fact that $R(G)$ spans the $\mathbb{C}$-vector space $R_{\mathbb{C}}(G)$ and from the fact that the Hermitian form $(\cdot, \cdot)_G$ is nondegenerate.)

  However, this quick argument only works when the base ring is $\mathbb{C}$. It cannot be easily generalized to the case when $\mathbb{C}$ is replaced by any field in which $|H|$ is invertible.
- Part (e) (at least in the case when U is finite-dimensional) and part (f) of Exercise 4.1.14 can be derived from each other using the correspondence between irreducible representations and irreducible characters. Again, this argument is quick but hard to generalize.

]

13.112. **Solution to Exercise 4.1.15.** *Solution to Exercise 4.1.15.* We shall use the following fact:

Proposition 13.112.1. *Let* $\mathbf{k}$ *be a commutative ring. Let* A, B, C, A', B' *and* C' *be six* $\mathbf{k}$*-algebras. Let* P *be an* (A, B)*-bimodule*[851]. *Let* Q *be a* (B, C)*-bimodule. Let* P' *be an* (A', B')*-bimodule. Let* Q' *be a* (B', C')*-bimodule. Then,*

$$(P \otimes P') \otimes_{B \otimes B'} (Q \otimes Q') \cong (P \otimes_B Q) \otimes (P' \otimes_{B'} Q')$$

as $(A \otimes A', C \otimes C')$*-bimodules. Here, all* $\otimes$ *signs without subscript stand for* $\otimes_{\mathbf{k}}$.

Proposition 13.112.1 is identical with the Proposition 13.104.1 that appeared in our solution to Exercise 4.1.3. It is proven by straightforward (repeated) use of the universal property of the tensor product.

We have a canonical $\mathbb{C}$-algebra isomorphism

$$\mathfrak{H} : \mathbb{C}[H_1 \times H_2] \to \mathbb{C}H_1 \otimes \mathbb{C}H_2$$

which satisfies

$$\mathfrak{H}\left(t_{(h_1,h_2)}\right) = t_{h_1} \otimes t_{h_2} \qquad \text{for every } (h_1, h_2) \in H_1 \times H_2.$$

We also have a canonical $\mathbb{C}$-algebra isomorphism

$$\mathfrak{G} : \mathbb{C}[G_1 \times G_2] \to \mathbb{C}G_1 \otimes \mathbb{C}G_2$$

which satisfies

$$\mathfrak{G}\left(t_{(g_1,g_2)}\right) = t_{g_1} \otimes t_{g_2} \qquad \text{for every } (g_1, g_2) \in G_1 \times G_2.$$

[850] We only sketch this argument; the details are left to the reader.

[851] As usual, we understand the notion of a bimodule to be defined over $\mathbf{k}$; that is, the left A-module structure and the right B-module structure of an (A, B)-bimodule must restrict to one and the same $\mathbf{k}$-module structure.

Recall how the left $\mathbb{C}[H_1 \times H_2]$-module $U_1 \otimes U_2$ is defined: Its left $\mathbb{C}[H_1 \times H_2]$-module structure is given by

$$\left(t_{(h_1,h_2)}(u_1 \otimes u_2) = t_{h_1}u_1 \otimes t_{h_2}u_2 \qquad \text{for all } (h_1,h_2) \in H_1 \times H_2 \text{ and } (u_1,u_2) \in U_1 \times U_2\right).$$

We shall now recall the definitions of $\operatorname{Ind}_{\rho_1} U_1$, $\operatorname{Ind}_{\rho_2} U_2$ and $\operatorname{Ind}_{\rho_1 \times \rho_2}(U_1 \otimes U_2)$:

- We defined $\operatorname{Ind}_{\rho_1}(U_1)$ as the $\mathbb{C}G_1$-module $\mathbb{C}G_1 \otimes_{\mathbb{C}H_1} U_1$, where $\mathbb{C}G_1$ is regarded as a $(\mathbb{C}G_1, \mathbb{C}H_1)$-bimodule according to the following rule: The left $\mathbb{C}G_1$-module structure on $\mathbb{C}G_1$ is plain multiplication inside $\mathbb{C}G_1$; the right $\mathbb{C}H_1$-module structure on $\mathbb{C}G_1$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho_1] : \mathbb{C}H_1 \to \mathbb{C}G_1$ (thus, it is explicitly given by $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho_1])\eta$ for all $\gamma \in \mathbb{C}G_1$ and $\eta \in \mathbb{C}H_1$).
- We defined $\operatorname{Ind}_{\rho_2}(U_2)$ as the $\mathbb{C}G_2$-module $\mathbb{C}G_2 \otimes_{\mathbb{C}H_2} U_2$, where $\mathbb{C}G_2$ is regarded as a $(\mathbb{C}G_2, \mathbb{C}H_2)$-bimodule in a similar fashion.
- We defined $\operatorname{Ind}_{\rho_1 \times \rho_2}(U_1 \otimes U_2)$ as the $\mathbb{C}[G_1 \times G_2]$-module $\mathbb{C}[G_1 \times G_2] \otimes_{\mathbb{C}[H_1 \times H_2]} (U_1 \otimes U_2)$, where $\mathbb{C}[G_1 \times G_2]$ is regarded as a $(\mathbb{C}[G_1 \times G_2], \mathbb{C}[H_1 \times H_2])$-bimodule in a similar fashion.

Proposition 13.104.1 (applied to $\mathbf{k} = \mathbb{C}$, $A = \mathbb{C}G_1$, $B = \mathbb{C}H_1$, $C = \mathbb{C}$, $A' = \mathbb{C}G_2$, $B' = \mathbb{C}H_2$, $C' = \mathbb{C}$, $P = \mathbb{C}G_1$, $Q = U_1$, $P' = \mathbb{C}G_2$ and $Q' = U_2$) yields

$$(\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \cong (\mathbb{C}G_1 \otimes_{\mathbb{C}H_1} U_1) \otimes (\mathbb{C}G_2 \otimes_{\mathbb{C}H_2} U_2)$$

as $(\mathbb{C}G_1 \otimes \mathbb{C}G_2, \mathbb{C} \otimes \mathbb{C})$-bimodules, hence also as left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-modules. Thus,

$$\begin{aligned}
&(\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \\
&\cong \underbrace{(\mathbb{C}G_1 \otimes_{\mathbb{C}H_1} U_1)}_{=\operatorname{Ind}_{\rho_1} U_1} \otimes \underbrace{(\mathbb{C}G_2 \otimes_{\mathbb{C}H_2} U_2)}_{=\operatorname{Ind}_{\rho_2} U_2} \\
&= (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)
\end{aligned} \tag{13.112.1}$$

as left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-modules.

At this point, there is a quick way to finish the solution using handwaving: We use the $\mathbb{C}$-algebra isomorphism $\mathfrak{H} : \mathbb{C}[H_1 \times H_2] \to \mathbb{C}H_1 \otimes \mathbb{C}H_2$ to identify the $\mathbb{C}$-algebra $\mathbb{C}[H_1 \times H_2]$ with the $\mathbb{C}$-algebra $\mathbb{C}H_1 \otimes \mathbb{C}H_2$, and we use the $\mathbb{C}$-algebra isomorphism $\mathfrak{G} : \mathbb{C}[G_1 \times G_2] \to \mathbb{C}G_1 \otimes \mathbb{C}G_2$ to identify the $\mathbb{C}$-algebra $\mathbb{C}[G_1 \times G_2]$ with the $\mathbb{C}$-algebra $\mathbb{C}G_1 \otimes \mathbb{C}G_2$. It is "easy to see" that these two identifications "play nicely with each other and with the module structures on $U_1 \otimes U_2$" (this is the part where we wave our hands). Now, (13.112.1) yields that $(\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \cong (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)$ as left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-modules, and therefore also as left $\mathbb{C}[G_1 \times G_2]$-modules (since $\mathbb{C}[G_1 \times G_2] = \mathbb{C}G_1 \otimes \mathbb{C}G_2$). Now,

$$\begin{aligned}
\operatorname{Ind}_{\rho_1 \times \rho_2}(U_1 \otimes U_2) &= \mathbb{C}[G_1 \times G_2] \otimes_{\mathbb{C}[H_1 \times H_2]} (U_1 \otimes U_2) \\
&= (\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \\
&\qquad (\text{since } \mathbb{C}[G_1 \times G_2] = \mathbb{C}G_1 \otimes \mathbb{C}G_2 \text{ and } \mathbb{C}[H_1 \times H_2] = \mathbb{C}H_1 \otimes \mathbb{C}H_2) \\
&\cong (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)
\end{aligned}$$

as left $\mathbb{C}[G_1 \times G_2]$-modules. This solves Exercise 4.1.15 if you believe the handwaving I have done above.

The handwaving we have done is slightly questionable, since we have made two identifications which turned two isomorphisms into identities. In reality, they are merely isomorphisms, not identities, and it is not immediately clear that regarding them as identities will not lead to contradictions. (Indeed, this is the meaning of our vague claim that the two identifications "play nicely with each other".)

Let us now show a way to formalize the above questionable argument. We shall focus on explaining how to do this proof in a clean fashion (in particular, we shall avoid identifying any things that are not already identical; instead, we will work with the isomorphisms $\mathfrak{G}$ and $\mathfrak{H}$ explicitly); we will leave straightforward computations and arguments to the reader.

We first state a general fact:

Proposition 13.112.2. *Let $\mathbf{k}$ be a commutative ring. In the following, all $\otimes$ signs without subscript stand for $\otimes_{\mathbf{k}}$.*

Let A, B, C, A', B' and C' be six $\mathbf{k}$-algebras. Let M be an (A,B)-bimodule[852]*. Let N be a (B,C)-bimodule. Let M' be an (A',B')-bimodule. Let N' be a (B',C')-bimodule. Let $\beta : B \to B'$, $\mu : M \to M'$*

[852] As usual, we understand the notion of a bimodule to be defined over $\mathbf{k}$; that is, the left A-module structure and the right B-module structure of an (A,B)-bimodule must restrict to one and the same $\mathbf{k}$-module structure.

and $\nu : N \to N'$ be three **k***-module homomorphisms. Assume that we have*

$$(\mu(mb) = \mu(m)\beta(b) \qquad \text{for all } b \in B \text{ and } m \in M) \tag{13.112.2}$$

and

$$(\nu(bn) = \beta(b)\nu(n) \qquad \text{for all } b \in B \text{ and } n \in N). \tag{13.112.3}$$

Then:

(a) *There exists a unique* **k***-module homomorphism*

$$\Omega : M \otimes_B N \to M' \otimes_{B'} N'$$

which satisfies

$$(\Omega(m \otimes_B n) = \mu(m) \otimes_{B'} \nu(n) \qquad \text{for all } (m,n) \in M \times N).$$

We shall denote this homomorphism Ω by $\Omega_{\beta,\mu,\nu}$.

(b) *If the maps β, μ and ν are invertible, then $\Omega_{\beta,\mu,\nu}$ is a* **k***-module isomorphism.*

(c) *Let $\alpha : A \to A'$ be a* **k***-module homomorphism. Assume that*

$$\mu(am) = \alpha(a)\mu(m) \qquad \text{for all } a \in A \text{ and } m \in M. \tag{13.112.4}$$

Assume also that the **k***-module M' is endowed with a left A-module structure. Assume that this left A-module structure on M' and the right B'-module structure on M' together form an (A,B')-bimodule structure on M'. Thus, $M' \otimes_{B'} N'$ becomes a left A-module. Assume furthermore that*

$$am = \alpha(a)m \qquad \text{for every } a \in A \text{ and } m \in M' \tag{13.112.5}$$

[853]*. Then, $\Omega_{\beta,\mu,\nu}$ is a left A-module homomorphism.*

The proof of Proposition 13.112.2 is straightforward[854] and is left to the reader. We could also add a part (d) to Proposition 13.112.2, which would give a criterion for $\Omega_{\beta,\mu,\nu}$ to be a right C-module homomorphism given an appropriate right C-module structure on N'.

Let us now return to solving Exercise 4.1.15. We have four bimodules:

- The $\mathbb{C}$-vector space $\mathbb{C}G_1 \otimes \mathbb{C}G_2$ is a $(\mathbb{C}G_1 \otimes \mathbb{C}G_2, \mathbb{C}H_1 \otimes \mathbb{C}H_2)$-bimodule (because it is the tensor product of the $(\mathbb{C}G_1, \mathbb{C}H_1)$-bimodule $\mathbb{C}G_1$ with the $(\mathbb{C}G_2, \mathbb{C}H_2)$-bimodule $\mathbb{C}G_2$). As a left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-module, it is thus the tensor product of the left $\mathbb{C}G_1$-module $\mathbb{C}G_1$ with the left $\mathbb{C}G_2$-module $\mathbb{C}G_2$. Hence, its left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-module structure is given by plain multiplication inside $\mathbb{C}G_1 \otimes \mathbb{C}G_2$ [855]. (This is straightforward to check.)
- The $\mathbb{C}$-vector space $U_1 \otimes U_2$ is a left $\mathbb{C}H_1 \otimes \mathbb{C}H_2$-module (because it is the tensor product of the left $\mathbb{C}H_1$-module U_1 with the left $\mathbb{C}H_2$-module U_2), and thus a $(\mathbb{C}H_1 \otimes \mathbb{C}H_2, \mathbb{C})$-bimodule.
- The $\mathbb{C}$-vector space $\mathbb{C}[G_1 \times G_2]$ is a $(\mathbb{C}[G_1 \times G_2], \mathbb{C}[H_1 \times H_2])$-bimodule (as we already know).
- The $\mathbb{C}$-vector space $U_1 \otimes U_2$ is a left $\mathbb{C}[H_1 \times H_2]$-module (since it is the tensor product of the left $\mathbb{C}H_1$-module U_1 with the left $\mathbb{C}H_2$-module U_2), and thus a $(\mathbb{C}[H_1 \times H_2], \mathbb{C})$-bimodule.

We have

$$(\mathfrak{G}(mb) = \mathfrak{G}(m)\mathfrak{H}(b) \qquad \text{for all } b \in \mathbb{C}[H_1 \times H_2] \text{ and } m \in \mathbb{C}[G_1 \times G_2]) \tag{13.112.6}$$

and

$$(\operatorname{id}(bn) = \mathfrak{H}(b)\operatorname{id}(n) \qquad \text{for all } b \in \mathbb{C}[H_1 \times H_2] \text{ and } n \in U_1 \otimes U_2). \tag{13.112.7}$$

(In fact, both of these equalities are easily checked on basis elements and pure tensors.) Hence, we can apply Proposition 13.112.2(a) to $\mathbf{k} = \mathbb{C}$, $A = \mathbb{C}[G_1 \times G_2]$, $B = \mathbb{C}[H_1 \times H_2]$, $C = \mathbb{C}$, $A' = \mathbb{C}G_1 \otimes \mathbb{C}G_2$, $B' = \mathbb{C}H_1 \otimes \mathbb{C}H_2$, $C' = \mathbb{C}$, $M = \mathbb{C}[G_1 \times G_2]$, $N = U_1 \otimes U_2$, $M' = \mathbb{C}G_1 \otimes \mathbb{C}G_2$, $N' = U_1 \otimes U_2$, $\beta = \mathfrak{H}$, $\mu = \mathfrak{G}$ and $\nu = \operatorname{id}$. As a consequence, we conclude that there exists a unique $\mathbb{C}$-module homomorphism

$$\Omega : \mathbb{C}[G_1 \times G_2] \otimes_{\mathbb{C}[H_1 \times H_2]} (U_1 \otimes U_2) \to (\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2)$$

[853] Here the $\alpha(a)m$ on the right hand side is defined using the action of A' on the left A'-module M', whereas the am on the left hand side is defined using the action of A on the left A-module M'.

[854] For part (b), the inverse of $\Omega_{\beta,\mu,\nu}$ is $\Omega_{\beta^{-1},\mu^{-1},\nu^{-1}}$, of course.

[855] That is, the action of any $a \in \mathbb{C}G_1 \otimes \mathbb{C}G_2$ on any element m of the left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-module $\mathbb{C}G_1 \otimes \mathbb{C}G_2$ equals the product of a with m in the $\mathbb{C}$-algebra $\mathbb{C}G_1 \otimes \mathbb{C}G_2$.

which satisfies

$$\left(\Omega\left(m \otimes_{\mathbb{C}[H_1\times H_2]} n\right) = \mathfrak{G}(m) \otimes_{\mathbb{C}H_1\otimes\mathbb{C}H_2} \mathrm{id}(n) \qquad \text{for all } (m,n) \in \mathbb{C}[G_1\times G_2] \times (U_1\otimes U_2)\right).$$

According to Proposition 13.112.2(a), this homomorphism Ω is denoted by $\Omega_{\mathfrak{H},\mathfrak{G},\mathrm{id}}$.

The maps $\mathfrak{H}$, $\mathfrak{G}$ and id are $\mathbb{C}$-algebra isomorphisms, and therefore invertible. Hence, Proposition 13.112.2(b) (applied to $\mathbf{k} = \mathbb{C}$, $A = \mathbb{C}[G_1\times G_2]$, $B = \mathbb{C}[H_1\times H_2]$, $C = \mathbb{C}$, $A' = \mathbb{C}G_1\otimes\mathbb{C}G_2$, $B' = \mathbb{C}H_1\otimes\mathbb{C}H_2$, $C' = \mathbb{C}$, $M = \mathbb{C}[G_1\times G_2]$, $N = U_1\otimes U_2$, $M' = \mathbb{C}G_1\otimes\mathbb{C}G_2$, $N' = U_1\otimes U_2$, $\beta = \mathfrak{H}$, $\mu = \mathfrak{G}$ and $\nu = \mathrm{id}$) yields that $\Omega_{\mathfrak{H},\mathfrak{G},\mathrm{id}}$ is a $\mathbb{C}$-module isomorphism.

Next, we notice that the $\mathbb{C}$-vector space $\mathbb{C}G_1\otimes\mathbb{C}G_2$ is a left $\mathbb{C}[G_1\times G_2]$-module (since it is the tensor product of the left $\mathbb{C}G_1$-module $\mathbb{C}G_1$ with the left $\mathbb{C}G_2$-module $\mathbb{C}G_2$). This left $\mathbb{C}[G_1\times G_2]$-module structure is defined by the rule

$$(13.112.8)\quad t_{(g_1,g_2)}(u_1\otimes u_2) = t_{g_1}u_1\otimes t_{g_2}u_2 \qquad \text{for all } (g_1,g_2)\in G_1\times G_2 \text{ and } (u_1,u_2)\in\mathbb{C}G_1\times\mathbb{C}G_2.$$

This left $\mathbb{C}[G_1\times G_2]$-module structure on $\mathbb{C}G_1\otimes\mathbb{C}G_2$ and the right $\mathbb{C}H_1\otimes\mathbb{C}H_2$-module structure on $\mathbb{C}G_1\otimes\mathbb{C}G_2$ are connected by the equality

$$(13.112.9)\qquad ((gm)h = g(mh) \qquad \text{for all } g\in\mathbb{C}[G_1\times G_2],\ m\in\mathbb{C}G_1\otimes\mathbb{C}G_2 \text{ and } h\in\mathbb{C}H_1\otimes\mathbb{C}H_2)$$

(which is easily checked). Hence, these two structures together form an $(\mathbb{C}[G_1\times G_2], \mathbb{C}H_1\otimes\mathbb{C}H_2)$-bimodule structure on $\mathbb{C}G_1\otimes\mathbb{C}G_2$ (because both of these structures are $\mathbb{C}$-bilinear). Thus, the tensor product $(\mathbb{C}G_1\otimes\mathbb{C}G_2)\otimes_{\mathbb{C}H_1\otimes\mathbb{C}H_2}(U_1\otimes U_2)$ becomes a left $\mathbb{C}[G_1\times G_2]$-module.

Next, it is easy to check that

$$(13.112.10)\qquad \mathfrak{G}(am) = \mathfrak{G}(a)\,\mathfrak{G}(m) \qquad \text{for all } a\in\mathbb{C}[G_1\times G_2] \text{ and } m\in\mathbb{C}[G_1\times G_2].$$

It is also easy to see that

$$(13.112.11)\qquad am = \mathfrak{G}(a)\,m \qquad \text{for every } a\in\mathbb{C}[G_1\times G_2] \text{ and } m\in\mathbb{C}G_1\otimes\mathbb{C}G_2.$$

Thus, we can apply Proposition 13.112.2(c) to $\mathbf{k} = \mathbb{C}$, $A = \mathbb{C}[G_1\times G_2]$, $B = \mathbb{C}[H_1\times H_2]$, $C = \mathbb{C}$, $A' = \mathbb{C}G_1\otimes\mathbb{C}G_2$, $B' = \mathbb{C}H_1\otimes\mathbb{C}H_2$, $C' = \mathbb{C}$, $M = \mathbb{C}[G_1\times G_2]$, $N = U_1\otimes U_2$, $M' = \mathbb{C}G_1\otimes\mathbb{C}G_2$, $N' = U_1\otimes U_2$, $\beta = \mathfrak{H}$, $\mu = \mathfrak{G}$, $\nu = \mathrm{id}$ and $\alpha = \mathfrak{G}$. As a result, we obtain that $\Omega_{\mathfrak{H},\mathfrak{G},\mathrm{id}}$ is a left $\mathbb{C}[G_1\times G_2]$-module homomorphism. Hence, $\Omega_{\mathfrak{H},\mathfrak{G},\mathrm{id}}$ is a left $\mathbb{C}[G_1\times G_2]$-module isomorphism (since $\Omega_{\mathfrak{H},\mathfrak{G},\mathrm{id}}$ is invertible). Thus,

$$(13.112.12)\qquad \mathbb{C}[G_1\times G_2]\otimes_{\mathbb{C}[H_1\times H_2]}(U_1\otimes U_2) \cong (\mathbb{C}G_1\otimes\mathbb{C}G_2)\otimes_{\mathbb{C}H_1\otimes\mathbb{C}H_2}(U_1\otimes U_2)$$

as left $\mathbb{C}[G_1\times G_2]$-modules.

Now, let us recall the isomorphism (13.112.1). It is an isomorphism of left $\mathbb{C}G_1\otimes\mathbb{C}G_2$-modules, and thus cannot be immediately combined with (13.112.12). However, it is easy to see that the corresponding isomorphism of left $\mathbb{C}[G_1\times G_2]$-modules holds as well: Namely, we have

$$(13.112.13)\qquad (\mathbb{C}G_1\otimes\mathbb{C}G_2)\otimes_{\mathbb{C}H_1\otimes\mathbb{C}H_2}(U_1\otimes U_2) \cong (\mathrm{Ind}_{\rho_1} U_1)\otimes(\mathrm{Ind}_{\rho_2} U_2)$$

as left $\mathbb{C}[G_1\times G_2]$-modules. Before we prove this, let us make three auxiliary observations which connect the left $\mathbb{C}[G_1\times G_2]$-module structures on the modules appearing in (13.112.13) with the left $\mathbb{C}G_1\otimes\mathbb{C}G_2$-module structures on the same modules:

- We have

$$(13.112.14)\qquad t_{(g_1,g_2)}m = (t_{g_1}\otimes t_{g_2})\,m \qquad \text{for every } (g_1,g_2)\in G_1\times G_2 \text{ and } m\in\mathbb{C}G_1\otimes\mathbb{C}G_2$$

  (where the expression $t_{(g_1,g_2)}m$ on the left hand side is defined using the left $\mathbb{C}[G_1\times G_2]$-module structure on $\mathbb{C}G_1\otimes\mathbb{C}G_2$, whereas the expression $(t_{g_1}\otimes t_{g_2})\,m$ on the right hand side is defined using the left $\mathbb{C}G_1\otimes\mathbb{C}G_2$-module structure on $\mathbb{C}G_1\otimes\mathbb{C}G_2$). This is easy to prove.
- We have

(13.112.15)

$$t_{(g_1,g_2)}n = (t_{g_1}\otimes t_{g_2})\,n \qquad \text{for every } (g_1,g_2)\in G_1\times G_2 \text{ and } n\in(\mathbb{C}G_1\otimes\mathbb{C}G_2)\otimes_{\mathbb{C}H_1\otimes\mathbb{C}H_2}(U_1\otimes U_2)$$

  (where the expression $t_{(g_1,g_2)}n$ on the left hand side is defined using the left $\mathbb{C}[G_1\times G_2]$-module structure on $(\mathbb{C}G_1\otimes\mathbb{C}G_2)\otimes_{\mathbb{C}H_1\otimes\mathbb{C}H_2}(U_1\otimes U_2)$, whereas the expression $(t_{g_1}\otimes t_{g_2})\,n$ on the right hand side is defined using the left $\mathbb{C}G_1\otimes\mathbb{C}G_2$-module structure on $(\mathbb{C}G_1\otimes\mathbb{C}G_2)\otimes_{\mathbb{C}H_1\otimes\mathbb{C}H_2}(U_1\otimes U_2)$). This is easy to prove using (13.112.14).

- Finally, we have

$$t_{(g_1,g_2)}m = (t_{g_1} \otimes t_{g_2}) m \qquad \text{for every } (g_1, g_2) \in G_1 \times G_2 \text{ and } m \in (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2) \tag{13.112.16}$$

(where the expression $t_{(g_1,g_2)}m$ on the left hand side is defined using the left $\mathbb{C}[G_1 \times G_2]$-module structure on $(\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)$, whereas the expression $(t_{g_1} \otimes t_{g_2}) m$ on the right hand side is defined using the left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-module structure on $(\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)$). Again, this is easy to check.

Now, it is easy to see that (13.112.13) holds[856].

Now, (13.112.12) becomes

$$\begin{aligned}&\mathbb{C}[G_1 \times G_2] \otimes_{\mathbb{C}[H_1 \times H_2]} (U_1 \otimes U_2)\\ &\cong (\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \cong (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2) \qquad (\text{by } (13.112.13))\end{aligned}$$

as left $\mathbb{C}[G_1 \times G_2]$-modules. Therefore,

$$\operatorname{Ind}_{\rho_1 \times \rho_2} (U_1 \otimes U_2) = \mathbb{C}[G_1 \times G_2] \otimes_{\mathbb{C}[H_1 \times H_2]} (U_1 \otimes U_2) \cong (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)$$

as left $\mathbb{C}[G_1 \times G_2]$-modules. This finishes the solution of Exercise 4.1.15.

13.113. **Solution to Exercise 4.1.16.** *Solution to Exercise 4.1.16.* In the following, we will use the following convention: Whenever K is a group, and k is an element of K, we shall write k for the element t_k of $\mathbb{C}K$. This is a relatively common abuse of notation, and it is harmless because the map $K \to \mathbb{C}K,\ k \mapsto t_k$ is an injective homomorphism of multiplicative monoids (so $t_{gh} = t_g t_h$ and $t_1 = 1$, which means that we won't run into ambiguities denoting t_k by k) and because every $\mathbb{C}K$-module M, every $m \in M$ and every $k \in K$ satisfy $km = t_k m$.

We solve the four parts of Exercise 4.1.16 in the following order: first, part (c); then, part (d); then, part (a); finally, part (b).

(c) The definition of $\operatorname{Res}_\rho V$ yields $\operatorname{Res}_\rho V = V$ as $\mathbb{C}$-vector spaces. Similarly, $\operatorname{Res}_\tau \operatorname{Res}_\rho V = \operatorname{Res}_\rho V$ as $\mathbb{C}$-vector spaces, and $\operatorname{Res}_{\rho\circ\tau} V = V$ as $\mathbb{C}$-vector spaces. Thus, $\operatorname{Res}_\tau \operatorname{Res}_\rho V = \operatorname{Res}_\rho V = V = \operatorname{Res}_{\rho\circ\tau} V$ as $\mathbb{C}$-vector spaces. But our goal is to show that $\operatorname{Res}_\tau \operatorname{Res}_\rho V = \operatorname{Res}_{\rho\circ\tau} V$ as $\mathbb{C}I$-modules. Thus, it suffices to prove that the left $\mathbb{C}I$-module structures on $\operatorname{Res}_\tau \operatorname{Res}_\rho V$ and $\operatorname{Res}_{\rho\circ\tau} V$ are identical. In other words, it

[856] *Proof of (13.112.13):* From (13.112.1), we conclude that there exists an isomorphism

$$\mathbf{T} : (\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \to (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)$$

of left $\mathbb{C}G_1 \otimes \mathbb{C}G_2$-modules. We shall now show that this map $\mathbf{T}$ is an isomorphism of left $\mathbb{C}[G_1 \times G_2]$-modules as well. In order to do so, it is sufficient to show that the map $\mathbf{T}$ is a homomorphism of left $\mathbb{C}[G_1 \times G_2]$-modules (because we already know that $\mathbf{T}$ is invertible). In other words, it is sufficient to show that

$$\mathbf{T}(an) = a\mathbf{T}(n) \tag{13.112.17}$$

for every $a \in \mathbb{C}[G_1 \times G_2]$ and $n \in (\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2)$ (since we already know that the map $\mathbf{T}$ is $\mathbb{C}$-linear).

Proof of (13.112.17): Let $a \in \mathbb{C}[G_1 \times G_2]$ and $n \in (\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2)$. We need to prove the equality $\mathbf{T}(an) = a\mathbf{T}(n)$. This equality is $\mathbb{C}$-linear in a. Hence, we can WLOG assume that a belongs to the basis $\left(t_{(g_1,g_2)}\right)_{(g_1,g_2)\in G_1\times G_2}$ of the $\mathbb{C}$-vector space $\mathbb{C}[G_1 \times G_2]$. Assume this. Thus, $a = t_{(g_1,g_2)}$ for some $(g_1, g_2) \in G_1 \times G_2$. Consider this (g_1, g_2). We have $\underbrace{a}_{=t_{(g_1,g_2)}} n = t_{(g_1,g_2)}n = (t_{g_1} \otimes t_{g_2}) n$ (by (13.112.15)). Applying the map $\mathbf{T}$ to both sides of this equality, we obtain

$$\mathbf{T}(an) = \mathbf{T}((t_{g_1} \otimes t_{g_2}) n) = (t_{g_1} \otimes t_{g_2}) \mathbf{T}(n) \qquad (\text{since } \mathbf{T} \text{ is a homomorphism of left } \mathbb{C}G_1 \otimes \mathbb{C}G_2\text{-modules}).$$

Compared with

$$\underbrace{a}_{=t_{(g_1,g_2)}} \mathbf{T}(n) = t_{(g_1,g_2)}\mathbf{T}(n) = (t_{g_1} \otimes t_{g_2}) \mathbf{T}(n) \qquad (\text{by } (13.112.16), \text{ applied to } m = \mathbf{T}(n)),$$

this yields $\mathbf{T}(an) = a\mathbf{T}(n)$. This proves (13.112.17).

Now, (13.112.17) shows that $\mathbf{T}$ is a homomorphism of left $\mathbb{C}[G_1 \times G_2]$-modules (since $\mathbf{T}$ is $\mathbb{C}$-linear), and therefore an isomorphism of left $\mathbb{C}[G_1 \times G_2]$-modules (since $\mathbf{T}$ is invertible). Thus, $(\mathbb{C}G_1 \otimes \mathbb{C}G_2) \otimes_{\mathbb{C}H_1 \otimes \mathbb{C}H_2} (U_1 \otimes U_2) \cong (\operatorname{Ind}_{\rho_1} U_1) \otimes (\operatorname{Ind}_{\rho_2} U_2)$ as left $\mathbb{C}[G_1 \times G_2]$-modules. This proves (13.112.13).

suffices to show that every $i \in \mathbb{C}I$ and $v \in V$ satisfy the equality

$$\begin{aligned}&(\text{the action of } i \in \mathbb{C}I \text{ on the element } v \text{ of the left } \mathbb{C}I\text{-module } \operatorname{Res}_\tau \operatorname{Res}_\rho V) \\ &= (\text{the action of } i \in \mathbb{C}I \text{ on the element } v \text{ of the left } \mathbb{C}I\text{-module } \operatorname{Res}_{\rho\circ\tau} V).\end{aligned} \tag{13.113.1}$$

(Of course, both sides of the equality (13.113.1) could be rewritten as iv, but this notation is ambiguous, because i simultaneously belongs to two $\mathbb{C}I$-modules $\operatorname{Res}_\tau \operatorname{Res}_\rho V$ and $\operatorname{Res}_{\rho\circ\tau} V$ which are not yet known to be identical.)

Proof of (13.113.1): Let $i \in \mathbb{C}I$ and $v \in V$. We need to prove the equality (13.113.1). Since this equality is $\mathbb{C}$-linear in i, we can WLOG assume that i belongs to the basis I of the $\mathbb{C}$-vector space $\mathbb{C}I$. Assume this. Now, the definition of the left $\mathbb{C}I$-module $\operatorname{Res}_\tau \operatorname{Res}_\rho V$ yields

$$\begin{aligned}&(\text{the action of } i \in \mathbb{C}I \text{ on the element } v \text{ of the left } \mathbb{C}I\text{-module } \operatorname{Res}_\tau \operatorname{Res}_\rho V) \\ &= (\text{the action of } \tau(i) \in \mathbb{C}H \text{ on the element } v \text{ of the left } \mathbb{C}H\text{-module } \operatorname{Res}_\rho V) \\ &= \left(\text{the action of } \underbrace{\rho(\tau(i))}_{=(\rho\circ\tau)(i)} \in \mathbb{C}G \text{ on the element } v \text{ of the left } \mathbb{C}G\text{-module } V\right) \\ &\qquad (\text{by the definition of the left } \mathbb{C}H\text{-module } \operatorname{Res}_\rho V) \\ &= (\text{the action of } (\rho\circ\tau)(i) \in \mathbb{C}G \text{ on the element } v \text{ of the left } \mathbb{C}G\text{-module } V).\end{aligned}$$

Compared with

$$\begin{aligned}&(\text{the action of } i \in \mathbb{C}I \text{ on the element } v \text{ of the left } \mathbb{C}I\text{-module } \operatorname{Res}_{\rho\circ\tau} V) \\ &= (\text{the action of } (\rho\circ\tau)(i) \in \mathbb{C}G \text{ on the element } v \text{ of the left } \mathbb{C}G\text{-module } V) \\ &\qquad (\text{by the definition of the left } \mathbb{C}I\text{-module } \operatorname{Res}_{\rho\circ\tau} V),\end{aligned}$$

this yields

$$\begin{aligned}&(\text{the action of } i \in \mathbb{C}I \text{ on the element } v \text{ of the left } \mathbb{C}I\text{-module } \operatorname{Res}_\tau \operatorname{Res}_\rho V) \\ &= (\text{the action of } i \in \mathbb{C}I \text{ on the element } v \text{ of the left } \mathbb{C}I\text{-module } \operatorname{Res}_{\rho\circ\tau} V).\end{aligned}$$

This proves (13.113.1).

Now, we know that $\operatorname{Res}_\tau \operatorname{Res}_\rho V = \operatorname{Res}_{\rho\circ\tau} V$ as $\mathbb{C}$-vector spaces. Thus, (13.113.1) shows that $\operatorname{Res}_\tau \operatorname{Res}_\rho V = \operatorname{Res}_{\rho\circ\tau} V$ as left $\mathbb{C}I$-modules as well. Exercise 4.1.16(c) is thus solved.

(d) Let $f \in R_{\mathbb{C}}(G)$. The definition of $\operatorname{Res}_{\rho\circ\tau} f$ yields $\operatorname{Res}_{\rho\circ\tau} f = f \circ (\rho \circ \tau)$. But the definition of $\operatorname{Res}_\rho f$ yields $\operatorname{Res}_\rho f = f \circ \rho$. The definition of $\operatorname{Res}_\tau \operatorname{Res}_\rho f$ yields

$$\operatorname{Res}_\tau \operatorname{Res}_\rho f = \underbrace{(\operatorname{Res}_\rho f)}_{=f\circ\rho} \circ \tau = (f\circ\rho)\circ\tau = f\circ(\rho\circ\tau) = \operatorname{Res}_{\rho\circ\tau} f.$$

This solves Exercise 4.1.16(d).

(a) Let U be any $\mathbb{C}I$-module.

Recall that $\operatorname{Ind}_\tau U$ is defined as the $\mathbb{C}H$-module $\mathbb{C}H \otimes_{\mathbb{C}I} U$, where $\mathbb{C}H$ is regarded as a $(\mathbb{C}H, \mathbb{C}I)$-bimodule according to the following rule: The left $\mathbb{C}H$-module structure on $\mathbb{C}H$ is plain multiplication inside $\mathbb{C}H$; the right $\mathbb{C}I$-module structure on $\mathbb{C}H$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\tau] : \mathbb{C}I \to \mathbb{C}H$ (thus, it is explicitly given by $\gamma\eta = \gamma \cdot (\mathbb{C}[\tau])\,\eta$ for all $\gamma \in \mathbb{C}H$ and $\eta \in \mathbb{C}I$).

Furthermore, $\operatorname{Ind}_\rho(\operatorname{Ind}_\tau U)$ is defined as the $\mathbb{C}G$-module $\mathbb{C}G \otimes_{\mathbb{C}H} (\operatorname{Ind}_\tau U)$, where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}H)$-bimodule according to the following rule: The left $\mathbb{C}G$-module structure on $\mathbb{C}G$ is plain multiplication inside $\mathbb{C}G$; the right $\mathbb{C}H$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho] : \mathbb{C}H \to \mathbb{C}G$ (thus, it is explicitly given by $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho])\,\eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}H$).

Finally, $\operatorname{Ind}_{\rho\circ\tau} U$ is defined as the $\mathbb{C}G$-module $\mathbb{C}G \otimes_{\mathbb{C}I} U$, where $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}I)$-bimodule according to the following rule: The left $\mathbb{C}G$-module structure on $\mathbb{C}G$ is plain multiplication inside $\mathbb{C}G$; the right $\mathbb{C}I$-module structure on $\mathbb{C}G$ is induced by the $\mathbb{C}$-algebra homomorphism $\mathbb{C}[\rho\circ\tau] : \mathbb{C}I \to \mathbb{C}G$ (thus, it is explicitly given by $\gamma\eta = \gamma \cdot (\mathbb{C}[\rho\circ\tau])\,\eta$ for all $\gamma \in \mathbb{C}G$ and $\eta \in \mathbb{C}I$).

Thus, we have introduced a $(\mathbb{C}H, \mathbb{C}I)$-bimodule structure on $\mathbb{C}H$, a $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure on $\mathbb{C}G$ and a $(\mathbb{C}G, \mathbb{C}I)$-bimodule structure on $\mathbb{C}G$. The left $\mathbb{C}G$-module structure that underlies the $(\mathbb{C}G, \mathbb{C}H)$-bimodule structure on $\mathbb{C}G$ is identical with the left $\mathbb{C}G$-module structure that underlies the $(\mathbb{C}G, \mathbb{C}I)$-bimodule structure on $\mathbb{C}G$ (because both of these left $\mathbb{C}G$-module structures are defined to be plain multiplication inside $\mathbb{C}G$). Therefore, we will not run into ambiguities if we write expressions such as ab for $a \in \mathbb{C}G$ and $b \in \mathbb{C}G$.

We shall now show that

$$\mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H \cong \mathbb{C}G \qquad \text{as } (\mathbb{C}G, \mathbb{C}I)\text{-bimodules.} \tag{13.113.2}$$

(Here, on the left hand side, $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}H)$-bimodule and $\mathbb{C}H$ is regarded as $(\mathbb{C}H, \mathbb{C}I)$-bimodule, whereas on the right hand side, $\mathbb{C}G$ is regarded as a $(\mathbb{C}G, \mathbb{C}I)$-bimodule.)

Proof of (13.113.2): There is clearly a unique $\mathbb{C}$-vector space isomorphism $\Phi : \mathbb{C}G \to \mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H$ which satisfies

$$(\Phi(m) = m \otimes_{\mathbb{C}H} 1_{\mathbb{C}H} \qquad \text{for all } m \in \mathbb{C}G). \tag{13.113.3}$$

[857] Consider this Φ. It is straightforward to see that Φ is a homomorphism of left G-sets and a homomorphism of right I-sets. Hence, Φ is a homomorphism of $(\mathbb{C}G, \mathbb{C}I)$-bimodules (since Φ is $\mathbb{C}$-linear), thus an isomorphism of $(\mathbb{C}G, \mathbb{C}I)$-bimodules (since Φ is invertible). Therefore, there exists an isomorphism of $(\mathbb{C}G, \mathbb{C}I)$-bimodules from $\mathbb{C}G$ to $\mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H$ (namely, Φ). In other words, $\mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H \cong \mathbb{C}G$ as $(\mathbb{C}G, \mathbb{C}I)$-bimodules. This proves (13.113.2).

Now,

$$\begin{aligned}
\operatorname{Ind}_\rho (\operatorname{Ind}_\tau U) &= \mathbb{C}G \otimes_{\mathbb{C}H} \underbrace{(\operatorname{Ind}_\tau U)}_{=\mathbb{C}H \otimes_{\mathbb{C}I} U} = \mathbb{C}G \otimes_{\mathbb{C}H} (\mathbb{C}H \otimes_{\mathbb{C}I} U) \\
&\cong \underbrace{(\mathbb{C}G \otimes_{\mathbb{C}H} \mathbb{C}H)}_{\substack{\cong \mathbb{C}G \text{ as } (\mathbb{C}G, \mathbb{C}I)\text{-bimodules} \\ \text{(by (13.113.2))}}} \otimes_{\mathbb{C}I} U \qquad \text{(by the associativity of the tensor product)} \\
&\cong \mathbb{C}G \otimes_{\mathbb{C}I} U = \operatorname{Ind}_{\rho \circ \tau} U \qquad \left(\text{since } \operatorname{Ind}_{\rho \circ \tau} U = \mathbb{C}G \otimes_{\mathbb{C}I} U \text{ as left } \mathbb{C}G\text{-modules}\right)
\end{aligned}$$

as left $\mathbb{C}G$-modules. This solves Exercise 4.1.16(a).

(b) *First solution to Exercise 4.1.16(b).* Let $f \in R_{\mathbb{C}}(I)$. Every $r \in H$ satisfies

$$\begin{aligned}
(\operatorname{Ind}_\tau f)(r) &= \frac{1}{|I|} \sum_{\substack{(h,k) \in I \times H; \\ k\tau(h)k^{-1} = r}} f(h) \qquad \left(\text{by the definition of } \operatorname{Ind}_\tau f\right) \\
&= \frac{1}{|I|} \underbrace{\sum_{\substack{(i,v) \in I \times H; \\ v\tau(i)v^{-1} = r}}}_{= \sum_{i \in I} \sum_{\substack{v \in H; \\ v\tau(i)v^{-1} = r}}} f(i) \qquad \left(\text{here, we renamed the summation index } (h,k) \text{ as } (i,v)\right) \\
&= \frac{1}{|I|} \sum_{i \in I} \sum_{\substack{v \in H; \\ v\tau(i)v^{-1} = r}} f(i).
\end{aligned} \tag{13.113.4}$$

[857] Indeed, this is a particular case of the following fundamental fact from linear algebra: If A is a $\mathbb{C}$-algebra, and if M is a right A-module, then there is a unique $\mathbb{C}$-vector space isomorphism $\Phi : M \to M \otimes_A A$ which satisfies

$$(\Phi(m) = m \otimes_A 1_A \qquad \text{for all } m \in M).$$

Now, let $g \in G$. Then, the definition of $\operatorname{Ind}_\rho\left(\operatorname{Ind}_\tau f\right)$ yields

$$\left(\operatorname{Ind}_\rho\left(\operatorname{Ind}_\tau f\right)\right)(g) = \frac{1}{|H|} \sum_{\substack{(h,k)\in H\times G;\\ k\rho(h)k^{-1}=g}} \left(\operatorname{Ind}_\tau f\right)(h) = \frac{1}{|H|} \underbrace{\sum_{\substack{(r,k)\in H\times G;\\ k\rho(r)k^{-1}=g}}}_{=\sum_{k\in G} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}}} \underbrace{\left(\operatorname{Ind}_\tau f\right)(r)}_{\substack{=\frac{1}{|I|}\sum_{i\in I}\sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}} f(i)\\ \text{(by (13.113.4))}}}$$

$$\text{(here, we renamed the summation index } (h,k) \text{ as } (r,k)\text{)}$$

$$= \frac{1}{|H|} \sum_{k\in G} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}} \frac{1}{|I|} \sum_{i\in I} \sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}} f(i)$$

$$= \frac{1}{|I|}\frac{1}{|H|} \sum_{k\in G} \underbrace{\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}} \sum_{i\in I}}_{=\sum_{i\in I} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}}} \sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}} f(i)$$

$$= \frac{1}{|I|}\frac{1}{|H|} \sum_{k\in G} \sum_{i\in I} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}} \sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}} f(i). \tag{13.113.5}$$

But every $k \in G$ and $i \in I$ satisfy

$$\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}} \sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}} f(i) = \sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i) \tag{13.113.6}$$

[858].

[858] *Proof of (13.113.6):* Let $k \in G$ and $i \in I$. We must prove (13.113.6). We have

$$\underbrace{\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}} \sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}}}_{=\sum_{v\in H} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}}} f(i)$$

$$= \sum_{v\in H} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i) = \sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i) + \sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}\neq g}} \sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i) \tag{13.113.7}$$

(because every $v \in H$ satisfies either $k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1} = g$ or $k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1} \neq g$, but never both).

Now, we shall show that

$$\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i) = 0 \tag{13.113.8}$$

for every $v \in H$ which satisfies $k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1} \neq g$.

Proof of (13.113.8): Let $v \in H$ be such that $k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1} \neq g$. If some $r \in H$ satisfies $k\rho(r)k^{-1} = g$ and $v\tau(i)v^{-1} = r$, then this r must satisfy

$$k\rho(v)\cdot\rho(\tau(i))\cdot\underbrace{(k\rho(v))^{-1}}_{=(\rho(v))^{-1}k^{-1}} = k\underbrace{\rho(v)\cdot\rho(\tau(i))\cdot(\rho(v))^{-1}}_{\substack{=\rho\left(v\tau(i)v^{-1}\right)\\ \text{(since } \rho \text{ is a group}\\ \text{homomorphism)}}}k^{-1}$$

$$= k\rho\left(\underbrace{v\tau(i)v^{-1}}_{=r}\right)k^{-1} = k\rho(r)k^{-1} = g,$$

which contradicts $k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}\neq g$. Hence, we have obtained a contradiction for every $r\in H$ which satisfies $k\rho(r)k^{-1}=g$ and $v\tau(i)v^{-1}=r$. Thus, there exists no $r\in H$ which satisfies $k\rho(r)k^{-1}=g$ and $v\tau(i)v^{-1}=r$. Therefore, the sum $\sum\limits_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i)$ is an empty sum, and thus its value is 0. This proves (13.113.8).

On the other hand, let us show that

$$\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i)=f(i) \tag{13.113.9}$$

for every $v\in H$ which satisfies $k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g$.

Proof of (13.113.9): Let $v\in H$ be such that $k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g$. If some $r\in H$ satisfies $k\rho(r)k^{-1}=g$ and $v\tau(i)v^{-1}=r$, then this r must equal $v\tau(i)v^{-1}$ (because $v\tau(i)v^{-1}=r$). Hence, there exists **at most one** $r\in H$ which satisfies $k\rho(r)k^{-1}=g$ and $v\tau(i)v^{-1}=r$.

On the other hand, the element $v\tau(i)v^{-1}$ of H satisfies

$$k\underbrace{\rho\left(v\tau(i)v^{-1}\right)}_{\substack{=\rho(v)\cdot\rho(\tau(i))\cdot\rho(v)^{-1}\\ \text{(since }\rho\text{ is a group}\\ \text{homomorphism)}}}k^{-1}=k\rho(v)\cdot\rho(\tau(i))\cdot\underbrace{\rho(v)^{-1}k^{-1}}_{=(k\rho(v))^{-1}}=k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g$$

and $v\tau(i)v^{-1}=v\tau(i)v^{-1}$. In other words, $v\tau(i)v^{-1}$ is an element $r\in H$ which satisfies $k\rho(r)k^{-1}=g$ and $v\tau(i)v^{-1}=r$. Hence, there exists **at least one** $r\in H$ which satisfies $k\rho(r)k^{-1}=g$ and $v\tau(i)v^{-1}=r$ (namely, $v\tau(i)v^{-1}$). Since we also have shown that there exists **at most one** such $r\in H$, we can thus conclude that there exists **exactly one** $r\in H$ which satisfies $k\rho(r)k^{-1}=g$ and $v\tau(i)v^{-1}=r$. In other words, the sum $\sum\limits_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i)$ has precisely one addend. Hence, this sum rewrites as follows: $\sum\limits_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i)=f(i)$. This proves (13.113.9).

Now, (13.113.7) becomes

$$\begin{aligned}
&\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}}\ \sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}} f(i)\\
&=\sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}}\ \underbrace{\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i)}_{\substack{=f(i)\\ \text{(by (13.113.9))}}}+\sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}\neq g}}\ \underbrace{\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g;\\ v\tau(i)v^{-1}=r}} f(i)}_{\substack{=0\\ \text{(by (13.113.8))}}}\\
&=\sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i)+\underbrace{\sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}\neq g}} 0}_{=0}=\sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i)\,.
\end{aligned}$$

This proves (13.113.6).

Thus, (13.113.5) becomes

$$\begin{aligned}
&\left(\operatorname{Ind}_\rho\left(\operatorname{Ind}_\tau f\right)\right)(g)\\
&= \frac{1}{|I|}\frac{1}{|H|} \underbrace{\sum_{k\in G}\sum_{i\in I}}_{=\sum_{i\in I}\sum_{k\in G}} \underbrace{\sum_{\substack{r\in H;\\ k\rho(r)k^{-1}=g}} \sum_{\substack{v\in H;\\ v\tau(i)v^{-1}=r}} f(i)}_{\substack{=\sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i)\\ \text{(by (13.113.6))}}}\\
&= \frac{1}{|I|}\frac{1}{|H|}\sum_{i\in I} \underbrace{\sum_{k\in G}\sum_{\substack{v\in H;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}}}_{=\sum_{v\in H}\sum_{\substack{k\in G;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}}} f(i)\\
&= \frac{1}{|I|}\frac{1}{|H|}\sum_{i\in I}\sum_{v\in H}\sum_{\substack{k\in G;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i).
\end{aligned}\tag{13.113.10}$$

However, for every $i\in I$ and $v\in H$, we have

$$\sum_{\substack{k\in G;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i) = \sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}} f(i) \tag{13.113.11}$$

[859].

Thus, (13.113.10) becomes

$$\begin{aligned}
&\left(\operatorname{Ind}_\rho\left(\operatorname{Ind}_\tau f\right)\right)(g)\\
&= \frac{1}{|I|}\frac{1}{|H|}\sum_{i\in I}\sum_{v\in H} \underbrace{\sum_{\substack{k\in G;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i)}_{\substack{=\sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}} f(i)\\ \text{(by (13.113.11))}}} = \frac{1}{|I|}\frac{1}{|H|}\sum_{i\in I} \underbrace{\sum_{v\in H}\sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}} f(i)}_{=|H|\sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}} f(i)}\\
&= \frac{1}{|I|}\frac{1}{|H|}\sum_{i\in I}|H|\sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}} f(i) = \frac{1}{|I|}\underbrace{\frac{1}{|H|}|H|}_{=1} \underbrace{\sum_{i\in I}\sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}}}_{\substack{=\sum_{\substack{(i,k)\in I\times G;\\ k\rho(\tau(i))k^{-1}=g}} = \sum_{\substack{(i,k)\in I\times G;\\ k(\rho\circ\tau)(i)k^{-1}=g}}\\ \text{(since } \rho(\tau(i))=(\rho\circ\tau)(i))}} f(i)\\
&= \frac{1}{|I|}\sum_{\substack{(i,k)\in I\times G;\\ k(\rho\circ\tau)(i)k^{-1}=g}} f(i) = \frac{1}{|I|}\sum_{\substack{(h,k)\in I\times G;\\ k(\rho\circ\tau)(h)k^{-1}=g}} f(h)\\
&\qquad\text{(here, we renamed the summation index } (i,k) \text{ as } (h,k)).
\end{aligned}$$

[859] *Proof of (13.113.11):* Let $i\in I$ and $v\in H$. We have $\rho(v)\in G$. Therefore, the map $G\to G,\ k\mapsto k\rho(v)$ is a bijection (since G is a group). Therefore, we can substitute $k\rho(v)$ for k in the sum $\sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}} f(i)$. We thus obtain

$$\sum_{\substack{k\in G;\\ k\rho(\tau(i))k^{-1}=g}} f(i) = \sum_{\substack{k\in G;\\ k\rho(v)\rho(\tau(i))(k\rho(v))^{-1}=g}} f(i) = \sum_{\substack{k\in G;\\ k\rho(v)\cdot\rho(\tau(i))\cdot(k\rho(v))^{-1}=g}} f(i).$$

This proves (13.113.11).

Compared with

$$\left(\operatorname{Ind}_{\rho\circ\tau} f\right)(g) = \frac{1}{|I|} \sum_{\substack{(h,k)\in I\times G;\\ k(\rho\circ\tau)(h)k^{-1}=g}} f(h) \qquad \left(\text{by the definition of } \left(\operatorname{Ind}_{\rho\circ\tau} f\right)(g)\right),$$

this yields $\left(\operatorname{Ind}_\rho\left(\operatorname{Ind}_\tau f\right)\right)(g) = \left(\operatorname{Ind}_{\rho\circ\tau} f\right)(g)$.

Let us now forget that we fixed g. We thus have shown that $\left(\operatorname{Ind}_\rho\left(\operatorname{Ind}_\tau f\right)\right)(g) = \left(\operatorname{Ind}_{\rho\circ\tau} f\right)(g)$ for every $g \in G$. In other words, $\operatorname{Ind}_\rho \operatorname{Ind}_\tau f = \operatorname{Ind}_{\rho\circ\tau} f$. This solves Exercise 4.1.16(b).

Second solution to Exercise 4.1.16(b). We shall now give an alternative solution of Exercise 4.1.16(b) which relies on Exercise 4.1.16(d) and a certain fact about class functions:

Lemma 13.113.1. *Let G be a finite group. Let $u \in R_{\mathbb{C}}(G)$. Assume that every $v \in R_{\mathbb{C}}(G)$ satisfies $\langle u, v\rangle_G = 0$. Then, $u = 0$.*

Proof of Lemma 13.113.1. Let us use the Iverson bracket notation; that is, for any statement $\mathcal{A}$, we define $[\mathcal{A}]$ to be the integer $\begin{cases} 1, & \text{if } \mathcal{A} \text{ is true;} \\ 0, & \text{if } \mathcal{A} \text{ is false} \end{cases}$.

Fix an element $h \in G$. We define a map $\alpha_h : G \to \mathbb{C}$ by

$$\left(\alpha_h(g) = \sum_{k\in G} \left[khk^{-1} = g\right] \qquad \text{for every } g \in G\right).$$

(Notice that this map α_h is identical with the map $\alpha_{G,h}$ defined in Exercise 4.4.3, but we will not use this.) Then, $\alpha_h \in R_{\mathbb{C}}(G)$ [860]. Hence, $\langle u, \alpha_h\rangle_G$ is well-defined. But recall that every $v \in R_{\mathbb{C}}(G)$ satisfies

[860] *Proof.* Let p and q be two conjugate elements of G. Then, there exists some $r \in G$ such that $p = rqr^{-1}$ (since p and q are conjugate). Consider this r. The definition of α_h yields

$$\alpha_h(p) = \sum_{k\in G} \left[khk^{-1} = \underbrace{p}_{=rqr^{-1}}\right] = \sum_{k\in G} \left[\underbrace{khk^{-1} = rqr^{-1}}_{\substack{\text{this is equivalent to} \\ (r^{-1}khk^{-1}r=q)}}\right] = \sum_{k\in G} \left[r^{-1}khk^{-1}r = q\right].$$

Now, recall that $r \in G$. Hence, the map $G \to G,\ k \mapsto rk$ is a bijection (since G is a group). Hence, we can substitute rk for k in the sum $\sum_{k\in G} \left[r^{-1}khk^{-1}r = q\right]$. We thus obtain

$$\begin{aligned} \sum_{k\in G} \left[r^{-1}khk^{-1}r = q\right] &= \sum_{k\in G} \left[r^{-1}rkh \underbrace{(rk)^{-1}}_{=k^{-1}r^{-1}} r = q\right] = \sum_{k\in G} \left[\underbrace{r^{-1}r}_{=1} khk^{-1} \underbrace{r^{-1}r}_{=1} = q\right] \\ &= \sum_{k\in G} \left[khk^{-1} = q\right] = \alpha_h(q) \end{aligned}$$

(since $\alpha_h(q) = \sum_{k\in G} \left[khk^{-1} = q\right]$ (by the definition of α_h)). Hence, $\alpha_h(p) = \sum_{k\in G} \left[r^{-1}khk^{-1}r = q\right] = \alpha_h(q)$.

Let us now forget that we fixed p and q. We thus have shown that $\alpha_h(p) = \alpha_h(q)$ whenever p and q are two conjugate elements of G. In other words, the function α_h is constant on G-conjugacy classes. In other words, α_h is a class function on G (because the class functions on G are defined to be the functions $G \to \mathbb{C}$ which are constant on G-conjugacy classes). In other words, $\alpha_h \in R_{\mathbb{C}}(G)$ (since $R_{\mathbb{C}}(G)$ is the set of all class functions on G). Qed.

$\langle u, v\rangle_G = 0$. Applying this to $v = \alpha_h$, we obtain $\langle u, \alpha_h\rangle_G = 0$. Thus,

$$0 = \langle u, \alpha_h\rangle_G = \frac{1}{|G|} \sum_{g\in G} u(g) \underbrace{\alpha_h\left(g^{-1}\right)}_{\substack{=\sum_{k\in G}\left[khk^{-1}=g^{-1}\right] \\ \text{(by the definition of } \alpha_h\text{)}}} \qquad \text{(by the definition of the bilinear form } \langle\cdot,\cdot\rangle_G\text{)}$$

$$= \frac{1}{|G|} \sum_{g\in G} u(g) \sum_{k\in G} \left[khk^{-1} = g^{-1}\right] = \frac{1}{|G|} \sum_{k\in G} \sum_{g\in G} u(g) \left[\underbrace{khk^{-1} = g^{-1}}_{\text{this is equivalent to } \left(g=\left(khk^{-1}\right)^{-1}\right)}\right]$$

$$= \frac{1}{|G|} \sum_{k\in G} \sum_{g\in G} u(g) \left[g = \left(khk^{-1}\right)^{-1}\right]. \tag{13.113.12}$$

But every $k \in G$ satisfies

$$\sum_{g\in G} u(g) \left[g = \left(khk^{-1}\right)^{-1}\right] = u\left(h^{-1}\right) \tag{13.113.13}$$

[861]. Hence, (13.113.12) becomes

$$0 = \frac{1}{|G|} \sum_{k\in G} \underbrace{\sum_{g\in G} u(g) \left[g = \left(khk^{-1}\right)^{-1}\right]}_{\substack{=u\left(h^{-1}\right) \\ \text{(by (13.113.13))}}} = \frac{1}{|G|} \underbrace{\sum_{k\in G} u\left(h^{-1}\right)}_{=|G|u\left(h^{-1}\right)} = \frac{1}{|G|} |G| u\left(h^{-1}\right) = u\left(h^{-1}\right).$$

Thus, $u\left(h^{-1}\right) = 0$.

Let us now forget that we fixed h. We thus have shown that

$$u\left(h^{-1}\right) = 0 \qquad \text{for every } h \in G. \tag{13.113.15}$$

Let us now fix $h \in G$. Then, (13.113.15) (applied to h^{-1} instead of h) yields $u\left(\left(h^{-1}\right)^{-1}\right) = 0$. In other words, $u(h) = 0$ (since $\left(h^{-1}\right)^{-1} = h$).

Let us now forget that we fixed h. We thus have shown that $u(h) = 0$ for every $h \in G$. In other words, $u = 0$. This proves Lemma 13.113.1. □

[861] *Proof of (13.113.13):* Let us first recall that u belongs to the set $R_{\mathbb{C}}(G)$. In other words, u is a class function on G (since $R_{\mathbb{C}}(G)$ is the set of all class functions on G). In other words, the function u is constant on G-conjugacy classes (because the class functions on G are defined to be the functions $G \to \mathbb{C}$ which are constant on G-conjugacy classes). In other words,

$$u(p) = u(q) \tag{13.113.14}$$

whenever p and q are two conjugate elements of G.

Now, let $k \in G$. Then, the elements $kh^{-1}k^{-1}$ and h^{-1} of G are conjugate. Hence, $u\left(kh^{-1}k^{-1}\right) = u\left(h^{-1}\right)$ (by (13.113.14), applied to $p = kh^{-1}k^{-1}$ and $q = h^{-1}$).

All addends of the sum $\sum_{g\in G} u(g) \left[g = \left(khk^{-1}\right)^{-1}\right]$ are zero except for the addend for $g = \left(khk^{-1}\right)^{-1}$ (because the factor $\left[g = \left(khk^{-1}\right)^{-1}\right]$ is zero unless $g = \left(khk^{-1}\right)^{-1}$). Hence, this sum simplifies as follows:

$$\sum_{g\in G} u(g) \left[g = \left(khk^{-1}\right)^{-1}\right] = u\left(\underbrace{\left(khk^{-1}\right)^{-1}}_{=kh^{-1}k^{-1}}\right) \underbrace{\left[\left(khk^{-1}\right)^{-1} = \left(khk^{-1}\right)^{-1}\right]}_{=1} = u\left(kh^{-1}k^{-1}\right) = u\left(h^{-1}\right).$$

This proves (13.113.13).

Now, let us return to solving Exercise 4.1.16(b). Let $f \in R_{\mathbb{C}}(I)$. Let $v \in R_{\mathbb{C}}(G)$. Then,

$$\begin{aligned}
\left\langle \operatorname{Ind}_\rho \operatorname{Ind}_\tau f, v \right\rangle_G &= \left\langle \operatorname{Ind}_\tau f, \operatorname{Res}_\rho v \right\rangle_H \qquad \text{(by (4.1.17), applied to } \alpha = \operatorname{Ind}_\tau f \text{ and } \beta = v\text{)} \\
&= \left\langle f, \underbrace{\operatorname{Res}_\tau \operatorname{Res}_\rho v}_{\substack{= \operatorname{Res}_{\rho\circ\tau} v \\ \text{(by Exercise 4.1.16(d),} \\ \text{applied to } v \text{ instead of } f\text{)}}} \right\rangle_I \\
&\qquad \text{(by (4.1.17), applied to } H,\ I,\ \tau,\ f \text{ and } \operatorname{Res}_\rho v \text{ instead of } G,\ H,\ \rho,\ \alpha \text{ and } \beta\text{)} \\
&= \left\langle f, \operatorname{Res}_{\rho\circ\tau} v \right\rangle_I .
\end{aligned}$$

Compared with

$$\left\langle \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G = \left\langle f, \operatorname{Res}_{\rho\circ\tau} v \right\rangle_I \qquad \text{(by (4.1.17), applied to } I,\ \rho\circ\tau,\ f \text{ and } v \text{ instead of } H,\ \rho,\ \alpha \text{ and } \beta\text{)},$$

this yields $\left\langle \operatorname{Ind}_\rho \operatorname{Ind}_\tau f, v \right\rangle_G = \left\langle \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G$. Now, the form $\left\langle \cdot, \cdot \right\rangle_G$ is $\mathbb{C}$-bilinear, and therefore we have

$$\left\langle \operatorname{Ind}_\rho \operatorname{Ind}_\tau f - \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G = \underbrace{\left\langle \operatorname{Ind}_\rho \operatorname{Ind}_\tau f, v \right\rangle_G}_{= \left\langle \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G} - \left\langle \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G = \left\langle \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G - \left\langle \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G = 0.$$

Now, let us forget that we fixed v. We thus have shown that every $v \in R_{\mathbb{C}}(G)$ satisfies $\left\langle \operatorname{Ind}_\rho \operatorname{Ind}_\tau f - \operatorname{Ind}_{\rho\circ\tau} f, v \right\rangle_G = 0$. Hence, Lemma 13.113.1 (applied to $u = \operatorname{Ind}_\rho \operatorname{Ind}_\tau f - \operatorname{Ind}_{\rho\circ\tau} f$) yields $\operatorname{Ind}_\rho \operatorname{Ind}_\tau f - \operatorname{Ind}_{\rho\circ\tau} f = 0$. Thus, $\operatorname{Ind}_\rho \operatorname{Ind}_\tau f = \operatorname{Ind}_{\rho\circ\tau} f$. This solves Exercise 4.1.16(b) again.

[*Remark:* Recall that Exercise 4.1.14 (specifically, its parts (c), (d), (e) and (f)) shows that ρ-induction (of modules and of class functions) generalizes both the usual notion of induction and the fixed point construction. More precisely, ρ-induction becomes usual induction (at least up to isomorphism) when ρ is injective, and becomes fixed point construction when ρ is surjective. Exercise 4.1.16 (specifically, its parts (a) and (b)), on the other hand, shows that in the general case, ρ-induction can be reduced to a composition of usual induction and fixed point construction, because every group homomorphism $\rho : H \to G$ can be factored as a composition $\alpha \circ \beta$ of a surjective group homomorphism $\beta : H \to \overline{H}$ with an injective group homomorphism $\alpha : \overline{H} \to G$. This allows some alternative proofs of some parts of Exercise 4.1.14, which the interested reader can find.]

13.114. **Solution to Exercise 4.2.3.** *Solution to Exercise 4.2.3.* We need to prove that

$$\operatorname{Ind}_{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}} \left(\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j}^{\mathfrak{S}_{i+j}} (U \otimes V) \otimes W \right) \cong \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}} (U \otimes V \otimes W) \tag{13.114.1}$$

and

$$\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_{j+k}}^{\mathfrak{S}_{i+j+k}} \left(U \otimes \operatorname{Ind}_{\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{j+k}} (V \otimes W) \right) \cong \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}} (U \otimes V \otimes W) \tag{13.114.2}$$

as $\mathbb{C}[\mathfrak{S}_i \times \mathfrak{S}_j \times \mathfrak{S}_k]$-modules. We will only prove (13.114.1), since (13.114.2) is analogous.

It is easy to see that every finite group G and every $\mathbb{C}G$-module P satisfy $\operatorname{Ind}_G^G P \cong P$. Applied to $G = \mathfrak{S}_k$ and $P = W$, this yields $\operatorname{Ind}_{\mathfrak{S}_k}^{\mathfrak{S}_k} W \cong W$.

Now, Exercise 4.1.2 (applied to $\mathfrak{S}_{i+j+k}$, $\mathfrak{S}_{i+j} \times \mathfrak{S}_k$, $\mathfrak{S}_i \times \mathfrak{S}_j \times \mathfrak{S}_k$ and $U \otimes V \otimes W$ instead of G, H, I and U) yields

$$\operatorname{Ind}_{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}} \left(\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j}\times\mathfrak{S}_k} (U \otimes V \otimes W) \right) \cong \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}} (U \otimes V \otimes W) .$$

Hence,

$$\begin{aligned}
\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}\left(U\otimes V\otimes W\right) &\cong \operatorname{Ind}_{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}\left(\underbrace{\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}\left(U\otimes V\otimes W\right)}_{\substack{\cong\left(\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j}^{\mathfrak{S}_{i+j}}(U\otimes V)\right)\otimes\left(\operatorname{Ind}_{\mathfrak{S}_k}^{\mathfrak{S}_k}W\right)\\ \text{(by (4.1.6), applied to } G_1=\mathfrak{S}_{i+j},\ G_2=\mathfrak{S}_k,\\ H_1=\mathfrak{S}_i\times\mathfrak{S}_j,\ H_2=\mathfrak{S}_k,\ U_1=U\otimes V \text{ and } U_2=W)}}\right)\\
&\cong \operatorname{Ind}_{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}\left(\left(\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j}^{\mathfrak{S}_{i+j}}\left(U\otimes V\right)\right)\otimes\underbrace{\left(\operatorname{Ind}_{\mathfrak{S}_k}^{\mathfrak{S}_k}W\right)}_{\cong W}\right)\\
&\cong \operatorname{Ind}_{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}\left(\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j}^{\mathfrak{S}_{i+j}}\left(U\otimes V\right)\otimes W\right).
\end{aligned}$$

This proves (13.114.1). Thus, the solution of Exercise 4.2.3 is complete.

13.115. **Solution to Exercise 4.3.9.** *Solution to Exercise 4.3.9.* (a) Let $n\in\mathbb{N}$. Let B denote the subgroup of $GL_n(\mathbb{F})$ consisting of all upper-triangular matrices. Then, $GL_n(\mathbb{F})=\bigsqcup_{w\in\mathfrak{S}_n}BwB$. (Indeed, this can be proven in the same way as we have shown the equality $GL_n=\bigsqcup_{w\in\mathfrak{S}_n}BwB$ in our above proof of Proposition 4.3.7(c), with the only difference that we are now working over $\mathbb{F}$ instead of $\mathbb{F}_q$.)

Let w_0 denote the permutation in $\mathfrak{S}_n$ which sends every $i\in\{1,2,\ldots,n\}$ to $n+1-i$; then, $w_0^2=\operatorname{id}$. (The permutation w_0 is written as $(n,n-1,\ldots,1)$ in one-line notation.)

Let $A\in GL_n(\mathbb{F})$. We have $w_0A\in GL_n(\mathbb{F})=\bigsqcup_{w\in\mathfrak{S}_n}BwB$. Thus, there exists some $w\in\mathfrak{S}_n$ such that $w_0A\in BwB$. Consider this w. There exist two upper-triangular invertible matrices L' and U such that $w_0A=L'wU$ (since $w_0A\in BwB$). Consider these L' and U. The matrix $w_0L'w_0$ is lower-triangular (since L' is upper-triangular, and since w_0 is what it is). Set $L=w_0L'w_0$. Then, $\underbrace{L}_{=w_0L'w_0}w_0wU=w_0L'\underbrace{w_0w_0}_{=w_0^2=\operatorname{id}}wU=w_0\underbrace{L'wU}_{=w_0A}=\underbrace{w_0w_0}_{=w_0^2=\operatorname{id}}A=A$. In other words, $LPU=A$ with $P=w_0w$. Since P is clearly a permutation matrix (being the product of the permutation matrices w_0 and w), we thus have shown that $A=LPU$ for a lower-triangular matrix $L\in GL_n(\mathbb{F})$, an upper-triangular matrix $U\in GL_n(\mathbb{F})$ and a permutation matrix $P\in\mathfrak{S}_n\subset GL_n(\mathbb{F})$. This solves Exercise 4.3.9(a).

(b) In the proof that follows, we shall essentially mimic the arguments used to prove $GL_n=\bigsqcup_{w\in\mathfrak{S}_n}BwB$ in our proof of Proposition 4.3.7(c) (but we will add some details in a few places).

We recall that B_n is a subgroup of $GL_n(\mathbb{F})$. Hence, every element of B_n is invertible in B_n. Likewise, every element of B_m is invertible in B_m.

Let us first show that the disjoint union $\bigsqcup_{f\in F_{n,m}}B_nfB_m$ is well-defined. This means proving that the sets B_nfB_m for $f\in F_{n,m}$ are disjoint.

For every $A\in\mathbb{F}^{n\times m}$, every $i\in\{1,2,\ldots,n+1\}$ and every $j\in\{0,1,\ldots,m\}$, let $r_{i,j}(A)$ denote the rank of the matrix obtained by restricting A to the rows $i,i+1,\ldots,n$ and columns $1,2,\ldots,j$. This rank $r_{i,j}(A)$ does not change when we replace A by XA for some $X\in B_n$ (because replacing A by XA for some $X\in B_n$ means that we add to each row of A a linear combination of the rows further below; but this row transformation does not change $r_{i,j}(A)$); neither does it change when we replace A by AY for some $Y\in B_m$ (for a similar reason). Hence, for every $f\in F_{n,m}$, $X\in B_n$, $Y\in B_m$, $i\in\{1,2,\ldots,n+1\}$ and $j\in\{0,1,\ldots,m\}$, we have

$$r_{i,j}(f)=r_{i,j}(Xf)=r_{i,j}(XfY). \tag{13.115.1}$$

Now, we claim that if $f\in F_{n,m}$ and $A\in B_nfB_m$, then we can reconstruct f from A. Indeed, let $f\in F_{n,m}$ and $A\in B_nfB_m$. Then, there exist $X\in B_n$ and $Y\in B_m$ such that $A=XfY$ (since $A\in B_nfB_m$). Consider these X and Y. Then, (13.115.1) yields $r_{i,j}(f) = r_{i,j}\left(\underbrace{XfY}_{=A}\right) = r_{i,j}(A)$ for every $i \in \{1, 2, \ldots, n+1\}$ and $j \in \{0, 1, \ldots, m\}$. Thus, from A we can reconstruct the ranks $r_{i,j}(f)$ for all $i \in \{1, 2, \ldots, n+1\}$ and $j \in \{0, 1, \ldots, m\}$.

Notice that $f \in F_{n,m}$. Thus, f is a matrix in $\{0,1\}^{n\times m}$ such that each row of f contains at most one 1 and each column of f contains at most one 1.

Now, fix $i \in \{1, 2, \ldots, n\}$ and $j \in \{1, 2, \ldots, m\}$. Let $f_{i,j}$ be the entry of f in row i and column j. We will now show that

$$f_{i,j} = r_{i,j}(f) - r_{i,j-1}(f) - r_{i+1,j}(f) + r_{i+1,j-1}(f). \tag{13.115.2}$$

Proof of (13.115.2). First of all, if the first j entries of the i-th row of f are all 0, then (13.115.2) holds for obvious reasons (in fact, in this case, it is clear that $f_{i,j} = 0$, $r_{i,j}(f) = r_{i+1,j}(f)$ and $r_{i,j-1}(f) = r_{i+1,j-1}(f)$). We thus WLOG assume that the first j entries of the i-th row of f are not all 0. Then, there must be a 1 among these entries. It must lie in a different column than the 1's appearing in all other rows of f (because each column of f contains at most one 1). Therefore, the first row of the matrix obtained by restricting f to the rows $i, i+1, \ldots, n$ and columns $1, 2, \ldots, j$ is linearly independent from its other rows. Thus,

$$r_{i,j}(f) = r_{i+1,j}(f) + 1.$$

If $f_{i,j} = 0$, then the same argument yields $r_{i,j-1}(f) = r_{i+1,j-1}(f) + 1$ (because if $f_{i,j} = 0$, then the 1 among the first j entries of the i-th row of f must not be the last of these entries, and so it is one of the first $j-1$ entries of the i-th row of f). On the other hand, if $f_{i,j} = 1$, then we have $r_{i,j-1}(f) = r_{i+1,j-1}(f)$ (because if $f_{i,j} = 1$, then the first $j-1$ entries of the i-th row of f must be all 0 (since the j-th entry of this row is a 1, but each row of f contains at most one 1)). We can subsume both of these statements in one equation, which holds both if $f_{i,j} = 0$ and if $f_{i,j} = 1$: namely, we have

$$r_{i,j-1}(f) = \begin{cases} r_{i+1,j-1}(f) + 1 & \text{if } f_{i,j} = 0; \\ r_{i+1,j-1}(f) & \text{if } f_{i,j} = 1 \end{cases} = r_{i+1,j-1}(f) + (1 - f_{i,j}).$$

Subtracting this equality from $r_{i,j}(f) = r_{i+1,j}(f) + 1$, we obtain

$$r_{i,j}(f) - r_{i,j-1}(f) = (r_{i+1,j}(f) + 1) - (r_{i+1,j-1}(f) + (1 - f_{i,j})) = r_{i+1,j}(f) - r_{i+1,j-1}(f) + f_{i,j}.$$

This is easily seen to be equivalent to (13.115.2). Thus, (13.115.2) is proven.

Now, we can reconstruct the ranks $r_{i,j}(f)$, $r_{i,j-1}(f)$, $r_{i+1,j}(f)$ and $r_{i+1,j-1}(f)$ from A (since from A we can reconstruct the ranks $r_{i,j}(f)$ for all $i \in \{1, 2, \ldots, n+1\}$ and $j \in \{0, 1, \ldots, m\}$). Hence, we can reconstruct $f_{i,j}$ from A (due to (13.115.2)).

Let us now forget that we fixed i and j. We thus have seen that we can reconstruct $f_{i,j}$ from A for every $i \in \{1, 2, \ldots, n\}$ and $j \in \{1, 2, \ldots, m\}$. In other words, we can reconstruct f from A.

Thus we have proven that if $f \in F_{n,m}$ and $A \in B_n f B_m$, then we can reconstruct f from A. In other words, the sets $B_n f B_m$ for $f \in F_{n,m}$ are disjoint. Thus, the disjoint union $\bigsqcup_{f\in F_{n,m}} B_n f B_m$ is well-defined.

It remains to prove that this disjoint union $\bigsqcup_{f\in F_{n,m}} B_n f B_m$ is $\mathbb{F}^{n\times m}$. In order to do so, it is clearly enough to show that every $g \in \mathbb{F}^{n\times m}$ belongs to $\bigsqcup_{f\in F_{n,m}} B_n f B_m$.

Let $g \in \mathbb{F}^{n\times m}$. We need to show that $g \in \bigsqcup_{f\in F_{n,m}} B_n f B_m$. In other words, we need to find some $f \in F_{n,m}$ such that $g \in B_n f B_m$. In order to do so, we shall find a matrix $f \in F_{n,m}$ which lies in $B_n g B_m$. Once this is done, it will follow that $g \in B_n f B_m$ (since every element of B_n is invertible in B_n, and every element of B_m is invertible in B_m), and we will be done.

We refer to gB_m and $B_n g$ as cosets, despite the fact that they are not subsets of a group.

The freedom to alter g within the coset gB_m allows one to scale columns and add scalar multiples of earlier columns to later columns. We claim that using such column operations, one can always find a representative g' for coset gB_m in which

- the bottommost nonzero entry of each nonzero column is 1 (call this entry a *pivot*),
- the entries to right of each pivot within its row are all 0, and
- there is at most one pivot in each row and at most one pivot in each column (so that their positions are the positions of the 1's in some matrix $f \in F_{n,m}$).

In fact, we will see below that $B_n g B_m = B_n f B_m$ in this case. The algorithm which produces g' from g is simple: starting with the leftmost nonzero column, find its bottommost nonzero entry, and scale the column to make this entry a 1, creating the pivot in this column. Now use this pivot to clear out all entries in its row to its right, using column operations that subtract multiples of this column from later columns. Having done this, move on to the next nonzero column to the right, and repeat, scaling to create a pivot, and using it to eliminate entries to its right.[862]

Having found this g' in gB_m, a similar algorithm using left multiplication by B_n shows that f lies in $B_n g' \subset B_n g' B_m = B_n g B_m$. This time no scalings are required to create the pivot entries: starting with the bottommost nonzero row, one uses its pivot to eliminate all the entries above it in the same column by adding multiples of this row to higher rows. Then do the same using the pivot in the next-to-bottom nonzero row, etc.[863] The result is the matrix f.

13.116. **Solution to Exercise 4.3.11.** *Solution to Exercise 4.3.11.* (a) Let us begin this solution by stating some trivialities. It is easy to see that every finite group G and every $\mathbb{C}G$-module P satisfy

$$\operatorname{Ind}_G^G P \cong P \tag{13.116.1}$$

and

$$\operatorname{Infl}_G^G P \cong P. \tag{13.116.2}$$

[862] To see that this works, we need to check three facts:

- **(a)** We will find a nonzero entry in every nonzero column during our algorithm.
- **(b)** Our column operations preserve the zeroes lying to the right of already existing pivots.
- **(c)** Every row contains at most one pivot at the end of the algorithm.

But fact **(a)** is a tautology. Fact **(b)** holds because all our operations either scale columns (which clearly preserves zero entries) or subtract a multiple of the column c containing the current pivot from a later column d (which will preserve every zero lying to the right of an already existing pivot, because any already existing pivot must lie in a column $b < c$ and therefore both columns c and d have zeroes in its row). Fact **(c)** follows from noticing that the entries to the right of a pivot in its row are 0.

[863] One thing that requires verification is the fact that these row operations preserve the following three properties of g':

- the bottommost nonzero entry of each nonzero column is 1 (call this entry a *pivot*),
- the entries to right of each pivot within its row are all 0, and
- there is at most one pivot in each row and at most one pivot in each column (so that their positions are the positions of the 1's in some matrix $f \in F_{n,m}$).

Let us show this, and also show that the positions of the pivots are preserved. Indeed, it is clear that the positions of the pivots are preserved (because zero columns stay zero, nonzero columns stay nonzero, and the bottommost entries of nonzero columns do not move); therefore it is enough to prove the following fact:

- **(d)** Consider an *elimination step*, by which we mean a step in which a pivot in some position a is used to eliminate all the entries above it in the same column. Assume that, before the elimination step, the entries to the right of a within its row were all 0. Let b be the position of another pivot that existed before this elimination step. Assume that, before the elimination step, the pivot at b equalled 1, and the entries to the right of b within its row were all 0. Then, after the elimination step, b is still a position of a pivot and this pivot still equals 1, and the entries to the right of b within its row are still 0.

So let us prove fact **(d)**. We prove it by contradiction: Assume that it is not the case. Then, the elimination step must have changed at least one of the entries weakly to the right of b within its row (because we already know that b is still a position of a pivot after the elimination step). In particular, the elimination step must have changed at least one entry in the row of b. Thus, b must lie in a row strictly above a (since otherwise, the elimination step would have not changed any entry in the row of b). Let c be the position in the same row as b and in the same column as a. Then, the entry at c before the elimination step must not have been 0 (since otherwise, the elimination step would not have changed any entry in the row of b). As a consequence, c must not lie to the right of b within its row (because before the elimination step, the entries to the right of b within its row were all 0). Thus, c lies weakly to the left of b within its row. In other words, the column containing b lies weakly right of the column containing c. In other words, the column containing b lies weakly right of the column containing a (since the column containing c is the column containing a). Hence, the column containing b must lie **strictly** right of the column containing a (since otherwise, a and b would lie in the same column, which is absurd because a and b are two distinct pivots). But let us recall that, before the elimination step, the entries to the right of a within its row were all 0. Let us call these entries the *silent entries*. Now, what did the elimination step do to the entries weakly to the right of b within its row? It changed them by adding multiples of the corresponding entries of the row containing a. But all these corresponding entries were silent entries (because the column containing b lies strictly right of the column containing a) and thus were 0. Hence, the elimination step did not change the entries weakly to the right of b within its row. This contradicts the fact that the elimination step must have changed at least one of the entries weakly to the right of b within its row. This contradiction finishes the proof of fact **(d)**.

Furthermore, if $\mathcal{G}_1$ and $\mathcal{G}_2$ be two groups, if $\mathcal{K}_1 \triangleleft \mathcal{G}_1$ and $\mathcal{K}_2 \triangleleft \mathcal{G}_2$ are normal subgroups, if $\mathcal{U}_1$ is a $\mathbb{C}[\mathcal{G}_1/\mathcal{K}_1]$-module, and if $\mathcal{U}_2$ is a $\mathbb{C}[\mathcal{G}_2/\mathcal{K}_2]$-module, then

$$\operatorname{Infl}_{(\mathcal{G}_1/\mathcal{K}_1)\times(\mathcal{G}_2/\mathcal{K}_2)}^{\mathcal{G}_1\times\mathcal{G}_2} (\mathcal{U}_1 \otimes \mathcal{U}_2) \cong \left(\operatorname{Infl}_{\mathcal{G}_1/\mathcal{K}_1}^{\mathcal{G}_1} \mathcal{U}_1\right) \otimes \left(\operatorname{Infl}_{\mathcal{G}_2/\mathcal{K}_2}^{\mathcal{G}_2} \mathcal{U}_2\right) \tag{13.116.3}$$

as $\mathbb{C}[\mathcal{G}_1 \times \mathcal{G}_2]$-modules. (This is an analogue of (4.1.6), but is trivial to prove.) Also, if $\mathcal{G}$, $\mathcal{H}$ and $\mathcal{I}$ are three groups such that $\mathcal{I} < \mathcal{H} < \mathcal{G}$, and if $\mathcal{U}$ is a $\mathbb{C}\mathcal{I}$-module, then

$$\operatorname{Infl}_{\mathcal{H}}^{\mathcal{G}} \operatorname{Infl}_{\mathcal{I}}^{\mathcal{H}} \mathcal{U} = \operatorname{Infl}_{\mathcal{I}}^{\mathcal{G}} \mathcal{U}. \tag{13.116.4}$$

(This is an analogue of Exercise 4.1.2, and is again trivial[864].)

Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ be an almost-composition of an $n \in \mathbb{N}$ satisfying $\ell \geq 1$. Let V_i be a $\mathbb{C}G_i$-module for every $i \in \{1, 2, \ldots, \ell\}$. We need to prove the two isomorphisms

$$\begin{aligned} &\operatorname{ind}_{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1},\alpha_\ell}^{n} \left(\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1}} (V_1 \otimes V_2 \otimes \cdots \otimes V_{\ell-1}) \otimes V_\ell\right) \\ &\cong \operatorname{ind}_{\alpha}^{n} (V_1 \otimes V_2 \otimes \cdots \otimes V_\ell) \end{aligned} \tag{13.116.5}$$

and

$$\begin{aligned} &\operatorname{ind}_{\alpha_1,\alpha_2+\alpha_3+\cdots+\alpha_\ell}^{n} \left(V_1 \otimes \operatorname{ind}_{(\alpha_2,\alpha_3,\ldots,\alpha_\ell)}^{\alpha_2+\alpha_3+\cdots+\alpha_\ell} (V_2 \otimes V_3 \otimes \cdots \otimes V_\ell)\right) \\ &\cong \operatorname{ind}_{\alpha}^{n} (V_1 \otimes V_2 \otimes \cdots \otimes V_\ell). \end{aligned} \tag{13.116.6}$$

We will only prove (13.116.5), since the proof of (13.116.6) is analogous.

Let m be the nonnegative integer $\alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1}$. Then, $(\alpha_1, \alpha_2, \ldots, \alpha_{\ell-1})$ is an almost-composition of m, and we have $\alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1} = m$.

Let W denote the $\mathbb{C}[G_1 \times G_2 \times \cdots \times G_{\ell-1}]$-module $V_1 \otimes V_2 \otimes \cdots \otimes V_{\ell-1}$. Then, $V_1 \otimes V_2 \otimes \cdots \otimes V_{\ell-1} = W$ and $V_1 \otimes V_2 \otimes \cdots \otimes V_\ell = \underbrace{(V_1 \otimes V_2 \otimes \cdots \otimes V_{\ell-1})}_{=W} \otimes V_\ell = W \otimes V_\ell$ and $\alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1} = m$. Hence, the relation (13.116.5) (which we want to prove) rewrites as

$$\operatorname{ind}_{m,\alpha_\ell}^{n} \left(\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^{m} W \otimes V_\ell\right) \cong \operatorname{ind}_{\alpha}^{n} (W \otimes V_\ell). \tag{13.116.7}$$

It thus remains to prove (13.116.7).

We distinguish between two cases:

Case 1: We have $G_* = \mathfrak{S}_*$ or $G_* = \mathfrak{S}_*[\Gamma]$.

Case 2: We have $G_* = GL_*$.

Let us consider Case 1 first. In this case, we have $G_* = \mathfrak{S}_*$ or $G_* = \mathfrak{S}_*[\Gamma]$. Thus, $\operatorname{ind}_{\beta}^{N} = \operatorname{Ind}_{G_\beta}^{G_N}$ for every $N \in \mathbb{N}$ and every almost-composition β of N (by the definition of $\operatorname{ind}_{\beta}^{N}$), and $\operatorname{ind}_{i,j}^{N} = \operatorname{Ind}_{G_i \times G_j}^{G_N}$ for every $N \in \mathbb{N}$ and every $i, j \in \mathbb{N}$ satisfying $i + j = N$ (by the definition of $\operatorname{ind}_{i,j}^{N}$).

[864] Note that the equality sign in (13.116.4) is a honest equality, not just a canonical isomorphism.

Since $\operatorname{ind}_\beta^N = \operatorname{Ind}_{G_\beta}^{G_N}$ for every $N \in \mathbb{N}$ and every almost-composition β of N, we have $\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^m = \operatorname{Ind}_{G_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}^{G_m}$. Thus,

$$\begin{aligned}
&\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^m W \otimes V_\ell \\
&= \underbrace{\operatorname{Ind}_{G_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}^{G_m} W}_{\substack{=\operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}}^{G_m} W \\ (\text{since } G_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}=G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}})}} \otimes \underbrace{V_\ell}_{\substack{\cong\operatorname{Ind}_{G_{\alpha_\ell}}^{G_{\alpha_\ell}} V_\ell \\ (\text{because (13.116.1) (applied} \\ \text{to } G=G_{\alpha_\ell} \text{ and } P=V_\ell) \text{ yields } \operatorname{Ind}_{G_{\alpha_\ell}}^{G_{\alpha_\ell}} V_\ell\cong V_\ell)}} \\
&\cong \left(\operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}}^{G_m} W\right) \otimes \left(\operatorname{Ind}_{G_{\alpha_\ell}}^{G_{\alpha_\ell}} V_\ell\right) \cong \operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}\times G_{\alpha_\ell}}^{G_m\times G_{\alpha_\ell}} (W\otimes V_\ell) \\
&\qquad \left(\begin{array}{c} \text{since Exercise 4.1.3 (applied to } G_m,\ G_{\alpha_\ell},\ G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}},\ G_{\alpha_\ell}, \\ W \text{ and } V_\ell \text{ instead of } G_1,\ G_2,\ H_1,\ H_2,\ U_1 \text{ and } U_2\text{) yields} \\ \operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}\times G_{\alpha_\ell}}^{G_{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1}}\times G_{\alpha_\ell}} (W\otimes V_\ell) \\ \cong \left(\operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}}^{G_{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1}}} W\right)\otimes\left(\operatorname{Ind}_{G_{\alpha_\ell}}^{G_{\alpha_\ell}} V_\ell\right) \end{array}\right) \\
&= \operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_\ell}}^{G_m\times G_{\alpha_\ell}} (W\otimes V_\ell). \qquad (13.116.8)
\end{aligned}$$

But from $m = \alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1}$, we obtain $m + \alpha_\ell = (\alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1}) + \alpha_\ell = \alpha_1 + \alpha_2 + \cdots + \alpha_\ell = n$ (since $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ is an almost-composition of n). Thus, since $\operatorname{ind}_{i,j}^N = \operatorname{Ind}_{G_i\times G_j}^{G_N}$ for every $N \in \mathbb{N}$ and every $i, j \in \mathbb{N}$ satisfying $i + j = N$, we have $\operatorname{ind}_{m,\alpha_\ell}^n = \operatorname{Ind}_{G_m\times G_{\alpha_\ell}}^{G_n}$. Thus,

$$\begin{aligned}
&\operatorname{ind}_{m,\alpha_\ell}^n \left(\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^m W\otimes V_\ell\right) \\
&= \operatorname{Ind}_{G_m\times G_{\alpha_\ell}}^{G_n} \left(\underbrace{\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^m W\otimes V_\ell}_{\substack{\cong\operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_\ell}}^{G_m\times G_{\alpha_\ell}} (W\otimes V_\ell) \\ (\text{by (13.116.8)})}}\right) \cong \operatorname{Ind}_{G_m\times G_{\alpha_\ell}}^{G_n} \operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_\ell}}^{G_m\times G_{\alpha_\ell}} (W\otimes V_\ell) \\
&\cong \operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_\ell}}^{G_n} (W\otimes V_\ell) \qquad \left(\begin{array}{c} \text{by Exercise 4.1.2, applied to } G=G_n,\ H=G_m\times G_{\alpha_\ell}, \\ I=G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_\ell} \text{ and } U=W\otimes V_\ell \end{array}\right) \\
&= \operatorname{ind}_\alpha^n (W\otimes V_\ell) \qquad \left(\text{since } \operatorname{Ind}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_\ell}}^{G_n} = \operatorname{ind}_\alpha^n \text{ (by the definition of } \operatorname{ind}_\alpha^n)\right).
\end{aligned}$$

This proves (13.116.5). Hence, (13.116.5) is proven in Case 1.

Let us now consider Case 2. In this case, we have $G_* = GL_*$. Hence, $\operatorname{ind}_\beta^N = \operatorname{Ind}_{P_\beta}^{G_N} \operatorname{Infl}_{G_\beta}^{P_\beta}$ for every $N \in \mathbb{N}$ and every almost-composition β of N (by the definition of $\operatorname{ind}_\beta^N$), and $\operatorname{ind}_{i,j}^N = \operatorname{Ind}_{P_{i,j}}^{G_N} \operatorname{Infl}_{G_i\times G_j}^{P_{i,j}}$ for every $N \in \mathbb{N}$ and every $i, j \in \mathbb{N}$ satisfying $i + j = N$ (by the definition of $\operatorname{ind}_{i,j}^N$).

Since $\operatorname{ind}_\beta^N = \operatorname{Ind}_{P_\beta}^{G_N} \operatorname{Infl}_{G_\beta}^{P_\beta}$ for every $N \in \mathbb{N}$ and every almost-composition β of N, we have

$$\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^m = \operatorname{Ind}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}^{G_m} \operatorname{Infl}_{G_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}} = \operatorname{Ind}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}^{G_m} \operatorname{Infl}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}$$

(since $G_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} = G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}}$). Therefore,

$$\begin{align*}
&\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} W \otimes V_\ell \\
&= \operatorname{Ind}^{G_m}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}} \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}} W \otimes \underbrace{V_\ell}_{\substack{\cong \operatorname{Ind}^{G_{\alpha_\ell}}_{G_{\alpha_\ell}} V_\ell \\ \text{(because (13.116.1) (applied} \\ \text{to } G=G_{\alpha_\ell} \text{ and } P=V_\ell\text{) yields } \operatorname{Ind}^{G_{\alpha_\ell}}_{G_{\alpha_\ell}} V_\ell \cong V_\ell\text{)}}} \\
&\cong \left(\operatorname{Ind}^{G_m}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}} \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}} W \right) \otimes \left(\operatorname{Ind}^{G_{\alpha_\ell}}_{G_{\alpha_\ell}} V_\ell \right) \\
&\cong \operatorname{Ind}^{G_m\times G_{\alpha_\ell}}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}} \left(\operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}} W \otimes \underbrace{V_\ell}_{\substack{\cong \operatorname{Infl}^{G_{\alpha_\ell}}_{G_{\alpha_\ell}} V_\ell \\ \text{(because (13.116.1) (applied} \\ \text{to } G=G_{\alpha_\ell} \text{ and } P=V_\ell\text{) yields } \operatorname{Infl}^{G_{\alpha_\ell}}_{G_{\alpha_\ell}} V_\ell \cong V_\ell\text{)}}} \right) \\
&\qquad \left(\begin{array}{c} \text{since Exercise 4.1.3 (applied to } G_m,\ G_{\alpha_\ell},\ P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})},\ G_{\alpha_\ell}, \\ \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}} W \text{ and } V_\ell \text{ instead of } G_1,\ G_2,\ H_1,\ H_2,\ U_1 \text{ and } U_2\text{) yields} \\ \operatorname{Ind}^{G_m\times G_{\alpha_\ell}}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}} \left(\operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}} W \otimes V_\ell \right) \\ = \left(\operatorname{Ind}^{G_m}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}} \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}} W \right) \otimes \left(\operatorname{Ind}^{G_{\alpha_\ell}}_{G_{\alpha_\ell}} V_\ell \right) \end{array} \right) \\
&\cong \operatorname{Ind}^{G_m\times G_{\alpha_\ell}}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}} \underbrace{\left(\operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}} W \otimes \operatorname{Infl}^{G_{\alpha_\ell}}_{G_{\alpha_\ell}} V_\ell \right)}_{\substack{\cong \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}\times G_{\alpha_\ell}} (W\otimes V_\ell) \\ \text{(by (13.116.3), applied to} \\ \mathcal{G}_1 = P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})},\ \mathcal{G}_2 = G_{\alpha_\ell},\ \mathcal{K}_1 = K_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}, \\ \mathcal{K}_2 = G_{\alpha_\ell},\ \mathcal{U}_1 = W \text{ and } \mathcal{U}_2 = V_\ell \\ \text{(because } K_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \text{ is a normal subgroup} \\ \text{of } P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \text{ and the quotient is} \\ P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}/K_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} = G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}\text{))}}} \\
&\cong \operatorname{Ind}^{G_m\times G_{\alpha_\ell}}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}} \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}\times G_{\alpha_\ell}} (W \otimes V_\ell) . \tag{13.116.9}
\end{align*}$$

But from $m = \alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1}$, we obtain $m + \alpha_\ell = (\alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1}) + \alpha_\ell = \alpha_1 + \alpha_2 + \cdots + \alpha_\ell = n$ (since $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ is an almost-composition of n). Thus, since $\operatorname{ind}^N_{i,j} = \operatorname{Ind}^{G_N}_{P_{i,j}} \operatorname{Infl}^{P_{i,j}}_{G_i\times G_j}$ for every $N \in \mathbb{N}$ and every $i, j \in \mathbb{N}$ satisfying $i + j = N$, we have $\operatorname{ind}^n_{m,\alpha_\ell} = \operatorname{Ind}^{G_n}_{P_{m,\alpha_\ell}} \operatorname{Infl}^{P_{m,\alpha_\ell}}_{G_m\times G_{\alpha_\ell}}$, so that

$$\begin{align*}
&\operatorname{ind}^n_{m,\alpha_\ell} \left(\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} W \otimes V_\ell \right) \\
&= \operatorname{Ind}^{G_n}_{P_{m,\alpha_\ell}} \operatorname{Infl}^{P_{m,\alpha_\ell}}_{G_m\times G_{\alpha_\ell}} \left(\underbrace{\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} W \otimes V_\ell}_{\substack{\cong \operatorname{Ind}^{G_m\times G_{\alpha_\ell}}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}} \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}\times G_{\alpha_\ell}} (W\otimes V_\ell) \\ \text{(by (13.116.9))}}} \right) \\
&\cong \operatorname{Ind}^{G_n}_{P_{m,\alpha_\ell}} \operatorname{Infl}^{P_{m,\alpha_\ell}}_{G_m\times G_{\alpha_\ell}} \operatorname{Ind}^{G_m\times G_{\alpha_\ell}}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}} \operatorname{Infl}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\times G_{\alpha_\ell}}_{G_{\alpha_1}\times G_{\alpha_2}\times\cdots\times G_{\alpha_{\ell-1}}\times G_{\alpha_\ell}} (W \otimes V_\ell) \tag{13.116.10}
\end{align*}$$

Now, we are going to prove that

$$\operatorname{Infl}_{G_m \times G_{\alpha_\ell}}^{P_{m,\alpha_\ell}} \operatorname{Ind}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}}^{G_m \times G_{\alpha_\ell}} Z \cong \operatorname{Ind}_{P_\alpha}^{P_{m,\alpha_\ell}} \operatorname{Infl}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}}^{P_\alpha} Z \tag{13.116.11}$$

for every $\mathbb{C}\left[P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}\right]$-module Z. In order to do so, we try to apply Exercise 4.1.11 to $G = P_{m,\alpha_\ell}$, $H = P_\alpha$, $K = K_{m,\alpha_\ell}$ and $V = Z$. This yields (13.116.11) if we can prove the following two statements:

(1) We have $K_{m,\alpha_\ell} < P_\alpha < P_{m,\alpha_\ell}$ and $K_{m,\alpha_\ell} \triangleleft P_{m,\alpha_\ell}$.
(2) The quotient $P_{m,\alpha_\ell}/K_{m,\alpha_\ell}$ is canonically identified with $G_m \times G_{\alpha_\ell}$ in such a way that its subgroup $P_\alpha/K_{m,\alpha_\ell}$ is canonically identified with $P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}$.

The first of these two statements is clear (using $m = \alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1}$ and $\alpha = (\alpha_1, \alpha_2, ..., \alpha_\ell)$). It remains to prove the second statement. We know how $P_{m,\alpha_\ell}/K_{m,\alpha_\ell}$ is identified with $G_m \times G_{\alpha_\ell}$ already. The thing that we need to prove is that the subgroup $P_\alpha/K_{m,\alpha_\ell}$ of $P_{m,\alpha_\ell}/K_{m,\alpha_\ell}$ is canonically identified with $P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}$. In other words, we need to prove that the projection of the subgroup P_α of P_{m,α_ℓ} onto $G_m \times G_{\alpha_\ell}$ is precisely $P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}$. But this is obvious. Hence, the second statement is proven, and so we are able to apply Exercise 4.1.11 and therefore obtain (13.116.11).

Now, (13.116.10) becomes

$$\begin{aligned}
&\operatorname{ind}_{m,\alpha_\ell}^{n}\left(\operatorname{ind}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}^{m} W \otimes V_\ell\right) \\
&\cong \operatorname{Ind}_{P_{m,\alpha_\ell}}^{G_n} \underbrace{\operatorname{Infl}_{G_m \times G_{\alpha_\ell}}^{P_{m,\alpha_\ell}} \operatorname{Ind}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}}^{G_m \times G_{\alpha_\ell}} \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}} (W \otimes V_\ell)}_{\substack{\cong \operatorname{Ind}_{P_\alpha}^{P_{m,\alpha_\ell}} \operatorname{Infl}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}}^{P_\alpha} \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}} (W \otimes V_\ell) \\ \text{(by (13.116.11), applied to } Z = \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}} (W \otimes V_\ell))}} \\
&\cong \operatorname{Ind}_{P_{m,\alpha_\ell}}^{G_n} \operatorname{Ind}_{P_\alpha}^{P_{m,\alpha_\ell}} \operatorname{Infl}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}}^{P_\alpha} \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}} (W \otimes V_\ell) \\
&\cong \operatorname{Ind}_{P_\alpha}^{G_n} \underbrace{\operatorname{Infl}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}}^{P_\alpha} \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}} (W \otimes V_\ell)}_{\substack{= \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_\alpha} (W \otimes V_\ell) \\ \text{(by (13.116.4), applied to } \mathcal{G} = P_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}, \\ \mathcal{H} = P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell},\ \mathcal{I} = G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell} \text{ and } \mathcal{U} = W \otimes V_\ell)}} \\
&\qquad \left(\begin{array}{c} \text{by Exercise 4.1.2, applied to } G = G_n,\ H = P_{m,\alpha_\ell}, \\ I = P_\alpha \text{ and } U = \operatorname{Infl}_{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}}^{P_\alpha} \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})} \times G_{\alpha_\ell}} (W \otimes V_\ell) \end{array}\right) \\
&= \operatorname{Ind}_{P_\alpha}^{G_n} \operatorname{Infl}_{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell}}^{P_\alpha} (W \otimes V_\ell) \\
&= \operatorname{Ind}_{P_\alpha}^{G_n} \operatorname{Infl}_{G_\alpha}^{P_\alpha} (W \otimes V_\ell) \qquad \left(\text{since } G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_{\ell-1}} \times G_{\alpha_\ell} = G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_\ell} = G_\alpha\right) \\
&= \operatorname{ind}_\alpha^n (W \otimes V_\ell) \qquad \left(\text{since } \operatorname{Ind}_{P_\alpha}^{G_n} \operatorname{Infl}_{G_\alpha}^{P_\alpha} = \operatorname{ind}_\alpha^n \text{ (by the definition of } \operatorname{ind}_\alpha^n\text{)}\right).
\end{aligned}$$

This proves (13.116.5). Hence, (13.116.5) is proven in Case 2.

Now, (13.116.5) is proven in both Cases 1 and 2. Hence, (13.116.5) always holds. This completes the solution to Exercise 4.3.11(a).

(b) *Alternative solution to Exercise 4.2.3:* Let G_* be the tower $\mathfrak{S}_*$ of groups. We can then apply Exercise 4.3.11(a) to $\ell = 3$, $n = i + j + k$, $\alpha = (i, j, k)$, $V_1 = U$, $V_2 = V$ and $V_3 = W$. As the result, we obtain

$$\begin{aligned}
\operatorname{ind}_{i+j,k}^{i+j+k}\left(\operatorname{ind}_{(i,j)}^{i+j} (U \otimes V) \otimes W\right) &\cong \operatorname{ind}_{(i,j,k)}^{i+j+k} (U \otimes V \otimes W) \\
&\cong \operatorname{ind}_{i,j+k}^{i+j+k}\left(U \otimes \operatorname{ind}_{(j,k)}^{j+k} (V \otimes W)\right).
\end{aligned}$$

Since $\operatorname{ind}_{i+j,k}^{i+j+k} = \operatorname{Ind}_{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}$, $\operatorname{ind}_{(i,j)}^{i+j} = \operatorname{ind}_{i,j}^{i+j} = \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j}^{\mathfrak{S}_{i+j}}$, $\operatorname{ind}_{(i,j,k)}^{i+j+k} = \operatorname{Ind}_{G_{i,j,k}}^{\mathfrak{S}_{i+j+k}} = \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}$ (because $G_{i,j,k} = \mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k$), $\operatorname{ind}_{i,j+k}^{i+j+k} = \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_{j+k}}^{\mathfrak{S}_{i+j+k}}$ and $\operatorname{ind}_{(j,k)}^{j+k} = \operatorname{ind}_{j,k}^{j+k} = \operatorname{Ind}_{\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{j+k}}$, this rewrites as follows:

$$\begin{aligned}\operatorname{Ind}_{\mathfrak{S}_{i+j}\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}\left(\operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j}^{\mathfrak{S}_{i+j}}(U\otimes V)\otimes W\right) &\cong \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{i+j+k}}(U\otimes V\otimes W)\\ &\cong \operatorname{Ind}_{\mathfrak{S}_i\times\mathfrak{S}_{j+k}}^{\mathfrak{S}_{i+j+k}}\left(U\otimes \operatorname{Ind}_{\mathfrak{S}_j\times\mathfrak{S}_k}^{\mathfrak{S}_{j+k}}(V\otimes W)\right).\end{aligned}$$

Thus, Exercise 4.2.3 is solved again. Hence, we have solved Exercise 4.3.11(b).

(c) Let $\Sigma = \bigsqcup_{n\geq 0}\operatorname{Irr}(G_n)$. We have to prove that the map m is associative. In other words, we have to prove that $m(m(\alpha\otimes\beta)\otimes\gamma) = m(\alpha\otimes m(\beta\otimes\gamma))$ for any three elements α, β and γ of A. In order to do so, it is clearly enough to show that $m(m(\alpha\otimes\beta)\otimes\gamma) = m(\alpha\otimes m(\beta\otimes\gamma))$ for any three elements α, β and γ of Σ (because Σ is a $\mathbb{Z}$-module basis of A, and the equality $m(m(\alpha\otimes\beta)\otimes\gamma) = m(\alpha\otimes m(\beta\otimes\gamma))$ is $\mathbb{Z}$-linear in each of α, β and γ). So let α, β and γ be three elements of Σ. Then, there exists $i\in\mathbb{N}$, $j\in\mathbb{N}$ and $k\in\mathbb{N}$ satisfying $\alpha\in\operatorname{Irr}(G_i)$, $\beta\in\operatorname{Irr}(G_j)$ and $\gamma\in\operatorname{Irr}(G_k)$ (since α, β and γ belong to $\Sigma = \bigsqcup_{n\geq 0}\operatorname{Irr}(G_n)$). Consider these i, j and k.

There exists an irreducible $\mathbb{C}G_i$-module U satisfying $\alpha = \chi_U$ (since $\alpha\in\operatorname{Irr}(G_i)$). Similarly, there exists an irreducible $\mathbb{C}G_j$-module V satisfying $\beta = \chi_V$, and an irreducible $\mathbb{C}G_k$-module W satisfying $\gamma = \chi_W$. Consider these U, V and W.

We can apply Exercise 4.3.11(a) to $\ell = 3$, $n = i+j+k$, $\alpha = (i,j,k)$, $V_1 = U$, $V_2 = V$ and $V_3 = W$. As the result, we obtain

$$\begin{aligned}\operatorname{ind}_{i+j,k}^{i+j+k}\left(\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)\otimes W\right) &\cong \operatorname{ind}_{(i,j,k)}^{i+j+k}(U\otimes V\otimes W)\\ &\cong \operatorname{ind}_{i,j+k}^{i+j+k}\left(U\otimes\operatorname{ind}_{(j,k)}^{j+k}(V\otimes W)\right).\end{aligned}$$

Thus,

$$\operatorname{ind}_{i+j,k}^{i+j+k}\left(\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)\otimes W\right) \cong \operatorname{ind}_{i,j+k}^{i+j+k}\left(U\otimes\operatorname{ind}_{(j,k)}^{j+k}(V\otimes W)\right).$$

Since isomorphic representations have equal characters, this yields

$$\chi_{\operatorname{ind}_{i+j,k}^{i+j+k}\left(\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)\otimes W\right)} = \chi_{\operatorname{ind}_{i,j+k}^{i+j+k}\left(U\otimes\operatorname{ind}_{(j,k)}^{j+k}(V\otimes W)\right)}. \tag{13.116.12}$$

Since $\alpha = \chi_U$ and $\beta = \chi_V$, we have

$$\begin{aligned} m(\alpha\otimes\beta) &= m(\chi_U\otimes\chi_V) = \operatorname{ind}_{i,j}^{i+j}(\chi_U\otimes\chi_V) && (\text{since } U \text{ is a } \mathbb{C}G_i\text{-module and } V \text{ is a } \mathbb{C}G_j\text{-module})\\ &= \chi_{\operatorname{ind}_{i,j}^{i+j}(U\otimes V)} = \chi_{\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)} && \left(\text{since } \operatorname{ind}_{i,j}^{i+j} = \operatorname{ind}_{(i,j)}^{i+j}\right).\end{aligned}$$

Thus,

$$\begin{aligned} m\left(\underbrace{m(\alpha\otimes\beta)}_{=\chi_{\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)}} \otimes \underbrace{\gamma}_{=\chi_W}\right) &\\ = m\left(\chi_{\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)}\otimes\chi_W\right) &= \operatorname{ind}_{i+j,k}^{i+j+k}\left(\chi_{\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)}\otimes\chi_W\right)\\ &\qquad\left(\text{since } \operatorname{ind}_{(i,j)}^{i+j}(U\otimes V) \text{ is a } \mathbb{C}[G_{i+j}]\text{-module and } W \text{ is a } \mathbb{C}G_k\text{-module}\right)\\ = \chi_{\operatorname{ind}_{i+j,k}^{i+j+k}\left(\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)\otimes W\right)}. & \qquad (13.116.13)\end{aligned}$$

Similarly,

$$m(\alpha\otimes m(\beta\otimes\gamma)) = \chi_{\operatorname{ind}_{i,j+k}^{i+j+k}\left(U\otimes\operatorname{ind}_{(j,k)}^{j+k}(V\otimes W)\right)}. \tag{13.116.14}$$

Now, (13.116.13) becomes

$$\begin{aligned} m(m(\alpha\otimes\beta)\otimes\gamma) &= \chi_{\operatorname{ind}_{i+j,k}^{i+j+k}\left(\operatorname{ind}_{(i,j)}^{i+j}(U\otimes V)\otimes W\right)} = \chi_{\operatorname{ind}_{i,j+k}^{i+j+k}\left(U\otimes\operatorname{ind}_{(j,k)}^{j+k}(V\otimes W)\right)} && (\text{by } (13.116.12))\\ &= m(\alpha\otimes m(\beta\otimes\gamma)) && (\text{by } (13.116.14)).\end{aligned}$$

This is what we wanted to prove. Thus, Exercise 4.3.11(c) is solved.

(d) Let $\Sigma = \bigsqcup_{n\geq 0} \operatorname{Irr}(G_n)$.

We will solve Exercise 4.3.11(d) by induction over ℓ. The induction base (the case $\ell = 0$) is trivial, so we come to the induction step. Fix a positive integer ℓ. We assume that Exercise 4.3.11(d) is already solved for $\ell - 1$ instead of ℓ. We now need to solve Exercise 4.3.11(d) for our ℓ.

Let $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ be an almost-composition of an $n \in \mathbb{N}$. Let $\chi_i \in R(G_{\alpha_i})$ for every $i \in \{1, 2, \ldots, \ell\}$. We will show that

$$\chi_1\chi_2\cdots\chi_\ell = \operatorname{ind}^n_\alpha (\chi_1 \otimes \chi_2 \otimes \cdots \otimes \chi_\ell).$$

Since this equality is $\mathbb{Z}$-linear in each of χ_1, χ_2, ..., χ_ℓ, we can WLOG assume that χ_1, χ_2, ..., χ_ℓ all lie in Σ (since Σ is a basis of A). Assume this. Then, $\chi_i \in \Sigma \cap R(G_{\alpha_i}) = \operatorname{Irr}(G_{\alpha_i})$ for every $i \in \{1, 2, ..., \ell\}$. Hence, for every $i \in \{1, 2, ..., \ell\}$, there exists an irreducible $\mathbb{C}G_{\alpha_i}$-module V_i such that $\chi_i = \chi_{V_i}$. Consider this V_i.

Let $m = \alpha_1 + \alpha_2 + \cdots + \alpha_{\ell-1}$. By the induction hypothesis, we can apply Exercise 4.3.11(d) to the almost-composition $(\alpha_1, \alpha_2, ..., \alpha_{\ell-1})$ of m. As a result, we obtain

$$\begin{aligned}
\chi_1\chi_2\cdots\chi_{\ell-1} &= \operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\left(\underbrace{\chi_1}_{=\chi_{V_1}} \otimes \underbrace{\chi_2}_{=\chi_{V_2}} \otimes \cdots \otimes \underbrace{\chi_{\ell-1}}_{=\chi_{V_{\ell-1}}}\right)\\
&= \operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\underbrace{\left(\chi_{V_1} \otimes \chi_{V_2} \otimes \cdots \otimes \chi_{V_{\ell-1}}\right)}_{=\chi_{V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1}}} = \operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}\left(\chi_{V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1}}\right)\\
&= \chi_{\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1})}.
\end{aligned}$$

Now,

$$\begin{aligned}
\chi_1\chi_2\cdots\chi_\ell &= \underbrace{(\chi_1\chi_2\cdots\chi_{\ell-1})}_{=\chi_{\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1})}} \underbrace{\chi_\ell}_{=\chi_{V_\ell}}\\
&= \chi_{\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1})}\chi_{V_\ell} = \operatorname{ind}^n_{m,\alpha_\ell}\left(\chi_{\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1})} \otimes \chi_{V_\ell}\right)\\
&\qquad \left(\begin{array}{c}\text{since } \operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1}) \text{ is a } \mathbb{C}G_m\text{-module, and}\\ V_\ell \text{ is a } \mathbb{C}G_{\alpha_\ell}\text{-module}\end{array}\right)\\
&= \chi_{\operatorname{ind}^n_{m,\alpha_\ell}\left(\operatorname{ind}^m_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1})\otimes V_\ell\right)}\\
&= \chi_{\operatorname{ind}^n_{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1},\alpha_\ell}\left(\operatorname{ind}^{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1}}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1})\otimes V_\ell\right)} \qquad (\text{since } m = \alpha_1+\alpha_2+\cdots+\alpha_{\ell-1})\\
&= \chi_{\operatorname{ind}^n_\alpha(V_1\otimes V_2\otimes\cdots\otimes V_\ell)}
\end{aligned}$$

(since Exercise 4.3.11(a) yields $\operatorname{ind}^n_{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1},\alpha_\ell}\left(\operatorname{ind}^{\alpha_1+\alpha_2+\cdots+\alpha_{\ell-1}}_{(\alpha_1,\alpha_2,\ldots,\alpha_{\ell-1})}(V_1\otimes V_2\otimes\cdots\otimes V_{\ell-1})\otimes V_\ell\right) \cong \operatorname{ind}^n_\alpha(V_1\otimes V_2\otimes\cdots\otimes V_\ell)$). Compared with

$$\operatorname{ind}^n_\alpha\left(\underbrace{\chi_1}_{=\chi_{V_1}} \otimes \underbrace{\chi_2}_{=\chi_{V_2}} \otimes \cdots \otimes \underbrace{\chi_\ell}_{=\chi_{V_\ell}}\right) = \operatorname{ind}^n_\alpha(\chi_{V_1}\otimes\chi_{V_2}\otimes\cdots\otimes\chi_{V_\ell}) = \chi_{\operatorname{ind}^n_\alpha(V_1\otimes V_2\otimes\cdots\otimes V_\ell)},$$

this yields $\chi_1\chi_2\cdots\chi_\ell = \operatorname{ind}^n_\alpha(\chi_1\otimes\chi_2\otimes\cdots\otimes\chi_\ell)$. Thus, Exercise 4.3.11(d) is solved for our ℓ. This completes the induction step, and so Exercise 4.3.11(d) is solved.

(e) Let $n \in \mathbb{N}$, $\ell \in \mathbb{N}$ and $\chi \in R(G_n)$. We need to prove that $\Delta^{(\ell-1)}\chi = \sum \operatorname{res}^n_\alpha \chi$. Since this equality is $\mathbb{Z}$-linear in χ, we can WLOG assume that $\chi \in \operatorname{Irr}(G_n)$ (since $\operatorname{Irr}(G_n)$ is a $\mathbb{Z}$-module basis of $R(G_n)$). Assume this. Then, $\chi = \chi_P$ for some irreducible $\mathbb{C}G_n$-module P. Consider this P.

Similarly to how we showed (4.2.1), we can prove that

$$\operatorname{Hom}_{\mathbb{C}G_n}(\operatorname{ind}^n_\alpha U, V) \cong \operatorname{Hom}_{\mathbb{C}G_\alpha}(U, \operatorname{res}^n_\alpha V) \tag{13.116.15}$$

for every almost-composition α of n, every $\mathbb{C}G_\alpha$-module U and every $\mathbb{C}G_n$-module V. Thus,

$$(\operatorname{ind}^n_\alpha \varphi, \psi)_{R(G_n)} = (\varphi, \operatorname{res}^n_\alpha \psi)_{R(G_\alpha)} \tag{13.116.16}$$

for every almost-composition α of n, every $\varphi \in R(G_\alpha)$ and every $\psi \in R(G_n)$ [865].

The bilinear form $(\cdot, \cdot)_A$ on A induces a bilinear form $(\cdot, \cdot)_{A^{\otimes \ell}}$ on $A^{\otimes \ell}$. It is easy to see that the maps $m^{(\ell-1)}$ and $\Delta^{(\ell-1)}$ are adjoint with respect to the forms $(\cdot, \cdot)_A$ and $(\cdot, \cdot)_{A^{\otimes \ell}}$. [866] Hence, any $\varphi \in A$ and $\rho \in A^{\otimes \ell}$ satisfy

$$\left(\Delta^{(\ell-1)}\varphi, \rho\right)_{A^{\otimes \ell}} = \left(\varphi, m^{(\ell-1)}\rho\right)_A . \tag{13.116.17}$$

Since $A = \bigoplus_{n \geq 0} R(G_n)$, we have

$$\begin{aligned}
A^{\otimes \ell} &= \left(\bigoplus_{n \geq 0} R(G_n)\right)^{\otimes \ell} = \bigoplus_{n_1, n_2, \ldots, n_\ell \geq 0} \underbrace{R(G_{n_1}) \otimes R(G_{n_2}) \otimes \cdots \otimes R(G_{n_\ell})}_{= R\left(G_{n_1} \times G_{n_2} \times \cdots \times G_{n_\ell}\right)} \\
&= \bigoplus_{n_1, n_2, \ldots, n_\ell \geq 0} R(G_{n_1} \times G_{n_2} \times \cdots \times G_{n_\ell}) \\
&= \bigoplus_{\substack{\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_\ell) \text{ is an} \\ \text{almost-composition of length } \ell}} R\left(\underbrace{G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_\ell}}_{= G_\alpha}\right) \\
&= \bigoplus_{\substack{\alpha \text{ is an almost-composition} \\ \text{of length } \ell}} R(G_\alpha) . \qquad (13.116.18)
\end{aligned}$$

This direct sum decomposition of $A^{\otimes \ell}$ is orthogonal with respect to the bilinear form $(\cdot, \cdot)_{A^{\otimes \ell}}$; that is, if α and β are two distinct almost-compositions of length ℓ, then

$$(R(G_\alpha), R(G_\beta))_{A^{\otimes \ell}} = 0. \tag{13.116.19}$$

[867] Moreover, for every almost-composition α of length ℓ, we have

$$(\varphi, \psi)_{A^{\otimes \ell}} = (\varphi, \psi)_{R(G_\alpha)} \qquad \text{for every } \varphi \in R(G_\alpha) \text{ and } \psi \in R(G_\alpha) . \tag{13.116.20}$$

[868]

[865] *Proof of (13.116.16):* Let α be an almost-composition of n. Let $\varphi \in R(G_\alpha)$ and $\psi \in R(G_n)$. We need to prove the equality (13.116.16). Since this equality is $\mathbb{Z}$-linear in each of φ and ψ, we can WLOG assume that $\varphi \in \operatorname{Irr}(G_\alpha)$ and $\psi \in \operatorname{Irr}(G_n)$ (since $\operatorname{Irr}(G_\alpha)$ and $\operatorname{Irr}(G_n)$ are $\mathbb{Z}$-module bases of $R(G_\alpha)$ and $R(G_n)$, respectively). Assume this. Thus, there exist an irreducible $\mathbb{C}G_\alpha$-module U and an irreducible $\mathbb{C}G_n$-module V such that $\varphi = \chi_U$ and $\psi = \chi_V$. Consider these U and V. We have

$$\begin{aligned}
\left(\operatorname{ind}_\alpha^n \underbrace{\varphi}_{= \chi_U}, \underbrace{\psi}_{= \chi_V}\right)_{R(G_n)} &= \left(\underbrace{\operatorname{ind}_\alpha^n \chi_U}_{= \chi_{\operatorname{ind}_\alpha^n U}}, \chi_V\right)_{R(G_n)} = \left(\chi_{\operatorname{ind}_\alpha^n U}, \chi_V\right)_{R(G_n)} \\
&= \dim_{\mathbb{C}} \operatorname{Hom}_{\mathbb{C}G_n}(\operatorname{ind}_\alpha^n U, V) = \dim_{\mathbb{C}} \operatorname{Hom}_{\mathbb{C}G_\alpha}(U, \operatorname{res}_\alpha^n V) \qquad (\text{by } (13.116.15)) .
\end{aligned}$$

Compared with

$$\left(\underbrace{\varphi}_{= \chi_U}, \operatorname{res}_\alpha^n \underbrace{\psi}_{= \chi_V}\right)_{R(G_\alpha)} = \left(\chi_U, \underbrace{\operatorname{res}_\alpha^n \chi_V}_{= \chi_{\operatorname{res}_\alpha^n V}}\right)_{R(G_\alpha)} = \left(\chi_U, \chi_{\operatorname{res}_\alpha^n V}\right)_{R(G_\alpha)} = \dim_{\mathbb{C}} \operatorname{Hom}_{\mathbb{C}G_\alpha}(U, \operatorname{res}_\alpha^n V) ,$$

this yields $(\operatorname{ind}_\alpha^n \varphi, \psi)_{R(G_n)} = (\varphi, \operatorname{res}_\alpha^n \psi)_{R(G_\alpha)}$. This proves (13.116.16).

[866] Indeed, this follows from the inductive definitions of $m^{(\ell-1)}$ and $\Delta^{(\ell-1)}$, if one recalls that the maps m and Δ are adjoint with respect to the forms $(\cdot, \cdot)_A$ and $(\cdot, \cdot)_{A \otimes A}$.

[867] This follows from the definition of $(\cdot, \cdot)_{A^{\otimes \ell}}$ and the fact that the direct sum decomposition $A = \bigoplus_{n \geq 0} R(G_n)$ is orthogonal with respect to the bilinear form $(\cdot, \cdot)_A$.

[868] *Proof of (13.116.20):* Let α be an almost-composition of length ℓ. Let $\varphi \in R(G_\alpha)$ and $\psi \in R(G_\alpha)$. We need to prove the equality (13.116.20). Since this equality is $\mathbb{Z}$-linear in each of φ and ψ, we can WLOG assume that $\varphi \in \operatorname{Irr}(G_\alpha)$ and $\psi \in \operatorname{Irr}(G_\alpha)$ (since $\operatorname{Irr}(G_\alpha)$ is a $\mathbb{Z}$-module basis of $R(G_\alpha)$). Assume this. Thus, there exist an irreducible $\mathbb{C}G_\alpha$-module V and an irreducible $\mathbb{C}G_\alpha$-module W such that $\varphi = \chi_V$ and $\psi = \chi_W$. Consider these V and W.

Write the almost-composition α in the form $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$. Since V is an irreducible representation of $G_\alpha = G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_\ell}$, we can write V in the form $V = V_1 \otimes V_2 \otimes \cdots \otimes V_\ell$, where each V_i is an irreducible representation of G_{α_i}. Similarly, We need to show that $\Delta^{(\ell-1)}\chi = \sum \operatorname{res}^n_\alpha \chi$ (where the sum ranges over all almost-compositions α of n having length ℓ). In order to do so, it is clearly enough to prove that

$$\left(\Delta^{(\ell-1)}\chi, \rho\right)_{A^{\otimes \ell}} = \left(\sum \operatorname{res}^n_\alpha \chi, \rho\right)_{A^{\otimes \ell}} \qquad \text{for every } \rho \in A^{\otimes \ell} \tag{13.116.21}$$

(since the bilinear form $(\cdot,\cdot)_{A^{\otimes \ell}}$ is nondegenerate). So, let $\rho \in A^{\otimes \ell}$. It remains to prove (13.116.21).

The equality (13.116.21) is $\mathbb{Z}$-linear in ρ. Since $\bigsqcup_{\substack{\alpha \text{ is an almost-composition} \\ \text{of length } \ell}} \operatorname{Irr}(G_\alpha)$ is a $\mathbb{Z}$-module basis of $A^{\otimes \ell}$ (this follows from (13.116.18) and the fact that each $R(G_\alpha)$ has $\mathbb{Z}$-module basis $\operatorname{Irr}(G_\alpha)$), we can therefore WLOG assume that $\rho \in \bigsqcup_{\substack{\alpha \text{ is an almost-composition} \\ \text{of length } \ell}} \operatorname{Irr}(G_\alpha)$. Assume this. Then, there exists an almost-composition β of length ℓ such that $\rho \in \operatorname{Irr}(G_\beta)$. Consider this β, and notice that $\rho \in \operatorname{Irr}(G_\beta) \subset R(G_\beta)$.

For every almost-composition α of n having length ℓ satisfying $\alpha \neq \beta$, we have

$$\left(\operatorname{res}^n_\alpha \chi, \rho\right)_{A^{\otimes \ell}} = 0 \tag{13.116.22}$$

we can write W in the form $W = W_1 \otimes W_2 \otimes \cdots \otimes W_\ell$, where each W_i is an irreducible representation of G_{α_i}. Consider these V_i and W_i.

Now, there exists a $\mathbb{C}$-vector space isomorphism

$$\begin{aligned} &\operatorname{Hom}_{\mathbb{C}G_{\alpha_1}}(V_1, W_1) \otimes \operatorname{Hom}_{\mathbb{C}G_{\alpha_2}}(V_2, W_2) \otimes \cdots \otimes \operatorname{Hom}_{\mathbb{C}G_{\alpha_\ell}}(V_\ell, W_\ell) \\ &\to \operatorname{Hom}_{\mathbb{C}[G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_\ell}]}(V_1 \otimes V_2 \otimes \cdots \otimes V_\ell, W_1 \otimes W_2 \otimes \cdots \otimes W_\ell). \end{aligned}$$

(In fact, when $\ell = 2$, the existence of such an isomorphism follows from Exercise 4.1.9(a); otherwise it follows by induction over ℓ using Exercise 4.1.9(a).) The existence of this isomorphism yields

$$\begin{aligned} &\dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}[G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_\ell}]}(V_1 \otimes V_2 \otimes \cdots \otimes V_\ell, W_1 \otimes W_2 \otimes \cdots \otimes W_\ell)\right) \\ &= \dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_{\alpha_1}}(V_1, W_1) \otimes \operatorname{Hom}_{\mathbb{C}G_{\alpha_2}}(V_2, W_2) \otimes \cdots \otimes \operatorname{Hom}_{\mathbb{C}G_{\alpha_\ell}}(V_\ell, W_\ell)\right) \\ &= \prod_{i=1}^{\ell} \underbrace{\dim_{\mathbb{C}} \operatorname{Hom}_{\mathbb{C}G_{\alpha_i}}(V_i, W_i)}_{=\left(\chi_{V_i}, \chi_{W_i}\right)_{R\left(G_{\alpha_i}\right)} = \left(\chi_{V_i}, \chi_{W_i}\right)_A} = \prod_{i=1}^{\ell} \left(\chi_{V_i}, \chi_{W_i}\right)_A \\ &= \Bigg(\underbrace{\chi_{V_1} \otimes \chi_{V_2} \otimes \cdots \otimes \chi_{V_\ell}}_{\substack{=\chi_{V_1 \otimes V_2 \otimes \cdots \otimes V_\ell} = \chi_V \\ (\text{since } V_1 \otimes V_2 \otimes \cdots \otimes V_\ell = V)}}, \underbrace{\chi_{W_1} \otimes \chi_{W_2} \otimes \cdots \otimes \chi_{W_\ell}}_{\substack{=\chi_{W_1 \otimes W_2 \otimes \cdots \otimes W_\ell} = \chi_W \\ (\text{since } W_1 \otimes W_2 \otimes \cdots \otimes W_\ell = W)}}\Bigg)_{A^{\otimes \ell}} \\ &= \Bigg(\underbrace{\chi_V}_{=\varphi}, \underbrace{\chi_W}_{=\psi}\Bigg)_{A^{\otimes \ell}} = (\varphi, \psi)_{A^{\otimes \ell}}. \end{aligned}$$

Thus,

$$\begin{aligned} &(\varphi, \psi)_{A^{\otimes \ell}} \\ &= \dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}[G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_\ell}]}(V_1 \otimes V_2 \otimes \cdots \otimes V_\ell, W_1 \otimes W_2 \otimes \cdots \otimes W_\ell)\right) \\ &= \dim_{\mathbb{C}}\left(\operatorname{Hom}_{\mathbb{C}G_\alpha}(V_1 \otimes V_2 \otimes \cdots \otimes V_\ell, W_1 \otimes W_2 \otimes \cdots \otimes W_\ell)\right) \qquad (\text{since } G_{\alpha_1} \times G_{\alpha_2} \times \cdots \times G_{\alpha_\ell} = G_\alpha) \\ &= \Bigg(\underbrace{\chi_{V_1 \otimes V_2 \otimes \cdots \otimes V_\ell}}_{\substack{=\chi_V \\ (\text{since } V_1 \otimes V_2 \otimes \cdots \otimes V_\ell = V)}}, \underbrace{\chi_{W_1 \otimes W_2 \otimes \cdots \otimes W_\ell}}_{\substack{=\chi_W \\ (\text{since } W_1 \otimes W_2 \otimes \cdots \otimes W_\ell = W)}}\Bigg)_{R(G_\alpha)} = \Bigg(\underbrace{\chi_V}_{=\varphi}, \underbrace{\chi_W}_{=\psi}\Bigg)_{R(G_\alpha)} = (\varphi, \psi)_{R(G_\alpha)}. \end{aligned}$$

This proves (13.116.20).

[869]. Now,

$$\begin{aligned}
\left(\sum \operatorname{res}^n_\alpha \chi, \rho\right)_{A^{\otimes \ell}} &= \sum \left(\operatorname{res}^n_\alpha \chi, \rho\right)_{A^{\otimes \ell}} = \left(\operatorname{res}^n_\beta \chi, \rho\right)_{A^{\otimes \ell}} + \sum_{\alpha \neq \beta} \underbrace{\left(\operatorname{res}^n_\alpha \chi, \rho\right)_{A^{\otimes \ell}}}_{\substack{=0 \\ \text{(by (13.116.22))}}} = \left(\operatorname{res}^n_\beta \chi, \rho\right)_{A^{\otimes \ell}} \\
&= \left(\operatorname{res}^n_\beta \chi, \rho\right)_{R(G_\beta)} \qquad \left(\text{by (13.116.20), applied to } \varphi = \operatorname{res}^n_\beta \chi,\ \psi = \rho \text{ and } \alpha = \beta\right) \\
&= \left(\rho, \operatorname{res}^n_\beta \chi\right)_{R(G_\beta)} \\
&= \left(\operatorname{ind}^n_\beta \rho, \chi\right)_{R(G_n)} \qquad \left(\begin{array}{c} \text{since (13.116.16) (applied } \varphi = \rho,\ \psi = \chi \text{ and } \alpha = \beta) \\ \text{yields } \left(\operatorname{ind}^n_\beta \rho, \chi\right)_{R(G_n)} = \left(\rho, \operatorname{res}^n_\beta \chi\right)_{R(G_\beta)} \end{array}\right). \qquad (13.116.23)
\end{aligned}$$

But let us write the almost-composition β as $(\beta_1, \beta_2, ..., \beta_\ell)$. Then, $\rho \in \operatorname{Irr}(G_\beta)$ is an irreducible character of $G_\beta = G_{\beta_1} \times G_{\beta_2} \times \cdots \times G_{\beta_\ell}$, and thus has the form $\rho = \rho_1 \otimes \rho_2 \otimes \cdots \otimes \rho_\ell$, where each ρ_i is an irreducible character of G_{β_i}. Consider these ρ_i. We have

$$\begin{aligned}
m^{(\ell-1)} \underbrace{\rho}_{=\rho_1 \otimes \rho_2 \otimes \cdots \otimes \rho_\ell} &= m^{(\ell-1)} \left(\rho_1 \otimes \rho_2 \otimes \cdots \otimes \rho_\ell\right) = \rho_1 \rho_2 \cdots \rho_\ell = \operatorname{ind}^n_\beta \left(\underbrace{\rho_1 \otimes \rho_2 \otimes \cdots \otimes \rho_\ell}_{=\rho}\right) \\
&\qquad \left(\text{by Exercise 4.3.11(d), applied to } \beta \text{ and } \rho_i \text{ instead of } \alpha \text{ and } \chi_i\right) \\
&= \operatorname{ind}^n_\beta \rho.
\end{aligned}$$

Now,

$$\begin{aligned}
\left(\Delta^{(\ell-1)} \chi, \rho\right)_{A^{\otimes \ell}} &= \left(\chi, \underbrace{m^{(\ell-1)} \rho}_{=\operatorname{ind}^n_\beta \rho}\right)_A \qquad \left(\text{by (13.116.17), applied to } \varphi = \chi\right) \\
&= \left(\chi, \operatorname{ind}^n_\beta \rho\right)_A = \left(\chi, \operatorname{ind}^n_\beta \rho\right)_{R(G_n)} = \left(\operatorname{ind}^n_\beta \rho, \chi\right)_{R(G_n)} \\
&= \left(\sum \operatorname{res}^n_\alpha \chi, \rho\right)_{A^{\otimes \ell}} \qquad \left(\text{by (13.116.23)}\right).
\end{aligned}$$

Thus, (13.116.21) is proven. This completes our solution of Exercise 4.3.11(e).

13.117. **Solution to Exercise 4.4.3.** *Solution to Exercise 4.4.3.* Define the Iverson bracket notation as in Exercise 4.4.3(a).

(a) Let G be a finite group. For every subset P of G, the definition of $\underline{1}_P$ yields

$$\underline{1}_P (g) = [g \in P] \qquad \text{for every } g \in G. \tag{13.117.1}$$

Also, for every subset P of G, we have

$$|P| = \sum_{k \in G} [k \in P]. \tag{13.117.2}$$

Let $h \in G$ and $g \in G$. Then, (13.117.2) (applied to $P = Z_G(h)$) yields

$$|Z_G(h)| = \sum_{k \in G} \left[\underbrace{k \in Z_G(h)}_{\substack{\text{this is equivalent to } khk^{-1} = h \\ \text{(by the definition of } Z_G(h))}} \right] = \sum_{k \in G} \left[khk^{-1} = h\right].$$

[869] since

$$\left(\underbrace{\operatorname{res}^n_\alpha \chi}_{\in R(G_\alpha)}, \underbrace{\rho}_{\in \operatorname{Irr}(G_\beta) \subset R(G_\beta)}\right)_{A^{\otimes \ell}} \in \left(R(G_\alpha), R(G_\beta)\right)_{A^{\otimes \ell}} = 0 \qquad \left(\text{by (13.116.19)}\right)$$

Applying both sides of the identity $\alpha_{G,h} = |Z_G(h)| \underline{1}_{\operatorname{Conj}_G(h)}$ to g, we obtain

$$\alpha_{G,h}(g) = \underbrace{|Z_G(h)|}_{=\sum_{k\in G}[khk^{-1}=h]} \underbrace{\underline{1}_{\operatorname{Conj}_G(h)}(g)}_{\substack{=[g\in\operatorname{Conj}_G(h)] \\ \text{(by (13.117.1), applied} \\ \text{to } P=\operatorname{Conj}_G(h))}} = \left(\sum_{k\in G}\left[khk^{-1}=h\right]\right)\left[g\in\operatorname{Conj}_G(h)\right]. \tag{13.117.3}$$

We need to prove that $\alpha_{G,h}(g) = \sum_{k\in G}\left[khk^{-1}=g\right]$. We must be in one of the following two cases:

Case 1: We have $g \in \operatorname{Conj}_G(h)$.

Case 2: We don't have $g \in \operatorname{Conj}_G(h)$.

Let us first consider Case 1. In this case, we have $g \in \operatorname{Conj}_G(h)$. Thus, there exists a $p \in G$ satisfying $g = php^{-1}$. Consider this p. Since $g = php^{-1}$, we have $h = p^{-1}gp$. Hence, (13.117.3) becomes

$$\begin{aligned}
\alpha_{G,h}(g) &= \left(\sum_{k\in G}\left[khk^{-1}=h\right]\right)\underbrace{\left[g\in\operatorname{Conj}_G(h)\right]}_{\substack{=1 \\ \text{(since } g\in\operatorname{Conj}_G(h))}} = \sum_{k\in G}\left[k\underbrace{h}_{=p^{-1}gp}k^{-1}=h\right] \\
&= \sum_{k\in G}\left[\underbrace{kp^{-1}}_{=(pk^{-1})^{-1}}gpk^{-1}=h\right] = \sum_{k\in G}\left[\left(pk^{-1}\right)^{-1}g\left(kp^{-1}\right)^{-1}=h\right] \\
&= \sum_{k\in G}\left[\underbrace{k^{-1}gk=h}_{\substack{\text{this is equivalent to} \\ khk^{-1}=g}}\right] \qquad \left(\begin{array}{c}\text{here, we have substituted } k \text{ for } pk^{-1} \text{ in the sum} \\ \text{(since the map } G\to G,\ k\mapsto pk^{-1} \text{ is a bijection)}\end{array}\right) \\
&= \sum_{k\in G}\left[khk^{-1}=g\right].
\end{aligned}$$

Thus, $\alpha_{G,h}(g) = \sum_{k\in G}\left[khk^{-1}=g\right]$ is proven in Case 1.

Let us now consider Case 2. In this case, we don't have $g \in \operatorname{Conj}_G(h)$. In other words, g is not in the conjugacy class of h. In other words, g is not conjugate to h. In other words, there exists no $k \in G$ satisfying $khk^{-1} = g$. In other words, for every $k \in G$, we do not have $khk^{-1} = g$. Hence, for every $k \in G$, we have $\left[khk^{-1}=g\right] = 0$. Thus, $\sum_{k\in G}\underbrace{\left[khk^{-1}=g\right]}_{=0} = \sum_{k\in G} 0 = 0$. Comparing this with

$$\alpha_{G,h}(g) = \left(\sum_{k\in G}\left[khk^{-1}=h\right]\right)\underbrace{\left[g\in\operatorname{Conj}_G(h)\right]}_{\substack{=0 \\ \text{(since we don't have } g\in\operatorname{Conj}_G(h))}} = 0,$$

we obtain $\alpha_{G,h}(g) = \sum_{k\in G}\left[khk^{-1}=g\right]$. Thus, $\alpha_{G,h}(g) = \sum_{k\in G}\left[khk^{-1}=g\right]$ is proven in Case 2.

Thus, $\alpha_{G,h}(g) = \sum_{k\in G}\left[khk^{-1}=g\right]$ is proven in both Cases 1 and 2. Hence, Exercise 4.4.3(a) is solved.

(b) Let H be a subgroup of a finite group G. Let $h \in H$. Let $g \in G$. Then, the definition of $\operatorname{Ind}_H^G \alpha_{H,h}$ given in Exercise 4.1.1 yields

$$\left(\operatorname{Ind}_H^G \alpha_{H,h}\right)(g) = \frac{1}{|H|} \sum_{\substack{k\in G:\\ kgk^{-1}\in H}} \alpha_{H,h}\left(kgk^{-1}\right) = \frac{1}{|H|} \sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \underbrace{\alpha_{H,h}\left(pgp^{-1}\right)}_{\substack{=\sum_{k\in H}\left[khk^{-1}=pgp^{-1}\right]\\ \text{(by Exercise 4.4.3(a), applied}\\ \text{to } H \text{ and } pgp^{-1} \text{ instead of } G \text{ and } g)}}$$

(here, we renamed the summation index k as p)

$$= \frac{1}{|H|} \underbrace{\sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \sum_{k\in H}}_{=\sum_{k\in H} \sum_{\substack{p\in G:\\ pgp^{-1}\in H}}} \left[khk^{-1} = pgp^{-1}\right] = \frac{1}{|H|} \sum_{k\in H} \sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \left[khk^{-1} = pgp^{-1}\right]. \tag{13.117.4}$$

But every $k \in H$ satisfies

$$\sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \left[khk^{-1} = pgp^{-1}\right] = \sum_{p\in G} \left[khk^{-1} = pgp^{-1}\right] \tag{13.117.5}$$

[870]. Now, (13.117.4) becomes

$$\left(\operatorname{Ind}_H^G \alpha_{H,h}\right)(g) = \frac{1}{|H|} \sum_{k\in H} \underbrace{\sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \left[khk^{-1} = pgp^{-1}\right]}_{\substack{=\sum_{p\in G}\left[khk^{-1}=pgp^{-1}\right]\\ \text{(by (13.117.5))}}} = \frac{1}{|H|} \sum_{k\in H} \sum_{p\in G} \left[\underbrace{khk^{-1} = pgp^{-1}}_{\substack{\text{this is equivalent to}\\ p^{-1}khk^{-1}p=g}}\right]$$

$$= \frac{1}{|H|} \sum_{k\in H} \sum_{p\in G} \left[p^{-1}kh \underbrace{k^{-1}p}_{=\left(p^{-1}k\right)^{-1}} = g\right] = \frac{1}{|H|} \sum_{k\in H} \sum_{p\in G} \left[p^{-1}kh\left(p^{-1}k\right)^{-1} = g\right]$$

$$= \frac{1}{|H|} \underbrace{\sum_{k\in H} \sum_{p\in G} \left[php^{-1} = g\right]}_{=|H| \sum_{p\in G}\left[php^{-1}=g\right]} \qquad \left(\begin{array}{c}\text{here, we substituted } p \text{ for } p^{-1}k \text{ in the inner sum}\\ \text{(since the map } G \to G,\ p \mapsto p^{-1}k \text{ is a bijection)}\end{array}\right)$$

$$= \frac{1}{|H|} |H| \sum_{p\in G} \left[php^{-1} = g\right] = \sum_{p\in G} \left[php^{-1} = g\right] = \sum_{k\in G} \left[khk^{-1} = g\right]$$

(here, we have substituted k for p in the sum)

$$= \alpha_{G,h}(g) \qquad \text{(by Exercise 4.4.3(a))}.$$

Let us now forget that we fixed g. We thus have proven that $\left(\operatorname{Ind}_H^G \alpha_{H,h}\right)(g) = \alpha_{G,h}(g)$ for every $g \in G$. Hence, $\operatorname{Ind}_H^G \alpha_{H,h} = \alpha_{G,h}$. This solves Exercise 4.4.3(b).

[870] *Proof of (13.117.5):* Let $k \in H$. Then,

$$\sum_{p\in G} \left[khk^{-1} = pgp^{-1}\right] = \sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \left[khk^{-1} = pgp^{-1}\right] + \sum_{\substack{p\in G:\\ pgp^{-1}\notin H}} \underbrace{\left[khk^{-1} = pgp^{-1}\right]}_{\substack{=0\\ \text{(since we don't have } khk^{-1}=pgp^{-1}\\ \text{(since } khk^{-1}\in H \text{ (since } k\in H \text{ and } h\in H) \text{ and } pgp^{-1}\notin H))}}$$

$$= \sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \left[khk^{-1} = pgp^{-1}\right] + \underbrace{\sum_{\substack{p\in G:\\ pgp^{-1}\notin H}} 0}_{=0} = \sum_{\substack{p\in G:\\ pgp^{-1}\in H}} \left[khk^{-1} = pgp^{-1}\right].$$

This proves (13.117.5).

(c) Let G_1 and G_2 be two finite groups. Let $h_1 \in G_1$ and $h_2 \in G_2$. Let $\mathbf{I}$ denote the canonical isomorphism $R_{\mathbb{C}}(G_1) \otimes R_{\mathbb{C}}(G_2) \to R_{\mathbb{C}}(G_1 \times G_2)$. We need to prove that

$$\mathbf{I}\left(\alpha_{G_1,h_1} \otimes \alpha_{G_2,h_2}\right) = \alpha_{G_1 \times G_2,(h_1,h_2)}. \tag{13.117.6}$$

Let $g \in G_1 \times G_2$. Let us write g in the form $g = (g_1, g_2)$. Then, Exercise 4.4.3(a) (applied to G_1, h_1 and g_1 instead of G, h and g) yields

$$\alpha_{G_1,h_1}(g_1) = \sum_{k \in G_1} \left[k h_1 k^{-1} = g_1\right] = \sum_{k_1 \in G_1} \left[k_1 h_1 k_1^{-1} = g_1\right]$$

(here, we have renamed the summation index k as k_1). Similarly,

$$\alpha_{G_2,h_2}(g_2) = \sum_{k_2 \in G_2} \left[k_2 h_2 k_2^{-2} = g_2\right].$$

Now,

$$\begin{aligned}
&\left(\mathbf{I}\left(\alpha_{G_1,h_1} \otimes \alpha_{G_2,h_2}\right)\right)\left(\underbrace{g}_{=(g_1,g_2)}\right) \\
&= \left(\mathbf{I}\left(\alpha_{G_1,h_1} \otimes \alpha_{G_2,h_2}\right)\right)\left((g_1,g_2)\right) = \underbrace{\alpha_{G_1,h_1}(g_1)}_{=\sum_{k_1 \in G_1}\left[k_1 h_1 k_1^{-1} = g_1\right]} \underbrace{\alpha_{G_2,h_2}(g_2)}_{=\sum_{k_2 \in G_2}\left[k_2 h_2 k_2^{-2} = g_2\right]} \qquad \text{(by the definition of } \mathbf{I}\text{)} \\
&= \left(\sum_{k_1 \in G_1} \left[k_1 h_1 k_1^{-1} = g_1\right]\right)\left(\sum_{k_2 \in G_2} \left[k_2 h_2 k_2^{-2} = g_2\right]\right) = \sum_{(k_1,k_2) \in G_1 \times G_2} \underbrace{\left[k_1 h_1 k_1^{-1} = g_1\right]\left[k_2 h_2 k_2^{-2} = g_2\right]}_{=\left[k_1 h_1 k_1^{-1} = g_1 \text{ and } k_2 h_2 k_2^{-2} = g_2\right]} \\
&= \sum_{(k_1,k_2) \in G_1 \times G_2} \left[\underbrace{k_1 h_1 k_1^{-1} = g_1 \text{ and } k_2 h_2 k_2^{-2} = g_2}_{\substack{\text{this is equivalent to} \\ \left(k_1 h_1 k_1^{-1}, k_2 h_2 k_2^{-1}\right) = (g_1,g_2)}}\right] = \sum_{(k_1,k_2) \in G_1 \times G_2} \left[\underbrace{\left(k_1 h_1 k_1^{-1}, k_2 h_2 k_2^{-1}\right)}_{=(k_1,k_2)(h_1,h_2)(k_1,k_2)^{-1}} = \underbrace{(g_1,g_2)}_{=g}\right] \\
&= \sum_{(k_1,k_2) \in G_1 \times G_2} \left[(k_1,k_2)(h_1,h_2)(k_1,k_2)^{-1} = g\right] = \sum_{k \in G_1 \times G_2} \left[k (h_1,h_2) k^{-1} = g\right]
\end{aligned}$$

(here, we have renamed the summation index (k_1, k_2) as k). Compared with

$$\alpha_{G_1 \times G_2,(h_1,h_2)}(g) = \sum_{k \in G_1 \times G_2} \left[k (h_1,h_2) k^{-1} = g\right]$$
$$\left(\text{by Exercise 4.4.3(a), applied to } G_1 \times G_2 \text{ and } (h_1,h_2) \text{ instead of } G \text{ and } h\right),$$

this yields $\left(\mathbf{I}\left(\alpha_{G_1,h_1} \otimes \alpha_{G_2,h_2}\right)\right)(g) = \alpha_{G_1 \times G_2,(h_1,h_2)}(g)$.

Now, let us forget that we fixed g. We thus have proven that $\left(\mathbf{I}\left(\alpha_{G_1,h_1} \otimes \alpha_{G_2,h_2}\right)\right)(g) = \alpha_{G_1 \times G_2,(h_1,h_2)}(g)$ for every $g \in G_1 \times G_2$. In other words, $\mathbf{I}\left(\alpha_{G_1,h_1} \otimes \alpha_{G_2,h_2}\right) = \alpha_{G_1 \times G_2,(h_1,h_2)}$. This proves (13.117.6). Exercise 4.4.3(c) is thus solved.

(d) For every partition λ, let us define $\widetilde{z}_\lambda$ as the size of the centralizer of a permutation in $\mathfrak{S}_{|\lambda|}$ having cycle type λ. Note that this does not depend on the choice of said permutation, since all permutations in $\mathfrak{S}_{|\lambda|}$ having cycle type λ are mutually conjugate (and thus their centralizers are of the same size). It is well-known that $\widetilde{z}_\lambda = z_\lambda$ (see Remark 2.5.16), but we shall avoid using this fact, as we can obtain an alternative proof of it from the following argument.

We shall use the same notations as in the proof of Theorem 4.4.1. In particular, $A_{\mathbb{C}} = \bigoplus_{n \geq 0} R_{\mathbb{C}}(\mathfrak{S}_n)$; this $\mathbb{C}$-vector space $A_{\mathbb{C}}$ becomes a $\mathbb{C}$-algebra as explained in the proof of Theorem 4.4.1. Its multiplication is given by $\operatorname{ind}_{i,j}^{i+j}$; more precisely, every $n \in \mathbb{N}$ and $m \in \mathbb{N}$, and every $\beta \in R_{\mathbb{C}}(\mathfrak{S}_n)$ and $\gamma \in R_{\mathbb{C}}(\mathfrak{S}_m)$ satisfy

$$\beta\gamma = \underbrace{\operatorname{ind}_{n,m}^{n+m}}_{=\operatorname{Ind}_{\mathfrak{S}_n \times \mathfrak{S}_m}^{\mathfrak{S}_{n+m}}} (\beta \otimes \gamma) = \operatorname{Ind}_{\mathfrak{S}_n \times \mathfrak{S}_m}^{\mathfrak{S}_{n+m}} (\beta \otimes \gamma). \tag{13.117.7}$$

We define a $\mathbb{C}$-linear map $\Phi : \Lambda_{\mathbb{C}} \to A_{\mathbb{C}}$ by setting

$$\Phi\left(p_\lambda\right) = \widetilde{z}_\lambda \underline{1}_\lambda \qquad \text{for every } \lambda \in \operatorname{Par}.$$

(This is well-defined, since $\left(p_\lambda\right)_{\lambda \in \operatorname{Par}}$ is a basis of the $\mathbb{C}$-vector space $\Lambda_{\mathbb{C}}$.) We notice that if λ is a partition of a nonnegative integer n, and if $g \in \mathfrak{S}_n$ is a permutation having cycle type λ, then

$$\Phi\left(p_\lambda\right) = \alpha_{\mathfrak{S}_n, g}. \tag{13.117.8}$$

[871] Also, if λ is a partition of a nonnegative integer n, then

$$\left|\left\{h \in \mathfrak{S}_n \mid h \text{ has cycle type } \lambda\right\}\right| = n!/\widetilde{z}_\lambda. \tag{13.117.9}$$

[872]

We shall now prove that Φ is a $\mathbb{C}$-algebra homomorphism. Since $\Phi(1) = 1$ is true[873], we only need to verify that $\Phi(uv) = \Phi(u)\Phi(v)$ for any $u \in \Lambda_{\mathbb{C}}$ and $v \in \Lambda_{\mathbb{C}}$. Let us prove this now. Fix $u \in \Lambda_{\mathbb{C}}$ and $v \in \Lambda_{\mathbb{C}}$. Since the equality $\Phi(uv) = \Phi(u)\Phi(v)$ is $\mathbb{C}$-linear in each of u and v, we can WLOG assume that u and v are elements of the basis $\left(p_\lambda\right)_{\lambda \in \operatorname{Par}}$ of the $\mathbb{C}$-vector space $\Lambda_{\mathbb{C}}$. Assume this, and set $u = p_\mu$ and $v = p_\nu$ for two partitions μ and ν. Let $n = |\mu|$ and $m = |\nu|$. Let g be a permutation in $\mathfrak{S}_n$ having cycle type μ. (Such

[871] *Proof of (13.117.8):* Let λ be a partition of a nonnegative integer n. Let $g \in \mathfrak{S}_n$ be a permutation having cycle type λ. Then, g is a permutation in $\mathfrak{S}_{|\lambda|}$ having cycle type λ. Thus, $\widetilde{z}_\lambda$ is the size of the centralizer of g (by the definition of $\widetilde{z}_\lambda$). In other words, $\widetilde{z}_\lambda = \left|Z_{\mathfrak{S}_n}(g)\right|$.

But any two permutations in $\mathfrak{S}_n$ having the same cycle type are mutually conjugate. Hence, if h is any permutation in $\mathfrak{S}_n$ having cycle type λ, then h and g are conjugate (since h and g are permutations in $\mathfrak{S}_n$ having the same cycle type). Conversely, if h is a permutation in $\mathfrak{S}_n$ such that h and g are conjugate, then h has cycle type λ (because h and g are conjugate permutations and thus have the same cycle type, but the cycle type of g is λ). Combining these two statements, we conclude that if h is a permutation in $\mathfrak{S}_n$, then h has cycle type λ if and only if h and g are conjugate. Hence,

$$\left\{h \in \mathfrak{S}_n \mid \underbrace{h \text{ has cycle type } \lambda}_{\substack{\text{this is equivalent to} \\ (h \text{ and } g \text{ are conjugate})}}\right\} = \left\{h \in \mathfrak{S}_n \mid \underbrace{h \text{ and } g \text{ are conjugate}}_{\text{this is equivalent to } h \in \operatorname{Conj}_{\mathfrak{S}_n}(g)}\right\} = \left\{h \in \mathfrak{S}_n \mid h \in \operatorname{Conj}_{\mathfrak{S}_n}(g)\right\}$$
$$= \operatorname{Conj}_{\mathfrak{S}_n}(g).$$

On the other hand, $\underline{1}_\lambda$ is defined as the characteristic function for the $\mathfrak{S}_n$-conjugacy class of permutations of cycle type λ. In other words, $\underline{1}_\lambda$ is the indicator function of the subset $\left\{h \in \mathfrak{S}_n \mid h \text{ has cycle type } \lambda\right\}$ of $\mathfrak{S}_n$. In other words, $\underline{1}_\lambda$ is the indicator function of the subset $\operatorname{Conj}_{\mathfrak{S}_n}(g)$ (since $\left\{h \in \mathfrak{S}_n \mid h \text{ has cycle type } \lambda\right\} = \operatorname{Conj}_{\mathfrak{S}_n}(g)$). In other words, $\underline{1}_\lambda = \underline{1}_{\operatorname{Conj}_{\mathfrak{S}_n}(g)}$.

Now, $\Phi\left(p_\lambda\right) = \underbrace{\widetilde{z}_\lambda}_{=\left|Z_{\mathfrak{S}_n}(g)\right|} \underbrace{\underline{1}_\lambda}_{=\underline{1}_{\operatorname{Conj}_{\mathfrak{S}_n}(g)}} = \left|Z_{\mathfrak{S}_n}(g)\right| \underline{1}_{\operatorname{Conj}_{\mathfrak{S}_n}(g)}$. Compared with $\alpha_{\mathfrak{S}_n, g} = \left|Z_{\mathfrak{S}_n}(g)\right| \underline{1}_{\operatorname{Conj}_{\mathfrak{S}_n}(g)}$ (by the definition of $\alpha_{\mathfrak{S}_n, g}$), this yields $\Phi\left(p_\lambda\right) = \alpha_{\mathfrak{S}_n, g}$. This proves (13.117.8).

[872] *Proof of (13.117.9):* Let λ be a partition of a nonnegative integer n. Fix a permutation $g \in \mathfrak{S}_n$ having cycle type λ. (Such a g clearly exists.) In the proof of (13.117.8), we have seen that $\widetilde{z}_\lambda = \left|Z_{\mathfrak{S}_n}(g)\right|$ and that $\left\{h \in \mathfrak{S}_n \mid h \text{ has cycle type } \lambda\right\} = \operatorname{Conj}_{\mathfrak{S}_n}(g)$.

Now, it is well-known that for every finite group G and every element $f \in G$, we have $\left|G / Z_G(f)\right| = \left|\operatorname{Conj}_G(f)\right|$ (in fact, there is a canonical bijection from the G-set $G / Z_G(f)$ to $\operatorname{Conj}_G(f)$, which sends the equivalence class $[\gamma] \in G / Z_G(f)$ of every $\gamma \in G$ to $\gamma f \gamma^{-1} \in \operatorname{Conj}_G(f)$). Applying this to $G = \mathfrak{S}_n$ and $f = g$, we obtain $\left|\mathfrak{S}_n / Z_{\mathfrak{S}_n}(g)\right| = \left|\operatorname{Conj}_{\mathfrak{S}_n}(g)\right|$. Thus, $\left|\operatorname{Conj}_{\mathfrak{S}_n}(g)\right| = \left|\mathfrak{S}_n / Z_{\mathfrak{S}_n}(g)\right| = \underbrace{\left|\mathfrak{S}_n\right|}_{=n!} / \underbrace{\left|Z_{\mathfrak{S}_n}(g)\right|}_{=\widetilde{z}_\lambda} = n!/\widetilde{z}_\lambda$, so that

$$n!/\widetilde{z}_\lambda = \left|\underbrace{\operatorname{Conj}_{\mathfrak{S}_n}(g)}_{=\left\{h \in \mathfrak{S}_n \mid h \text{ has cycle type } \lambda\right\}}\right| = \left|\left\{h \in \mathfrak{S}_n \mid h \text{ has cycle type } \lambda\right\}\right|.$$

This proves (13.117.9).

[873] This is because

$$\Phi\left(\underbrace{1}_{=p_\varnothing}\right) = \Phi\left(p_\varnothing\right) = \underbrace{\widetilde{z}_\varnothing}_{=1} \underbrace{\underline{1}_\varnothing}_{=1} \qquad \left(\text{by the definition of } \Phi\left(p_\varnothing\right)\right)$$
$$= 1.$$

a g clearly exists.) Let h be a permutation in $\mathfrak{S}_m$ having cycle type ν. (Such an h clearly exists.) Applying (13.117.8) to μ instead of λ, we obtain $\Phi(p_\mu) = \alpha_{\mathfrak{S}_n,g}$. Thus,

$$\Phi\left(\underbrace{u}_{=p_\mu}\right) = \Phi(p_\mu) = \alpha_{\mathfrak{S}_n,g}. \tag{13.117.10}$$

Applying (13.117.8) to ν, m and h instead of λ, n and g, we obtain $\Phi(p_\nu) = \alpha_{\mathfrak{S}_m,h}$. Thus,

$$\Phi\left(\underbrace{v}_{=p_\nu}\right) = \Phi(p_\nu) = \alpha_{\mathfrak{S}_m,h}. \tag{13.117.11}$$

The canonical isomorphism $R_{\mathbb{C}}(\mathfrak{S}_n) \otimes R_{\mathbb{C}}(\mathfrak{S}_m) \to R_{\mathbb{C}}(\mathfrak{S}_n \times \mathfrak{S}_m)$ sends $\alpha_{\mathfrak{S}_n,g} \otimes \alpha_{\mathfrak{S}_m,h}$ to $\alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}$ (according to Exercise 4.4.3(c), applied to $G_1 = \mathfrak{S}_n$, $G_2 = \mathfrak{S}_m$, $h_1 = g$ and $h_2 = h$). Let us identify $R_{\mathbb{C}}(\mathfrak{S}_n) \otimes R_{\mathbb{C}}(\mathfrak{S}_m)$ with $R_{\mathbb{C}}(\mathfrak{S}_n \times \mathfrak{S}_m)$ along this isomorphism. Then, the statement we just made rewrites as follows:

$$\alpha_{\mathfrak{S}_n,g} \otimes \alpha_{\mathfrak{S}_m,h} = \alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}. \tag{13.117.12}$$

Now, multiplying the equalities (13.117.10) and (13.117.11), we obtain

$$\begin{aligned}
\Phi(u)\Phi(v) &= \alpha_{\mathfrak{S}_n,g}\alpha_{\mathfrak{S}_m,h} \\
&= \operatorname{Ind}_{\mathfrak{S}_n \times \mathfrak{S}_m}^{\mathfrak{S}_{n+m}} \underbrace{(\alpha_{\mathfrak{S}_n,g} \otimes \alpha_{\mathfrak{S}_m,h})}_{\substack{=\alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)} \\ \text{(by (13.117.12))}}} \\
&\qquad \left(\text{by (13.117.7), applied to } \beta = \alpha_{\mathfrak{S}_n,g} \text{ and } \gamma = \alpha_{\mathfrak{S}_m,h}\right) \\
&= \operatorname{Ind}_{\mathfrak{S}_n \times \mathfrak{S}_m}^{\mathfrak{S}_{n+m}} \alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)} = \alpha_{\mathfrak{S}_{n+m},(g,h)} \qquad (13.117.13)
\end{aligned}$$

(by Exercise 4.4.3(b), applied to $\mathfrak{S}_{n+m}$, $\mathfrak{S}_n \times \mathfrak{S}_m$ and (g,h) instead of G, H and h).

Let λ be the partition whose parts are $\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}, \nu_1, \nu_2, \ldots, \nu_{\ell(\nu)}$. Then, $(\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)})$ is a permutation of the list $(\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}, \nu_1, \nu_2, \ldots, \nu_{\ell(\nu)})$, and the partition λ has size

$$|\lambda| = \underbrace{\mu_1 + \mu_2 + \cdots + \mu_{\ell(\mu)}}_{=|\mu|=n} + \underbrace{\nu_1 + \nu_2 + \cdots + \nu_{\ell(\nu)}}_{=|\nu|=m} = n + m.$$

We also have $p_\lambda = p_\mu p_\nu$ [874]. Since $p_\mu = u$ and $p_\nu = v$, this rewrites as $p_\lambda = uv$.

Recall that the permutation g has cycle type μ. In other words, the cycles of g have lengths μ_1, μ_2, $\ldots$, $\mu_{\ell(\mu)}$. Similarly, the cycles of h have lengths ν_1, ν_2, $\ldots$, $\nu_{\ell(\nu)}$. Hence, the cycles of the permutation $(g,h) \in \mathfrak{S}_{n+m}$ (which, as we recall, sends every $i \in \{1, 2, \ldots, n+m\}$ to $\begin{cases} g(i), & \text{if } i \leq n; \\ n + h(i-n), & \text{if } i > n \end{cases}$) have lengths μ_1, μ_2, $\ldots$, $\mu_{\ell(\mu)}$, ν_1, ν_2, $\ldots$, $\nu_{\ell(\nu)}$ (in fact, on the subset $\{1, 2, \ldots, n\}$ of $\{1, 2, \ldots, n+m\}$, the permutation (g,h) acts as g and thus has cycles of lengths μ_1, μ_2, $\ldots$, $\mu_{\ell(\mu)}$, whereas on the complementary subset $\{n+1, n+2, \ldots, n+m\}$ of $\{1, 2, \ldots, n+m\}$, the permutation (g,h) acts as (a shifted version of) h and thus has cycles of lengths ν_1, ν_2, $\ldots$, $\nu_{\ell(\nu)}$). In other words, the cycles of the permutation $(g,h) \in \mathfrak{S}_{n+m}$ have lengths λ_1, λ_2, $\ldots$, $\lambda_{\ell(\lambda)}$ (since $(\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)})$ is a permutation of the list $(\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}, \nu_1, \nu_2, \ldots, \nu_{\ell(\nu)})$). In other words, the permutation $(g,h) \in \mathfrak{S}_{n+m}$ has cycle type λ. Thus, (13.117.8) (applied to $n+m$ and (g,h) instead of n and g) yields $\Phi(p_\lambda) = \alpha_{\mathfrak{S}_{n+m},(g,h)}$. Compared with (13.117.13), this yields $\Phi(u)\Phi(v) = \Phi(p_\lambda)$. Since $p_\lambda = uv$, this rewrites as $\Phi(u)\Phi(v) = \Phi(uv)$. Thus,

[874] *Proof.* By the definition of p_μ, we have $p_\mu = p_{\mu_1} p_{\mu_2} \cdots p_{\mu_{\ell(\mu)}}$. Similarly, $p_\nu = p_{\nu_1} p_{\nu_2} \cdots p_{\nu_{\ell(\nu)}}$. Multiplying these two equalities, we obtain $p_\mu p_\nu = \left(p_{\mu_1} p_{\mu_2} \cdots p_{\mu_{\ell(\mu)}}\right)\left(p_{\nu_1} p_{\nu_2} \cdots p_{\nu_{\ell(\nu)}}\right)$.

But the definition of p_λ yields $p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_{\ell(\lambda)}}$. The product $p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_{\ell(\lambda)}}$ has the same factors as the product $p_{\mu_1} p_{\mu_2} \cdots p_{\mu_{\ell(\mu)}} p_{\nu_1} p_{\nu_2} \cdots p_{\nu_{\ell(\nu)}}$ but possibly in a different order (since $(\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)})$ is a permutation of the list $(\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}, \nu_1, \nu_2, \ldots, \nu_{\ell(\nu)})$). Hence, $p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_{\ell(\lambda)}} = p_{\mu_1} p_{\mu_2} \cdots p_{\mu_{\ell(\mu)}} p_{\nu_1} p_{\nu_2} \cdots p_{\nu_{\ell(\nu)}}$, so that

$$p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_{\ell(\lambda)}} = p_{\mu_1} p_{\mu_2} \cdots p_{\mu_{\ell(\mu)}} p_{\nu_1} p_{\nu_2} \cdots p_{\nu_{\ell(\nu)}} = \left(p_{\mu_1} p_{\mu_2} \cdots p_{\mu_{\ell(\mu)}}\right)\left(p_{\nu_1} p_{\nu_2} \cdots p_{\nu_{\ell(\nu)}}\right) = p_\mu p_\nu,$$

qed.

$\Phi(uv) = \Phi(u)\Phi(v)$ is proven. As explained, this completes the proof of the fact that Φ is a $\mathbb{C}$-algebra homomorphism.

But we know that $\operatorname{ch} : A \to \Lambda$ is a $\mathbb{Z}$-Hopf algebra isomorphism, and thus the extension of ch to a $\mathbb{C}$-linear map $A_{\mathbb{C}} \to \Lambda_{\mathbb{C}}$ is a $\mathbb{C}$-Hopf algebra isomorphism. We shall denote this extension by $\operatorname{ch}_{\mathbb{C}}$.

We now shall show that $\operatorname{ch}_{\mathbb{C}} \circ \Phi = \operatorname{id}_{\Lambda_{\mathbb{C}}}$. Indeed, let n be a positive integer. Then, $\widetilde{z}_{(n)} = n$ [875]. Now, the definition of $\Phi\left(p_{(n)}\right)$ yields $\Phi\left(p_{(n)}\right) = \underbrace{\widetilde{z}_{(n)}}_{=n} \underline{1}_{(n)} = n\underline{1}_{(n)}$, so that

$$\left(\operatorname{ch}_{\mathbb{C}} \circ \Phi\right)(p_n) = \operatorname{ch}_{\mathbb{C}}\left(\Phi\left(\underbrace{p_n}_{=p_{(n)}}\right)\right) = \operatorname{ch}_{\mathbb{C}}\left(\underbrace{\Phi\left(p_{(n)}\right)}_{=n\underline{1}_{(n)}}\right) = \operatorname{ch}_{\mathbb{C}}\left(n\underline{1}_{(n)}\right) = n \underbrace{\operatorname{ch}_{\mathbb{C}}\left(\underline{1}_{(n)}\right)}_{\substack{=\frac{p_n}{n} \\ \text{(by a part of Theorem 4.4.1} \\ \text{that is already proven)}}}$$
$$= n \cdot \frac{p_n}{n} = p_n = \operatorname{id}_{\Lambda_{\mathbb{C}}}(p_n).$$

Now, let us forget that we fixed n. We thus have shown that $\left(\operatorname{ch}_{\mathbb{C}} \circ \Phi\right)(p_n) = \operatorname{id}_{\Lambda_{\mathbb{C}}}(p_n)$ for every positive integer n. Thus, the $\mathbb{C}$-algebra homomorphisms $\operatorname{ch}_{\mathbb{C}} \circ \Phi$ and $\operatorname{id}_{\Lambda_{\mathbb{C}}}$ are equal to each other on p_n for every positive integer n. Since $(p_n)_{n \geq 1}$ is a generating set of the $\mathbb{C}$-algebra $\Lambda_{\mathbb{C}}$, this yields that these homomorphisms are equal to each other on a generating set of the $\mathbb{C}$-algebra $\Lambda_{\mathbb{C}}$. Hence, these homomorphisms must be identical. That is, we have $\operatorname{ch}_{\mathbb{C}} \circ \Phi = \operatorname{id}_{\Lambda_{\mathbb{C}}}$.

Since $\operatorname{ch}_{\mathbb{C}}$ is an isomorphism, this yields that Φ is the inverse of $\operatorname{ch}_{\mathbb{C}}$. That is, $\Phi = \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}$.

Corollary 2.5.17(b) (applied to $\mathbf{k} = \mathbb{C}$) yields that $\{p_\lambda\}$ and $\left\{z_\lambda^{-1} p_\lambda\right\}$ are dual bases of $\Lambda_{\mathbb{C}}$ with respect to the Hall inner product on Λ. Thus,

$$\left(p_\lambda, z_\mu^{-1} p_\mu\right)_{\Lambda_{\mathbb{C}}} = \delta_{\lambda,\mu} \qquad \text{for any partitions } \lambda \text{ and } \mu. \tag{13.117.15}$$

[875] *Proof.* Let g denote the n-cycle $(1, 2, \ldots, n)$ in $\mathfrak{S}_n$. Then, g is a permutation in $\mathfrak{S}_n$ having cycle type (n). But $\widetilde{z}_{(n)}$ is defined as the size of the centralizer of a permutation in $\mathfrak{S}_{|(n)|}$ having cycle type (n). Hence, $\widetilde{z}_{(n)}$ is the size of the centralizer of g in $\mathfrak{S}_n$ (since g is a permutation in $\mathfrak{S}_n = \mathfrak{S}_{|(n)|}$ having cycle type (n)). In other words, $\widetilde{z}_{(n)} = \left|Z_{\mathfrak{S}_n}(g)\right|$.

It is clear that the subgroup $\langle g \rangle$ of $\mathfrak{S}_n$ generated by g satisfies $\langle g \rangle \subset Z_{\mathfrak{S}_n}(g)$ (since every power of g centralizes g). We shall now show that $\langle g \rangle = Z_{\mathfrak{S}_n}(g)$.

Indeed, let $z \in Z_{\mathfrak{S}_n}(g)$. Then, z must centralize g. That is, we have $zgz^{-1} = g$. Hence, $zg = gz$, so that the elements g and z of $\mathfrak{S}_n$ commute. Hence, these elements z and g generate a commutative subgroup of $\mathfrak{S}_n$. Denote this subgroup by T.

Now, every $i \in \{1, 2, \ldots, n\}$ satisfies

$$g^{i-1}(1) = i \tag{13.117.14}$$

(since g is the n-cycle $(1, 2, \ldots, n)$). Now, let $j = z(1)$. Then, $g^{j-1}(1) = j$ (by (13.117.14), applied to $i = j$). On the other hand, let $i \in \{1, 2, \ldots, n\}$. Then, g^{i-1} commutes with z (since g commutes with z); in other words, $g^{i-1}z = zg^{i-1}$. Now,

$$z\left(\underbrace{i}_{\substack{=g^{i-1}(1) \\ \text{(by (13.117.14))}}}\right) = z\left(g^{i-1}(1)\right) = \underbrace{\left(zg^{i-1}\right)}_{=g^{i-1}z}(1) = \left(g^{i-1}z\right)(1) = g^{i-1}\left(\underbrace{z(1)}_{=j=g^{j-1}(1)}\right)$$
$$= g^{i-1}\left(g^{j-1}(1)\right) = \underbrace{\left(g^{i-1}g^{j-1}\right)}_{=g^{(i-1)+(j-1)}=g^{j-1}g^{i-1}}(1) = \left(g^{j-1}g^{i-1}\right)(1) = g^{j-1}\left(\underbrace{g^{i-1}(1)}_{\substack{=i \\ \text{(by (13.117.14))}}}\right) = g^{j-1}(i).$$

Let us now forget that we fixed i. We thus have shown that $z(i) = g^{j-1}(i)$ for every $i \in \{1, 2, \ldots, n\}$. Hence, $z = g^{j-1} \in \langle g \rangle$.

Now, let us forget that we fixed z. We thus have proven that $z \in \langle g \rangle$ for every $z \in Z_{\mathfrak{S}_n}(g)$. Hence, $Z_{\mathfrak{S}_n}(g) \subset \langle g \rangle$. Combined with $\langle g \rangle \subset Z_{\mathfrak{S}_n}(g)$, this yields $\langle g \rangle = Z_{\mathfrak{S}_n}(g)$. Hence, $|\langle g \rangle| = \left|Z_{\mathfrak{S}_n}(g)\right|$. Compared with $\widetilde{z}_{(n)} = \left|Z_{\mathfrak{S}_n}(g)\right|$, this yields $\widetilde{z}_{(n)} = |\langle g \rangle| = (\text{the order of } g \text{ in } \mathfrak{S}_n) = n$ (since g is an n-cycle), qed.

Hence, every partition λ satisfies

$$\left(p_\lambda, \underbrace{p_\lambda}_{=z_\lambda z_\lambda^{-1} p_\lambda}\right)_{\Lambda_{\mathbb{C}}} = \left(p_\lambda, z_\lambda z_\lambda^{-1} p_\lambda\right)_{\Lambda_{\mathbb{C}}} = z_\lambda \underbrace{\left(p_\lambda, z_\lambda^{-1} p_\lambda\right)_{\Lambda_{\mathbb{C}}}}_{\substack{=\delta_{\lambda,\lambda} \\ \text{(by (13.117.15), applied} \\ \text{to } \mu=\lambda)}} = z_\lambda \underbrace{\delta_{\lambda,\lambda}}_{=1} = z_\lambda. \tag{13.117.16}$$

Our goal is to prove that $\operatorname{ch}_{\mathbb{C}}(\underline{1}_\lambda) = \dfrac{p_\lambda}{z_\lambda}$ for every partition λ.

Let λ be a partition. Let n be the size of λ. Then, $\lambda \in \operatorname{Par}_n \subset \operatorname{Par}$ and $\underline{1}_\lambda \in R_{\mathbb{C}}(\mathfrak{S}_n)$. We know that $\widetilde{z}_\lambda$ is a positive integer (since $\widetilde{z}_\lambda$ is defined as the size of a centralizer, and centralizers are subgroups). Hence, we can divide by $\widetilde{z}_\lambda$, and we have

$$\Phi\left(\widetilde{z}_\lambda^{-1} p_\lambda\right) = \widetilde{z}_\lambda^{-1} \underbrace{\Phi(p_\lambda)}_{\substack{=\widetilde{z}_\lambda \underline{1}_\lambda \\ \text{(by the definition of } \Phi(p_\lambda))}} = \widetilde{z}_\lambda^{-1} \widetilde{z}_\lambda \underline{1}_\lambda = \underline{1}_\lambda.$$

Since $\Phi = (\operatorname{ch}_{\mathbb{C}})^{-1}$, this rewrites as $(\operatorname{ch}_{\mathbb{C}})^{-1}\left(\widetilde{z}_\lambda^{-1} p_\lambda\right) = \underline{1}_\lambda$. Hence,

$$\operatorname{ch}_{\mathbb{C}}(\underline{1}_\lambda) = \widetilde{z}_\lambda^{-1} p_\lambda. \tag{13.117.17}$$

Recall that we want to prove that $\operatorname{ch}_{\mathbb{C}}(\underline{1}_\lambda) = \dfrac{p_\lambda}{z_\lambda}$. If we can show that $\widetilde{z}_\lambda = z_\lambda$, then (13.117.17) becomes $\operatorname{ch}_{\mathbb{C}}(\underline{1}_\lambda) = \left(\underbrace{\widetilde{z}_\lambda}_{=z_\lambda}\right)^{-1} p_\lambda = z_\lambda^{-1} p_\lambda = \dfrac{p_\lambda}{z_\lambda}$, and thus $\operatorname{ch}_{\mathbb{C}}(\underline{1}_\lambda) = \dfrac{p_\lambda}{z_\lambda}$ will be proven. Hence, all that remains to be done is proving $\widetilde{z}_\lambda = z_\lambda$.

But ch is a PSH-isomorphism, thus an isometry. Hence, $\operatorname{ch}_{\mathbb{C}}$ (being the extension of ch to a $\mathbb{C}$-linear map) must also be an isometry, i.e., we must have

$$(\operatorname{ch}_{\mathbb{C}} \beta, \operatorname{ch}_{\mathbb{C}} \gamma)_{\Lambda_{\mathbb{C}}} = (\beta, \gamma)_{A_{\mathbb{C}}} \qquad \text{for all } \beta \in A_{\mathbb{C}} \text{ and } \gamma \in A_{\mathbb{C}}.$$

Applying this to $\beta = \underline{1}_\lambda$ and $\gamma = \underline{1}_\lambda$, we obtain

$$\begin{aligned}
&(\operatorname{ch}_{\mathbb{C}}(\underline{1}_\lambda), \operatorname{ch}_{\mathbb{C}}(\underline{1}_\lambda))_{\Lambda_{\mathbb{C}}} \\
&= (\underline{1}_\lambda, \underline{1}_\lambda)_{A_{\mathbb{C}}} = \langle \underline{1}_\lambda, \underline{1}_\lambda \rangle_{\mathfrak{S}_n} \qquad \left(\begin{array}{c}\text{since } \underline{1}_\lambda \in R_{\mathbb{C}}(\mathfrak{S}_n)\text{, and since the bilinear form} \\ (\cdot,\cdot)_{A_{\mathbb{C}}} \text{ on } A_{\mathbb{C}} \text{ extends the bilinear form } \langle\cdot,\cdot\rangle_{\mathfrak{S}_n} \text{ on } R_{\mathbb{C}}(\mathfrak{S}_n)\end{array}\right) \\
&= \underbrace{\frac{1}{|\mathfrak{S}_n|}}_{=\frac{1}{n!}} \sum_{g \in \mathfrak{S}_n} \underbrace{\underline{1}_\lambda(g)}_{\substack{=[g \text{ has cycle type } \lambda] \\ \text{(by the definition of } \underline{1}_\lambda)}} \underbrace{\underline{1}_\lambda(g^{-1})}_{\substack{=[g^{-1} \text{ has cycle type } \lambda] \\ \text{(by the definition of } \underline{1}_\lambda)}} \qquad \left(\text{by the definition of the bilinear form } \langle\cdot,\cdot\rangle_{\mathfrak{S}_n}\right) \\
&= \frac{1}{n!} \sum_{g \in \mathfrak{S}_n} [g \text{ has cycle type } \lambda] \left[\underbrace{g^{-1} \text{ has cycle type } \lambda}_{\substack{\text{this is equivalent to} \\ (g \text{ has cycle type } \lambda) \\ \text{(since the cycle type of } g^{-1} \\ \text{equals the cycle type of } g)}}\right] = \frac{1}{n!} \sum_{g \in \mathfrak{S}_n} \underbrace{[g \text{ has cycle type } \lambda][g \text{ has cycle type } \lambda]}_{\substack{=[(g \text{ has cycle type } \lambda) \text{ and } (g \text{ has cycle type } \lambda)] \\ =[g \text{ has cycle type } \lambda]}} \\
&= \frac{1}{n!} \underbrace{\sum_{g \in \mathfrak{S}_n} [g \text{ has cycle type } \lambda]}_{\substack{=|\{h \in \mathfrak{S}_n \mid h \text{ has cycle type } \lambda\}| = n!/\widetilde{z}_\lambda \\ \text{(by (13.117.9))}}} = \frac{1}{n!} \cdot \frac{n!}{\widetilde{z}_\lambda} = \frac{1}{\widetilde{z}_\lambda}.
\end{aligned}$$

Hence,

$$\frac{1}{\widetilde{z}_\lambda} = \left(\underbrace{\operatorname{ch}_{\mathbb{C}}\left(\underline{1}_\lambda\right)}_{\substack{=\widetilde{z}_\lambda^{-1} p_\lambda \\ \text{(by (13.117.17))}}} , \underbrace{\operatorname{ch}_{\mathbb{C}}\left(\underline{1}_\lambda\right)}_{\substack{=\widetilde{z}_\lambda^{-1} p_\lambda \\ \text{(by (13.117.17))}}} \right)_{\Lambda_{\mathbb{C}}} = \left(\widetilde{z}_\lambda^{-1} p_\lambda, \widetilde{z}_\lambda^{-1} p_\lambda\right)_{\Lambda_{\mathbb{C}}} = \left(\widetilde{z}_\lambda^{-1}\right)^2 \left(p_\lambda, p_\lambda\right)_{\Lambda_{\mathbb{C}}}.$$

Multiplying this equality with $\widetilde{z}_\lambda^2$, we obtain

$$\widetilde{z}_\lambda = \left(p_\lambda, p_\lambda\right)_{\Lambda_{\mathbb{C}}} = z_\lambda \qquad \text{(by (13.117.16))}.$$

Thus, $\widetilde{z}_\lambda = z_\lambda$ is proven. As we have explained, this concludes the proof of $\operatorname{ch}_{\mathbb{C}}\left(\underline{1}_\lambda\right) = \frac{p_\lambda}{z_\lambda}$, and thus Exercise 4.4.3(d) is solved.

(e) Let λ be a partition. Let us work with the notations of the solution of Exercise 4.4.3(d) above. In the latter solution, we have shown that $\widetilde{z}_\lambda = z_\lambda$. Thus,

$$\begin{aligned} z_\lambda = \widetilde{z}_\lambda &= \left(\text{the size of the centralizer of a permutation in } \mathfrak{S}_{|\lambda|} \text{ having cycle type } \lambda\right) \\ &\qquad \left(\text{by the definition of } \widetilde{z}_\lambda\right) \\ &= \left(\text{the size of the centralizer in } \mathfrak{S}_n \text{ of a permutation having cycle type } \lambda, \text{ where } n = |\lambda|\right). \end{aligned}$$

This proves Remark 2.5.16. Thus, Exercise 4.4.3(e) is solved.

(f) Let G and H be two finite groups. Let $\rho : H \to G$ be a group homomorphism. Let $y \in H$. We shall show that $\operatorname{Ind}_\rho \alpha_{H,y} = \alpha_{G,\rho(y)}$.

Let $u \in G$. Then, the definition of $\operatorname{Ind}_\rho \alpha_{H,y}$ yields

$$\begin{aligned} \left(\operatorname{Ind}_\rho \alpha_{H,y}\right)(u) &= \frac{1}{|H|} \sum_{\substack{(h,k) \in H \times G; \\ k\rho(h)k^{-1} = u}} \alpha_{H,y}(h) = \frac{1}{|H|} \sum_{\substack{(h,x) \in H \times G; \\ x\rho(h)x^{-1} = u}} \underbrace{\alpha_{H,y}(h)}_{\substack{= \sum_{k \in H} \left[kyk^{-1} = h\right] \\ \text{(by Exercise 4.4.3(a), applied to} \\ H,\ y \text{ and } h \text{ instead of } G,\ h \text{ and } g)}} \\ &\qquad \left(\text{here, we renamed the summation index } (h,k) \text{ as } (h,x)\right) \\ &= \frac{1}{|H|} \underbrace{\sum_{\substack{(h,x) \in H \times G; \\ x\rho(h)x^{-1} = u}}}_{= \sum_{x \in G} \sum_{\substack{h \in H; \\ x\rho(h)x^{-1} = u}}} \sum_{k \in H} \left[kyk^{-1} = h\right] \\ &= \frac{1}{|H|} \sum_{x \in G} \underbrace{\sum_{\substack{h \in H; \\ x\rho(h)x^{-1} = u}} \sum_{k \in H}}_{= \sum_{k \in H} \sum_{\substack{h \in H; \\ x\rho(h)x^{-1} = u}}} \left[kyk^{-1} = h\right] \\ &= \frac{1}{|H|} \sum_{x \in G} \sum_{k \in H} \sum_{\substack{h \in H; \\ x\rho(h)x^{-1} = u}} \left[kyk^{-1} = h\right]. \end{aligned} \tag{13.117.18}$$

But every $x \in G$ and $k \in H$ satisfy

$$\sum_{\substack{h \in H; \\ x\rho(h)x^{-1} = u}} \left[kyk^{-1} = h\right] = \left[x\rho(k)\rho(y)\left(x\rho(k)\right)^{-1} = u\right] \tag{13.117.19}$$

[876]. Hence, (13.117.18) becomes

$$\begin{aligned}
\left(\operatorname{Ind}_\rho \alpha_{H,y}\right)(u) &= \frac{1}{|H|} \underbrace{\sum_{x\in G}\sum_{k\in H}}_{=\sum_{k\in H}\sum_{x\in G}} \underbrace{\sum_{\substack{h\in H;\\ x\rho(h)x^{-1}=u}} \left[kyk^{-1}=h\right]}_{\substack{=\left[x\rho(k)\rho(y)(x\rho(k))^{-1}=u\right]\\ \text{(by (13.117.19))}}} \\
&= \frac{1}{|H|}\sum_{k\in H} \underbrace{\sum_{x\in G}\left[x\rho(k)\rho(y)(x\rho(k))^{-1}=u\right]}_{\substack{=\sum_{x\in G}\left[x\rho(y)x^{-1}=u\right]\\ \text{(here, we have substituted } x \text{ for } x\rho(k) \text{ in the sum}\\ \text{(because the map } G\to G,\ x\mapsto x\rho(k) \text{ is a bijection}\\ \text{(since } G \text{ is a group, and since } \rho(k)\in G)))}} = \frac{1}{|H|} \underbrace{\sum_{k\in H}\sum_{x\in G}\left[x\rho(y)x^{-1}=u\right]}_{=|H|\cdot\sum_{x\in G}\left[x\rho(y)x^{-1}=u\right]} \\
&= \frac{1}{|H|}|H|\cdot\sum_{x\in G}\left[x\rho(y)x^{-1}=u\right] = \sum_{x\in G}\left[x\rho(y)x^{-1}=u\right] \\
&= \sum_{k\in G}\left[k\rho(y)k^{-1}=u\right] \qquad \text{(here, we renamed the summation index } x \text{ as } k).
\end{aligned}$$

Compared with

$$\alpha_{G,\rho(y)}(u) = \sum_{k\in G}\left[k\rho(y)k^{-1}=u\right] \qquad \text{(by Exercise 4.4.3(a), applied to } \rho(y) \text{ and } u \text{ instead of } h \text{ and } g),$$

[876] *Proof of (13.117.19):* Let $x\in G$ and $k\in H$. We have

$$\begin{aligned}
&\sum_{h\in H}\left[x\rho(h)x^{-1}=u\right]\left[kyk^{-1}=h\right] \\
&= \sum_{\substack{h\in H;\\ x\rho(h)x^{-1}=u}} \underbrace{\left[x\rho(h)x^{-1}=u\right]}_{\substack{=1\\ \text{(since we have } x\rho(h)x^{-1}=u)}} \left[kyk^{-1}=h\right] + \sum_{\substack{h\in H;\\ x\rho(h)x^{-1}\neq u}} \underbrace{\left[x\rho(h)x^{-1}=u\right]}_{\substack{=0\\ \text{(since we don't have } x\rho(h)x^{-1}=u\\ \text{(since } x\rho(h)x^{-1}\neq u))}} \left[kyk^{-1}=h\right] \\
&= \sum_{\substack{h\in H;\\ x\rho(h)x^{-1}=u}} \left[kyk^{-1}=h\right] + \underbrace{\sum_{\substack{h\in H;\\ x\rho(h)x^{-1}\neq u}} 0\left[kyk^{-1}=h\right]}_{=0} = \sum_{\substack{h\in H;\\ x\rho(h)x^{-1}=u}} \left[kyk^{-1}=h\right],
\end{aligned}$$

so that

$$\begin{aligned}
\sum_{\substack{h\in H;\\ x\rho(h)x^{-1}=u}} \left[kyk^{-1}=h\right] &= \sum_{h\in H}\left[x\rho(h)x^{-1}=u\right]\left[kyk^{-1}=h\right] \\
&= \sum_{\substack{h\in H;\\ h=kyk^{-1}}}\left[x\rho(h)x^{-1}=u\right] \underbrace{\left[kyk^{-1}=h\right]}_{\substack{=1\\ \text{(since we have } kyk^{-1}=h\\ \text{(since } h=kyk^{-1}))}} + \sum_{\substack{h\in H;\\ h\neq kyk^{-1}}}\left[x\rho(h)x^{-1}=u\right] \underbrace{\left[kyk^{-1}=h\right]}_{\substack{=0\\ \text{(since we don't have } kyk^{-1}=h\\ \text{(since } kyk^{-1}\neq h \text{ (since } h\neq kyk^{-1})))}} \\
&= \sum_{\substack{h\in H;\\ h=kyk^{-1}}}\left[x\rho(h)x^{-1}=u\right] + \underbrace{\sum_{\substack{h\in H;\\ h\neq kyk^{-1}}}\left[x\rho(h)x^{-1}=u\right]0}_{=0} = \sum_{\substack{h\in H;\\ h=kyk^{-1}}}\left[x\rho(h)x^{-1}=u\right] \\
&= \left[x \underbrace{\rho\left(kyk^{-1}\right)}_{\substack{=\rho(k)\rho(y)(\rho(k))^{-1}\\ \text{(since } \rho \text{ is a group}\\ \text{homomorphism)}}} x^{-1}=u\right] \qquad \left(\text{since } kyk^{-1}\in H \text{ (since } k\in H \text{ and } y\in H)\right) \\
&= \left[x\rho(k)\rho(y)\underbrace{(\rho(k))^{-1}x^{-1}}_{=(x\rho(k))^{-1}}=u\right] = \left[x\rho(k)\rho(y)(x\rho(k))^{-1}=u\right].
\end{aligned}$$

This proves (13.117.19).

this yields $\left(\operatorname{Ind}_\rho \alpha_{H,y}\right)(u) = \alpha_{G,\rho(y)}(u)$.

Let us now forget that we fixed u. We thus have shown that $\left(\operatorname{Ind}_\rho \alpha_{H,y}\right)(u) = \alpha_{G,\rho(y)}(u)$ for every $u \in G$. In other words, $\operatorname{Ind}_\rho \alpha_{H,y} = \alpha_{G,\rho(y)}$.

Let us now forget that we fixed y. We thus have shown that $\operatorname{Ind}_\rho \alpha_{H,y} = \alpha_{G,\rho(y)}$ for every $y \in H$. Renaming y as h in this statement, we obtain that $\operatorname{Ind}_\rho \alpha_{H,h} = \alpha_{G,\rho(h)}$ for every $h \in H$. This solves Exercise 4.4.3(f).

13.118. **Solution to Exercise 4.4.4.** *Solution to Exercise 4.4.4.*

Step 1: Study of inner tensor products.

The well-definedness of the inner tensor product is clear (since the inclusion map $G \to G \times G,\ g \mapsto (g, g)$ is a group homomorphism). We notice that if G is a group and U_1 and U_2 are two $\mathbb{C}G$-modules, then the character $\chi_{U_1 \otimes U_2}$ of the inner tensor product $U_1 \otimes U_2$ of U_1 and U_2 is given by

$$\chi_{U_1 \otimes U_2}(g) = \chi_{U_1}(g)\,\chi_{U_2}(g) \qquad \text{for all } g \in G. \tag{13.118.1}$$

[877]

Step 2: The involutions $\widetilde{\omega}_n$.

Now let $n \geq 0$. For every $f \in R_{\mathbb{C}}(\mathfrak{S}_n)$, it is easy to see that the map $\mathfrak{S}_n \to \mathbb{C}$ which sends every $g \in \mathfrak{S}_n$ to $\operatorname{sgn}(g) f(g)$ is a class function (because both $\operatorname{sgn}(g)$ and $f(g)$ are uniquely determined by the conjugacy class of g). This class function $\mathfrak{S}_n \to \mathbb{C}$ is denoted by $\operatorname{sgn}_{\mathfrak{S}_n} * f$ and belongs to $R_{\mathbb{C}}(\mathfrak{S}_n)$ (being a class function). We can thus define a map $\widetilde{\omega}_n : R_{\mathbb{C}}(\mathfrak{S}_n) \to R_{\mathbb{C}}(\mathfrak{S}_n)$ as follows:

$$\widetilde{\omega}_n(f) = \operatorname{sgn}_{\mathfrak{S}_n} * f \qquad \text{for all } f \in R_{\mathbb{C}}(\mathfrak{S}_n).$$

Consider this map $\widetilde{\omega}_n$. It is $\mathbb{C}$-linear (obviously) and an involution[878]. Hence, $\widetilde{\omega}_n$ is precisely the involution on class functions $f : \mathfrak{S}_n \to \mathbb{C}$ sending $f \mapsto \operatorname{sgn}_{\mathfrak{S}_n} * f$.

Now, let V be any finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module. Then, every $g \in \mathfrak{S}_n$ satisfies

$$\underbrace{\left(\widetilde{\omega}_n(\chi_V)\right)}_{\substack{=\operatorname{sgn}_{\mathfrak{S}_n} * \chi_V \\ \text{(by the definition of } \widetilde{\omega}_n)}}(g) = \left(\operatorname{sgn}_{\mathfrak{S}_n} * \chi_V\right)(g) = \operatorname{sgn}(g)\,\chi_V(g)$$

and

$$\chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V}(g) = \underbrace{\chi_{\operatorname{sgn}_{\mathfrak{S}_n}}(g)}_{=\operatorname{sgn}(g)}\chi_V(g) \qquad (\text{by } (13.118.1))$$
$$= \operatorname{sgn}(g)\,\chi_V(g).$$

Hence, every $g \in \mathfrak{S}_n$ satisfies $\left(\widetilde{\omega}_n(\chi_V)\right)(g) = \operatorname{sgn}(g)\,\chi_V(g) = \chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V}(g)$. In other words, $\widetilde{\omega}_n(\chi_V) = \chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V}$.

Forget that we fixed V. We thus have proven that $\widetilde{\omega}_n(\chi_V) = \chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V}$ for every finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V. In particular, for every irreducible $\mathbb{C}\mathfrak{S}_n$-module V, we have $\widetilde{\omega}_n(\chi_V) = \chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V} \in R(\mathfrak{S}_n)$. Since the χ_V span $R(\mathfrak{S}_n)$ as a $\mathbb{Z}$-module as V ranges through (a set of representatives of the isomorphism classes of) the irreducible $\mathbb{C}\mathfrak{S}_n$-modules V, this entails that the involution $\widetilde{\omega}_n$ preserves the $\mathbb{Z}$-lattice $R(\mathfrak{S}_n)$. Since $\widetilde{\omega}_n$ is the involution on class functions $f : \mathfrak{S}_n \to \mathbb{C}$ sending $f \mapsto \operatorname{sgn}_{\mathfrak{S}_n} * f$, this rewrites as follows:

[877] This is because every $g \in G$ satisfies

$$\chi_{U_1 \otimes U_2}(g) = \operatorname{trace} \underbrace{\left(g : U_1 \otimes U_2 \to U_1 \otimes U_2\right)}_{\substack{=(g,g) : U_1 \otimes U_2 \to U_1 \otimes U_2 \\ \text{(by the definition of the inner tensor product)}}}$$
$$= \operatorname{trace} \underbrace{\left((g,g) : U_1 \otimes U_2 \to U_1 \otimes U_2\right)}_{=(g : U_1 \to U_1) \otimes (g : U_2 \to U_2)} = \operatorname{trace}\left((g : U_1 \to U_1) \otimes (g : U_2 \to U_2)\right)$$
$$= \underbrace{\operatorname{trace}(g : U_1 \to U_1)}_{=\chi_{U_1}(g)} \cdot \underbrace{\operatorname{trace}(g : U_2 \to U_2)}_{=\chi_{U_2}(g)} = \chi_{U_1}(g) \cdot \chi_{U_2}(g).$$

[878] This is because multiplying a scalar by $\operatorname{sgn}(g)$ twice (for fixed $g \in \mathfrak{S}_n$) does nothing (since $(\operatorname{sgn}(g))^2 = 1$).

The involution on class functions $f : \mathfrak{S}_n \to \mathbb{C}$ sending $f \mapsto \operatorname{sgn}_{\mathfrak{S}_n} * f$ preserves the $\mathbb{Z}$-lattice $R(\mathfrak{S}_n)$. This proves one claim of Theorem 4.4.1(b).

Recall that the involution $\widetilde{\omega}_n$ preserves the $\mathbb{Z}$-lattice $R(\mathfrak{S}_n)$. Thus, $\widetilde{\omega}_n$ restricts to a $\mathbb{Z}$-linear involution $R(\mathfrak{S}_n) \to R(\mathfrak{S}_n)$. Denote this involution by $\widetilde{\omega}'_n$. It clearly satisfies

$$\widetilde{\omega}'_n(f) = \widetilde{\omega}_n(f) \qquad (\text{by the definition of } \widetilde{\omega}'_n) \tag{13.118.2}$$
$$= \operatorname{sgn}_{\mathfrak{S}_n} * f \qquad \text{for all } f \in R(\mathfrak{S}_n). \tag{13.118.3}$$

Step 3: The involution $\widetilde{\omega}_{\mathbb{Z}}$.

Now, forget that we fixed n. We thus have constructed a $\mathbb{Z}$-linear involution $\widetilde{\omega}'_n : R(\mathfrak{S}_n) \to R(\mathfrak{S}_n)$ for every $n \geq 0$. The direct sum of these involutions over all $n \geq 0$ is a graded $\mathbb{Z}$-linear involution $\bigoplus_{n\geq 0} \widetilde{\omega}'_n : \bigoplus_{n\geq 0} R(\mathfrak{S}_n) \to \bigoplus_{n\geq 0} R(\mathfrak{S}_n)$. Denote this involution $\bigoplus_{n\geq 0} \widetilde{\omega}'_n$ by $\widetilde{\omega}_{\mathbb{Z}}$. Then, $\widetilde{\omega}_{\mathbb{Z}}$ is a graded $\mathbb{Z}$-linear involution $A(\mathfrak{S}) \to A(\mathfrak{S})$ (since $\bigoplus_{n\geq 0} R(\mathfrak{S}_n) = A(\mathfrak{S})$), and is precisely the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b).

We have $\widetilde{\omega}_{\mathbb{Z}} = \bigoplus_{n\geq 0} \widetilde{\omega}'_n$. Hence, for every $n \in \mathbb{N}$ and $f \in R_{\mathbb{C}}(\mathfrak{S}_n)$, we have

$$\widetilde{\omega}_{\mathbb{Z}}(f) = \widetilde{\omega}'_n(f) = \widetilde{\omega}_n(f) \qquad (\text{since } \widetilde{\omega}'_n \text{ is defined as a restriction of } \widetilde{\omega}_n) \tag{13.118.4}$$
$$= \operatorname{sgn}_{\mathfrak{S}_n} * f. \tag{13.118.5}$$

For every $n \in \mathbb{N}$ and every finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V, we have

$$\widetilde{\omega}_{\mathbb{Z}}(\chi_V) = \widetilde{\omega}_n(\chi_V) \qquad (\text{by (13.118.4), applied to } f = \chi_V)$$
$$= \chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V}. \tag{13.118.6}$$

In other words, the involution $\widetilde{\omega}_{\mathbb{Z}}$ sends χ_V to $\chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V}$ for every $n \in \mathbb{N}$ and every finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V. In other words, the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b) sends χ_V to $\chi_{\operatorname{sgn}_{\mathfrak{S}_n} \otimes V}$ for every $n \in \mathbb{N}$ and every finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V (since $\widetilde{\omega}_{\mathbb{Z}}$ is precisely the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b)). This proves one of the claims of Exercise 4.4.4.

Step 4: Properties of $\widetilde{\omega}_{\mathbb{Z}}$.

We are now going to prove that $\operatorname{ch} \circ \widetilde{\omega}_{\mathbb{Z}} = \omega \circ \operatorname{ch}$ as maps $A(\mathfrak{S}) \to \Lambda$.

Indeed, let λ be a partition. Let $n = |\lambda|$. Then, $\lambda \in \operatorname{Par}_n$. Theorem 4.4.1(a) yields $\operatorname{ch}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right) = h_\lambda$ and $\operatorname{ch}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}\right) = e_\lambda$. Since $\operatorname{ch}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right) = h_\lambda$, we have $\operatorname{ch}^{-1}(h_\lambda) = \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}$. Since $\operatorname{ch}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}\right) = e_\lambda$, we have $\operatorname{ch}^{-1}(e_\lambda) = \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}$.

On the other hand, $\omega(h_\lambda) = e_\lambda$ [879].

But it is easy to see that $\widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right) = \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}$. [880]

[879] This follows from the fact that ω is an algebra homomorphism and that $\omega(h_m) = e_m$ for every $m \in \mathbb{N}$.

[880] *Proof.* Let $g \in \mathfrak{S}_n$. We have $\widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right) = \operatorname{sgn}_{\mathfrak{S}_n} * \left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)$ (by (13.118.4), applied to $f = \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}$). Hence,

$$\left(\widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)\right)(g) = \left(\operatorname{sgn}_{\mathfrak{S}_n} * \left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)\right)(g) = \operatorname{sgn}(g) \cdot \left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)(g)$$

(by the definition of $\operatorname{sgn}_{\mathfrak{S}_n} * \left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)$). Since (by the definition of $\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}$) we have

$$\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)(g) = \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n: \\ kgk^{-1} \in \mathfrak{S}_\lambda}} \underbrace{\underline{1}_{\mathfrak{S}_\lambda}(kgk^{-1})}_{=1} = \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n: \\ kgk^{-1} \in \mathfrak{S}_\lambda}} 1,$$

this rewrites as

$$\left(\widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)\right)(g) = \operatorname{sgn}(g) \cdot \underbrace{\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)(g)}_{= \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n: \\ kgk^{-1} \in \mathfrak{S}_\lambda}} 1} = \operatorname{sgn}(g) \cdot \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n: \\ kgk^{-1} \in \mathfrak{S}_\lambda}} 1.$$

Now, comparing

$$\left(\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}\right)(h_\lambda) = \widetilde{\omega}_{\mathbb{Z}}\left(\underbrace{\operatorname{ch}^{-1}(h_\lambda)}_{=\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}}\right) = \widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right) = \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}$$

with

$$\left(\operatorname{ch}^{-1} \circ \omega\right)(h_\lambda) = \operatorname{ch}^{-1}\left(\underbrace{\omega(h_\lambda)}_{=e_\lambda}\right) = \operatorname{ch}^{-1}(e_\lambda) = \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda},$$

we obtain $\left(\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}\right)(h_\lambda) = \left(\operatorname{ch}^{-1} \circ \omega\right)(h_\lambda)$.

So we have shown that $\left(\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}\right)(h_\lambda) = \left(\operatorname{ch}^{-1} \circ \omega\right)(h_\lambda)$ for every partition λ. Thus, $\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1} = \operatorname{ch}^{-1} \circ \omega$ (since the h_λ form a $\mathbb{Z}$-module basis of Λ). Hence, $\operatorname{ch}^{-1} \circ \omega = \widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}$ so that $\operatorname{ch}^{-1} \circ \omega \circ \operatorname{ch} = \widetilde{\omega}_{\mathbb{Z}}$ and $\omega \circ \operatorname{ch} = \operatorname{ch} \circ \widetilde{\omega}_{\mathbb{Z}}$.

We thus have $\operatorname{ch} \circ \widetilde{\omega}_{\mathbb{Z}} = \omega \circ \operatorname{ch}$ as maps $A(\mathfrak{S}) \to \Lambda$. In other words, the map $\widetilde{\omega}_{\mathbb{Z}}$ corresponds under ch to the involution ω on Λ. In other words, the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b) corresponds under ch to the involution ω on Λ (since $\widetilde{\omega}_{\mathbb{Z}}$ is precisely the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b)). This completes the proof of Theorem 4.4.1(b).

Step 5: The structure-preserving properties of $\widetilde{\omega}_{\mathbb{Z}}$.

Now, it only remains to show that the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b) is a nontrivial PSH-automorphism of $A(\mathfrak{S})$.

Recall that ch is a PSH-isomorphism. Hence, its inverse ch^{-1} also is a PSH-isomorphism.

Proposition 2.4.3(f) shows that $\omega : \Lambda \to \Lambda$ is a Hopf automorphism. Moreover, the map ω is clearly graded. Let Σ denote the PSH-basis $\{s_\lambda \mid \lambda \in \operatorname{Par}\}$ of Λ. Then, ω restricts to a bijection $\Sigma \to \Sigma$ [881]. As a consequence, $\omega(\Sigma) \subset \Sigma$, so that $\omega(\mathbb{N}\Sigma) = \mathbb{N}\underbrace{\omega(\Sigma)}_{\subset\Sigma} \subset \mathbb{N}\Sigma$. Hence, ω is a PSH-morphism $\Lambda \to \Lambda$ (since ω is a graded Hopf algebra morphism), and thus a PSH-isomorphism $\Lambda \to \Lambda$ (since ω is an isomorphism and restricts to a bijection $\Sigma \to \Sigma$).

Now, $\operatorname{ch}^{-1} \circ \omega \circ \operatorname{ch}$ is the composition of three PSH-isomorphisms (since ch^{-1}, ω and ch are PSH-isomorphisms), therefore a PSH-isomorphism itself. In other words, $\widetilde{\omega}_{\mathbb{Z}}$ is a PSH-isomorphism (because $\widetilde{\omega}_{\mathbb{Z}} = \operatorname{ch}^{-1} \circ \omega \circ \operatorname{ch}$). Thus, $\widetilde{\omega}_{\mathbb{Z}}$ is a PSH-automorphism.

Since $\omega(h_2) = e_2 \neq h_2$, we have $\omega \neq \operatorname{id}$ and therefore $\widetilde{\omega}_{\mathbb{Z}} \neq \operatorname{id}$ (since $\widetilde{\omega}_{\mathbb{Z}} = \operatorname{ch}^{-1} \circ \omega \circ \operatorname{ch}$). In other words, $\widetilde{\omega}_{\mathbb{Z}}$ is nontrivial.

So we know that $\widetilde{\omega}_{\mathbb{Z}}$ is a nontrivial PSH-automorphism of $A(\mathfrak{S})$. In other words, the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b) is a nontrivial PSH-automorphism of $A(\mathfrak{S})$ (since $\widetilde{\omega}_{\mathbb{Z}}$ is precisely the involution on $A(\mathfrak{S})$ defined in Theorem 4.4.1(b)). This completes the solution of Exercise 4.4.4.

Remark. There are some alternative ways to solve parts of this exercise.

For example, in order to prove that $\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1} = \operatorname{ch}^{-1} \circ \omega$, we showed that $\left(\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}\right)(h_\lambda) = \left(\operatorname{ch}^{-1} \circ \omega\right)(h_\lambda)$ for every partition λ. Instead of doing this, it is possible to prove that $\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1} = \operatorname{ch}^{-1} \circ \omega$ by showing that

Compared with

$$\begin{aligned}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}\right)(g) &= \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n : \\ kgk^{-1} \in \mathfrak{S}_\lambda}} \underbrace{\operatorname{sgn}_{\mathfrak{S}_\lambda}\left(kgk^{-1}\right)}_{=\operatorname{sgn}\left(kgk^{-1}\right)} \qquad \left(\text{by the definition of } \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}\right) \\ &= \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n : \\ kgk^{-1} \in \mathfrak{S}_\lambda}} \underbrace{\operatorname{sgn}\left(kgk^{-1}\right)}_{\substack{=\operatorname{sgn}(k) \cdot \operatorname{sgn}(g) \cdot (\operatorname{sgn}(k))^{-1} \\ =\operatorname{sgn}(g) = \operatorname{sgn}(g) \cdot 1}} = \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n : \\ kgk^{-1} \in \mathfrak{S}_\lambda}} \operatorname{sgn}(g) \cdot 1 = \operatorname{sgn}(g) \cdot \frac{1}{|\mathfrak{S}_\lambda|} \sum_{\substack{k \in \mathfrak{S}_n : \\ kgk^{-1} \in \mathfrak{S}_\lambda}} 1,\end{aligned}$$

this yields $\left(\widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)\right)(g) = \left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}\right)(g)$.

Now, forget that we fixed g. We thus have shown that $\left(\widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right)\right)(g) = \left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}\right)(g)$ for every $g \in \mathfrak{S}_n$. In other words, $\widetilde{\omega}_{\mathbb{Z}}\left(\operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \underline{1}_{\mathfrak{S}_\lambda}\right) = \operatorname{Ind}_{\mathfrak{S}_\lambda}^{\mathfrak{S}_n} \operatorname{sgn}_{\mathfrak{S}_\lambda}$, qed.

[881] This follows from Lemma 13.99.3.

$\left(\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}\right)(p_\lambda) = \left(\operatorname{ch}^{-1} \circ \omega\right)(p_\lambda)$ for every partition λ. This, however, requires a little technicality (the p_λ do not span Λ as a $\mathbb{Z}$-module, only as a $\mathbb{Q}$-module).

We showed that $\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1} = \operatorname{ch}^{-1} \circ \omega$ and used this to conclude that $\widetilde{\omega}_{\mathbb{Z}}$ is a PSH-automorphism of $A(\mathfrak{S})$. An alternative argument proceeds the other way round: The map $\widetilde{\omega}_{\mathbb{Z}}$ is $\mathbb{Z}$-linear and graded and is easily seen to be self-adjoint with respect to the inner product on $A(\mathfrak{S})$. It also is a coalgebra morphism, as $\operatorname{Res}^{\mathfrak{S}_n}_{\mathfrak{S}_i \times \mathfrak{S}_j} \omega_n(f) = (\omega_i \otimes \omega_j)\left(\operatorname{Res}^{\mathfrak{S}_n}_{\mathfrak{S}_i \times \mathfrak{S}_j} f\right)$ for all $n = i + j$ and all $f \in R(\mathfrak{S}_n)$. Hence, this map $\widetilde{\omega}_{\mathbb{Z}}$ also is an algebra morphism (since it is self-adjoint, and $A(\mathfrak{S})$ is self-dual), hence a bialgebra morphism and thus a Hopf morphism (by Corollary 1.4.27). It also sends irreducible characters to irreducible characters (by (13.118.6)), and thus restricts to a bijection $\{\chi^\lambda\} \to \{\chi^\lambda\}$. Hence, $\widetilde{\omega}_{\mathbb{Z}}$ is a PSH-automorphism of $A(\mathfrak{S})$. Every $n \geq 0$ satisfies

$$\begin{aligned}
\left(\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}\right)(h_n) &= \widetilde{\omega}_{\mathbb{Z}}\left(\underbrace{\operatorname{ch}^{-1}(h_n)}_{=\underline{1}_{\mathfrak{S}_n}}\right) = \widetilde{\omega}_{\mathbb{Z}}\left(\underline{1}_{\mathfrak{S}_n}\right) = \omega_n\left(\underline{1}_{\mathfrak{S}_n}\right) = \operatorname{sgn}_{\mathfrak{S}_n} = \operatorname{ch}^{-1}(e_n) \\
&= \operatorname{ch}^{-1}(\omega(h_n)) \qquad \text{(since Proposition 2.4.3(b) yields } e_n = \omega(h_n)) \\
&= \left(\operatorname{ch}^{-1} \circ \omega\right)(h_n).
\end{aligned}$$

Since $\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1}$ and $\operatorname{ch}^{-1} \circ \omega$ are algebra morphisms whereas the h_n generate Λ, this yields $\widetilde{\omega}_{\mathbb{Z}} \circ \operatorname{ch}^{-1} = \operatorname{ch}^{-1} \circ \omega$.

13.119. **Solution to Exercise 4.4.5.** *Solution to Exercise 4.4.5.* It is known that two permutations in $\mathfrak{S}_n$ have the same cycle type if and only if they are conjugate. In other words, if g and h are two permutations in $\mathfrak{S}_n$, then we have the following logical equivalence:

$$(g \text{ and } h \text{ have the same cycle type}) \iff (g \text{ and } h \text{ are conjugate}). \tag{13.119.1}$$

(a) Let $f \in R_{\mathbb{C}}(\mathfrak{S}_n)$.

If $\sigma \in \mathfrak{S}_n$, then the cycle type of σ is a partition of n. In other words, we have $\operatorname{type}\sigma \in \operatorname{Par}_n$ for each $\sigma \in \mathfrak{S}_n$ (since $\operatorname{type}\sigma$ denotes the cycle type of σ, while Par_n denotes the set of all partitions of n).

For each partition λ, we define a positive integer z_λ as in Proposition 2.5.15.

Recall the following fact from finite group theory:

> *Claim 1:* Let G be any finite group. Let $g \in G$ be any element. Let C_g denote the conjugacy class of g. Let Z_g denote the centralizer of g. Then,

$$|C_g| = \frac{|G|}{|Z_g|}. \tag{13.119.2}$$

Applying Claim 1 to the symmetric group $\mathfrak{S}_n$, we quickly arrive at the following:

> *Claim 2:* For each $\lambda \in \operatorname{Par}_n$, we have
> $$(\text{the number of all } \sigma \in \mathfrak{S}_n \text{ satisfying } \operatorname{type}\sigma = \lambda) = \frac{n!}{z_\lambda}.$$

[*Proof of Claim 2:* Let $\lambda \in \operatorname{Par}_n$. Thus, λ is a partition of n. Hence, there exists a permutation in $\mathfrak{S}_n$ that has cycle type λ. [882] Choose such a permutation, and denote it by g.

Let C_g denote the conjugacy class of g in $\mathfrak{S}_n$. Let Z_g denote the centralizer of g in $\mathfrak{S}_n$.

We have $|\lambda| = n$ (since λ is a partition of n). Hence, from Remark 2.5.16, we know that z_λ is the size of the $\mathfrak{S}_n$-centralizer subgroup for a permutation having cycle type λ. Thus, z_λ is the size of the $\mathfrak{S}_n$-centralizer subgroup of g (since $g \in \mathfrak{S}_n$ is a permutation having cycle type λ). In other words, $z_\lambda = |Z_g|$ (since Z_g is the $\mathfrak{S}_n$-centralizer subgroup of g).

[882] Indeed, we can obtain such a permutation as follows: Let $\ell = \ell(\lambda)$, so that $\lambda_1 + \lambda_2 + \cdots + \lambda_\ell = |\lambda| = n$. Partition the n-element set $\{1, 2, \ldots, n\}$ into ℓ disjoint subsets $K_1, K_2, \ldots, K_\ell$ of sizes $\lambda_1, \lambda_2, \ldots, \lambda_\ell$, respectively. For each $i \in \{1, 2, \ldots, \ell\}$, pick an arbitrary permutation in $\mathfrak{S}_n$ that fixes each element of $\{1, 2, \ldots, n\} \setminus K_i$ while consisting of a single λ_i-cycle on the set K_i. (Thus, c_i cycles through the λ_i elements of K_i in some order while leaving all remaining elements of $\{1, 2, \ldots, n\}$ unchanged.) Then, the composition $c_1 c_2 \cdots c_\ell$ of these cycles is a permutation in $\mathfrak{S}_n$ that has cycle type λ.

On the other hand, the definition of C_g yields

$$\begin{aligned} C_g &= (\text{the conjugacy class of } g) \\ &= \left\{ h \in \mathfrak{S}_n \mid \underbrace{h \text{ is conjugate to } g}_{\substack{\iff (g \text{ and } h \text{ are conjugate}) \\ \iff (g \text{ and } h \text{ have the same cycle type}) \\ (\text{by the equivalence (13.119.1)})}} \right\} = \left\{ h \in \mathfrak{S}_n \mid \underbrace{g \text{ and } h \text{ have the same cycle type}}_{\substack{\iff (h \text{ has cycle type } \lambda) \\ (\text{since } g \text{ has cycle type } \lambda)}} \right\} \\ &= \left\{ h \in \mathfrak{S}_n \mid \underbrace{h \text{ has cycle type } \lambda}_{\iff (\operatorname{type} h = \lambda)} \right\} = \{ h \in \mathfrak{S}_n \mid \operatorname{type} h = \lambda \} = \{ \sigma \in \mathfrak{S}_n \mid \operatorname{type} \sigma = \lambda \} \end{aligned}$$

(here, we have renamed the index h as σ). Thus,

$$|C_g| = |\{ \sigma \in \mathfrak{S}_n \mid \operatorname{type} \sigma = \lambda \}| = (\text{the number of all } \sigma \in \mathfrak{S}_n \text{ satisfying } \operatorname{type} \sigma = \lambda).$$

Comparing this with

$$\begin{aligned} |C_g| &= \frac{|\mathfrak{S}_n|}{|Z_g|} && (\text{by Claim 1, applied to } G = \mathfrak{S}_n) \\ &= \frac{n!}{z_\lambda} && (\text{since } |\mathfrak{S}_n| = n! \text{ and } |Z_g| = z_\lambda), \end{aligned}$$

we obtain

$$(\text{the number of all } \sigma \in \mathfrak{S}_n \text{ satisfying } \operatorname{type} \sigma = \lambda) = \frac{n!}{z_\lambda}.$$

This proves Claim 2.]

For each partition λ of n, there exists a permutation in $\mathfrak{S}_n$ that has cycle type λ. Choose such a permutation, and denote it by g_λ. Every $h \in \mathfrak{S}_n$ satisfies

$$f(h) = f(g_{\operatorname{type} h}). \tag{13.119.3}$$

[*Proof of* (13.119.3)*:* Let $h \in \mathfrak{S}_n$. Hence, $\operatorname{type} h \in \operatorname{Par}_n$ (since $\operatorname{type} \sigma \in \operatorname{Par}_n$ for each $\sigma \in \mathfrak{S}_n$). Therefore, the permutation $g_{\operatorname{type} h} \in \mathfrak{S}_n$ is well-defined.

The definition of $\operatorname{type} h$ shows that the permutation h has cycle type $\operatorname{type} h$. On the other hand, the permutation $g_{\operatorname{type} h}$ also has cycle type $\operatorname{type} h$ (by the definition of $g_{\operatorname{type} h}$). Hence, the two permutations $g_{\operatorname{type} h}$ and h in $\mathfrak{S}_n$ have the same cycle type (namely, $\operatorname{type} h$). But (13.119.1) (applied to $g_{\operatorname{type} h}$ instead of g) shows that we have the equivalence

$$(g_{\operatorname{type} h} \text{ and } h \text{ have the same cycle type}) \iff (g_{\operatorname{type} h} \text{ and } h \text{ are conjugate}).$$

Hence, $g_{\operatorname{type} h}$ and h are conjugate (since $g_{\operatorname{type} h}$ and h have the same cycle type).

But we have $f \in R_{\mathbb{C}}(\mathfrak{S}_n)$. In other words, f is a class function of $\mathfrak{S}_n$ (since $R_{\mathbb{C}}(\mathfrak{S}_n)$ is the space of all class functions $\mathfrak{S}_n \to \mathbb{C}$ of $\mathfrak{S}_n$). In other words, f is a map $\mathfrak{S}_n \to \mathbb{C}$ that is constant on $\mathfrak{S}_n$-conjugacy classes (because this is what it means to be a class function of $\mathfrak{S}_n$). Thus, in particular, f is constant on $\mathfrak{S}_n$-conjugacy classes. In other words, if x and y are two conjugate elements of $\mathfrak{S}_n$, then $f(x) = f(y)$. Applying this to $x = g_{\operatorname{type} h}$ and $y = h$, we obtain $f(g_{\operatorname{type} h}) = f(h)$ (since the elements $g_{\operatorname{type} h}$ and h of $\mathfrak{S}_n$ are conjugate). This proves (13.119.3).]

Recall that $\operatorname{type}\sigma \in \operatorname{Par}_n$ for each $\sigma \in \mathfrak{S}_n$. Thus, we can split the sum $\sum_{\sigma\in\mathfrak{S}_n} f(\sigma)\, p_{\operatorname{type}\sigma}$ according to the value of $\operatorname{type}\sigma$. We thus obtain

$$\begin{aligned}
\underbrace{\sum_{\sigma\in\mathfrak{S}_n}}_{\substack{=\sum_{\lambda\in\operatorname{Par}_n}\ \sum_{\substack{\sigma\in\mathfrak{S}_n;\\ \operatorname{type}\sigma=\lambda}}\\ \text{(since } \operatorname{type}\sigma\in\operatorname{Par}_n\\ \text{for each } \sigma\in\mathfrak{S}_n)}} f(\sigma)\, p_{\operatorname{type}\sigma} &= \sum_{\lambda\in\operatorname{Par}_n}\ \sum_{\substack{\sigma\in\mathfrak{S}_n;\\ \operatorname{type}\sigma=\lambda}} \underbrace{f(\sigma)}_{\substack{=f(g_{\operatorname{type}\sigma})\\ \text{(by (13.119.3), applied to } h=\sigma)}} p_{\operatorname{type}\sigma} \\
&= \sum_{\lambda\in\operatorname{Par}_n}\ \sum_{\substack{\sigma\in\mathfrak{S}_n;\\ \operatorname{type}\sigma=\lambda}} \underbrace{f(g_{\operatorname{type}\sigma})}_{\substack{=f(g_\lambda)\\ \text{(since } \operatorname{type}\sigma=\lambda)}} \underbrace{p_{\operatorname{type}\sigma}}_{\substack{=p_\lambda\\ \text{(since } \operatorname{type}\sigma=\lambda)}} \\
&= \sum_{\lambda\in\operatorname{Par}_n} \underbrace{\sum_{\substack{\sigma\in\mathfrak{S}_n;\\ \operatorname{type}\sigma=\lambda}} f(g_\lambda)\, p_\lambda}_{=(\text{the number of all } \sigma\in\mathfrak{S}_n \text{ satisfying } \operatorname{type}\sigma=\lambda)\cdot f(g_\lambda) p_\lambda} \\
&= \sum_{\lambda\in\operatorname{Par}_n} \underbrace{(\text{the number of all } \sigma \in \mathfrak{S}_n \text{ satisfying } \operatorname{type}\sigma = \lambda)}_{\substack{=\frac{n!}{z_\lambda}\\ \text{(by Claim 2)}}} \cdot f(g_\lambda)\, p_\lambda \\
&= \sum_{\lambda\in\operatorname{Par}_n} \frac{n!}{z_\lambda} \cdot f(g_\lambda)\, p_\lambda .
\end{aligned}$$

Multiplying both sides of this equality by $\dfrac{1}{n!}$, we obtain

$$\begin{aligned}
\frac{1}{n!} \sum_{\sigma\in\mathfrak{S}_n} f(\sigma)\, p_{\operatorname{type}\sigma} = \frac{1}{n!} \cdot \sum_{\lambda\in\operatorname{Par}_n} \frac{n!}{z_\lambda} \cdot f(g_\lambda)\, p_\lambda &= \sum_{\lambda\in\operatorname{Par}_n} \underbrace{\frac{1}{n!} \cdot \frac{n!}{z_\lambda} \cdot f(g_\lambda)\, p_\lambda}_{=f(g_\lambda)\cdot \frac{p_\lambda}{z_\lambda}} \\
&= \sum_{\lambda\in\operatorname{Par}_n} f(g_\lambda) \cdot \frac{p_\lambda}{z_\lambda}. \qquad (13.119.4)
\end{aligned}$$

We shall now show that

$$f = \sum_{\lambda\in\operatorname{Par}_n} f(g_\lambda)\, \underline{1}_\lambda. \qquad (13.119.5)$$

[*Proof of* (13.119.5)*:* Let $h \in \mathfrak{S}_n$. Then, $\operatorname{type} h$ is the cycle type of h (by the definition of $\operatorname{type} h$). In other words, h has cycle type $\operatorname{type} h$.

Recall that $\operatorname{type}\sigma \in \operatorname{Par}_n$ for each $\sigma \in \mathfrak{S}_n$. Applying this to $\sigma = h$, we obtain $\operatorname{type} h \in \operatorname{Par}_n$.

For each partition $\lambda \in \operatorname{Par}_n$, we have

$$\underline{1}_\lambda(h) = \begin{cases} 1, & \text{if } h \text{ has cycle type } \lambda; \\ 0, & \text{otherwise} \end{cases} \qquad (13.119.6)$$

(since $\underline{1}_\lambda$ was defined as the characteristic function for the $\mathfrak{S}_n$-conjugacy class of permutations of cycle type λ). Applying this to $\lambda = \operatorname{type} h$, we obtain

$$\underline{1}_{\operatorname{type} h}(h) = \begin{cases} 1, & \text{if } h \text{ has cycle type } \operatorname{type} h; \\ 0, & \text{otherwise} \end{cases} = 1 \qquad (13.119.7)$$

(since h has cycle type $\operatorname{type} h$). On the other hand, if $\lambda \in \operatorname{Par}_n$ is a partition such that $\lambda \neq \operatorname{type} h$, then h does not have cycle type λ [883], and therefore we have

$$\begin{aligned} \underline{1}_\lambda(h) &= \begin{cases} 1, & \text{if } h \text{ has cycle type } \lambda; \\ 0, & \text{otherwise} \end{cases} \qquad (\text{by } (13.119.6)) \\ &= 0 \qquad (\text{since } h \text{ does not have cycle type } \lambda). \end{aligned} \tag{13.119.8}$$

Now,

$$\begin{aligned} \left(\sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \underline{1}_\lambda\right)(h) &= \sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \underline{1}_\lambda(h) \\ &= f\left(g_{\operatorname{type} h}\right) \underbrace{\underline{1}_{\operatorname{type} h}(h)}_{\substack{=1 \\ (\text{by } (13.119.7))}} + \sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \lambda \neq \operatorname{type} h}} f(g_\lambda) \underbrace{\underline{1}_\lambda(h)}_{\substack{=0 \\ (\text{by } (13.119.8))}} \\ &\qquad \left(\begin{array}{c} \text{here, we have split off the addend for } \lambda = \operatorname{type} h \text{ from the sum,} \\ \text{since } \operatorname{type} h \in \operatorname{Par}_n \end{array}\right) \\ &= f\left(g_{\operatorname{type} h}\right) + \underbrace{\sum_{\substack{\lambda \in \operatorname{Par}_n; \\ \lambda \neq \operatorname{type} h}} f(g_\lambda) 0}_{=0} = f\left(g_{\operatorname{type} h}\right) = f(h) \qquad (\text{by } (13.119.3)). \end{aligned}$$

Forget that we fixed h. We thus have shown that $\left(\sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \underline{1}_\lambda\right)(h) = f(h)$ for each $h \in \mathfrak{S}_n$. In other words, $\sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \underline{1}_\lambda = f$ (since both $\sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \underline{1}_\lambda$ and f are maps from $\mathfrak{S}_n$ to $\mathbb{C}$). This proves (13.119.5).]

One of the claims of Theorem 4.4.1(a) is the formula

$$\operatorname{ch}\left(\underline{1}_\lambda\right) = \frac{p_\lambda}{z_\lambda} \qquad \text{for every } \lambda \in \operatorname{Par}_n. \tag{13.119.9}$$

Now, applying the map $\operatorname{ch} : A_{\mathbb{C}} \to \Lambda_{\mathbb{C}}$ to both sides of the equality (13.119.5), we find

$$\begin{aligned} \operatorname{ch}(f) &= \operatorname{ch}\left(\sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \underline{1}_\lambda\right) = \sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \underbrace{\operatorname{ch}\left(\underline{1}_\lambda\right)}_{\substack{= \frac{p_\lambda}{z_\lambda} \\ (\text{by } (13.119.9))}} \\ &\qquad (\text{since the map } \operatorname{ch} : A_{\mathbb{C}} \to \Lambda_{\mathbb{C}} \text{ is } \mathbb{C}\text{-linear}) \\ &= \sum_{\lambda \in \operatorname{Par}_n} f(g_\lambda) \cdot \frac{p_\lambda}{z_\lambda} = \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} f(\sigma) p_{\operatorname{type} \sigma} \end{aligned}$$

(by (13.119.4)). This solves Exercise 4.4.5(a).

(b) It is easy to see that every $k \in \mathfrak{S}_n$ and $\sigma \in \mathfrak{S}_n$ satisfy

$$p_{\operatorname{type} \sigma} = p_{\operatorname{type}(k\sigma k^{-1})}. \tag{13.119.10}$$

[*Proof of* (13.119.10)*:* Let $k \in \mathfrak{S}_n$ and $\sigma \in \mathfrak{S}_n$. Then, (13.119.1) (applied to $g = \sigma$ and $h = k\sigma k^{-1}$) yields the equivalence

$$\left(\sigma \text{ and } k\sigma k^{-1} \text{ have the same cycle type}\right) \iff \left(\sigma \text{ and } k\sigma k^{-1} \text{ are conjugate}\right).$$

Hence, σ and $k\sigma k^{-1}$ have the same cycle type (since σ and $k\sigma k^{-1}$ are conjugate). In other words, $\operatorname{type} \sigma = \operatorname{type}\left(k\sigma k^{-1}\right)$. Hence, $p_{\operatorname{type} \sigma} = p_{\operatorname{type}(k\sigma k^{-1})}$. This proves (13.119.10).]

[883] *Proof.* Assume the contrary. Thus, h has cycle type λ. In other words, the cycle type of h is λ. In other words, $\operatorname{type} h$ is λ (since $\operatorname{type} h$ is the cycle type of h). In other words, $\operatorname{type} h = \lambda$. But this contradicts $\lambda \neq \operatorname{type} h$. This contradiction shows that our assumption was false. Qed.

Let $f \in R_{\mathbb{C}}(H)$. Applying (4.1.4) to $G = \mathfrak{S}_n$, we obtain

$$\left(\operatorname{Ind}_H^{\mathfrak{S}_n} f\right)(g) = \frac{1}{|H|} \sum_{\substack{k \in \mathfrak{S}_n: \\ kgk^{-1} \in H}} f\left(kgk^{-1}\right) \tag{13.119.11}$$

for all $g \in \mathfrak{S}_n$. Furthermore, Exercise 4.1.1(a) (applied to $G = \mathfrak{S}_n$) shows that $\operatorname{Ind}_H^{\mathfrak{S}_n} f$ is a class function on $\mathfrak{S}_n$, hence belongs to $R_{\mathbb{C}}(\mathfrak{S}_n)$. Hence, Exercise 4.4.5(a) (applied to $\operatorname{Ind}_H^{\mathfrak{S}_n} f$ instead of f) yields

$$\begin{aligned}
\operatorname{ch}\left(\operatorname{Ind}_H^{\mathfrak{S}_n} f\right) &= \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} \underbrace{\left(\operatorname{Ind}_H^{\mathfrak{S}_n} f\right)(\sigma)}_{\substack{= \frac{1}{|H|} \sum_{\substack{k \in \mathfrak{S}_n: \\ k\sigma k^{-1} \in H}} f\left(k\sigma k^{-1}\right) \\ \text{(by (13.119.11), applied to } g = \sigma)}} p_{\operatorname{type}\sigma} \\
&= \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} \frac{1}{|H|} \sum_{\substack{k \in \mathfrak{S}_n: \\ k\sigma k^{-1} \in H}} f\left(k\sigma k^{-1}\right) \underbrace{p_{\operatorname{type}\sigma}}_{\substack{= p_{\operatorname{type}(k\sigma k^{-1})} \\ \text{(by (13.119.10))}}} \\
&= \frac{1}{n!} \sum_{\sigma \in \mathfrak{S}_n} \frac{1}{|H|} \sum_{\substack{k \in \mathfrak{S}_n: \\ k\sigma k^{-1} \in H}} f\left(k\sigma k^{-1}\right) p_{\operatorname{type}(k\sigma k^{-1})} \\
&= \frac{1}{n!} \underbrace{\sum_{\sigma \in \mathfrak{S}_n} \sum_{\substack{k \in \mathfrak{S}_n: \\ k\sigma k^{-1} \in H}}}_{= \sum_{k \in \mathfrak{S}_n} \sum_{\substack{\sigma \in \mathfrak{S}_n: \\ k\sigma k^{-1} \in H}}} \frac{1}{|H|} f\left(k\sigma k^{-1}\right) p_{\operatorname{type}(k\sigma k^{-1})} \\
&= \frac{1}{n!} \sum_{k \in \mathfrak{S}_n} \underbrace{\sum_{\substack{\sigma \in \mathfrak{S}_n: \\ k\sigma k^{-1} \in H}} \frac{1}{|H|} f\left(k\sigma k^{-1}\right) p_{\operatorname{type}(k\sigma k^{-1})}}_{\substack{= \sum_{\substack{h \in \mathfrak{S}_n: \\ h \in H}} \frac{1}{|H|} f(h) p_{\operatorname{type}h} \\ \text{(here, we have substituted } h \text{ for } k\sigma k^{-1} \text{ in the sum,} \\ \text{since the map } \mathfrak{S}_n \to \mathfrak{S}_n,\ \sigma \mapsto k\sigma k^{-1} \text{ is a bijection)}}} \\
&= \frac{1}{n!} \sum_{k \in \mathfrak{S}_n} \underbrace{\sum_{\substack{h \in \mathfrak{S}_n: \\ h \in H}}}_{\substack{= \sum_{h \in H} \\ \text{(since } H \subset \mathfrak{S}_n)}} \frac{1}{|H|} f(h) p_{\operatorname{type}h} = \frac{1}{n!} \underbrace{\sum_{k \in \mathfrak{S}_n} \sum_{h \in H} \frac{1}{|H|} f(h) p_{\operatorname{type}h}}_{= |\mathfrak{S}_n| \cdot \sum_{h \in H} \frac{1}{|H|} f(h) p_{\operatorname{type}h}} \\
&= \frac{1}{n!} \cdot \underbrace{|\mathfrak{S}_n|}_{= n!} \cdot \sum_{h \in H} \frac{1}{|H|} f(h) p_{\operatorname{type}h} = \underbrace{\frac{1}{n!} \cdot n!}_{= 1} \cdot \sum_{h \in H} \frac{1}{|H|} f(h) p_{\operatorname{type}h} \\
&= \sum_{h \in H} \frac{1}{|H|} f(h) p_{\operatorname{type}h} = \frac{1}{|H|} \sum_{h \in H} f(h) p_{\operatorname{type}h}.
\end{aligned}$$

This solves Exercise 4.4.5(b).

13.120. **Solution to Exercise 4.4.6.** *Solution to Exercise 4.4.6.* We need an auxiliary observation first. If G is a finite group, then a class function $\chi \in R_{\mathbb{C}}(G)$ of G will be called *integral* if every $g \in G$ satisfies $\chi(g) \in \mathbb{Z}$. Then, if G and H are two groups and if ϕ and ψ are two integral class functions of G and H, respectively, then

$$\phi \otimes \psi \text{ is an integral class function of } G \times H. \tag{13.120.1}$$

(This is a consequence of the fact that $(\phi \otimes \psi)(g,h) = \phi(g)\psi(h)$ for all $(g,h) \in G \times H$.) Moreover, if H is a subgroup of a group G and if χ is an integral class function of H, then

$$\operatorname{Ind}_H^G \chi \text{ is an integral class function of } G. \tag{13.120.2}$$

(*Proof of* (13.120.2)*:* Let J be a system of coset representatives for $H \backslash G$, so that $G = \bigsqcup_{j \in J} Hj$. Then, Exercise 4.1.1(a) (applied to $f = \chi$) shows that $\operatorname{Ind}_H^G \chi$ is a class function on G. Also, Exercise 4.1.1(b) (applied to $f = \chi$) yields

$$\left(\operatorname{Ind}_H^G \chi\right)(g) = \sum_{\substack{j \in J: \\ jgj^{-1} \in H}} \underbrace{\chi\left(jgj^{-1}\right)}_{\substack{\in \mathbb{Z} \\ \text{(since } \chi \text{ is an integral} \\ \text{class function)}}} \in \mathbb{Z} \qquad \text{for all } g \in G.$$

In other words, $\operatorname{Ind}_H^G \chi$ is an integral class function on G. This proves (13.120.2).)

Now let $A = A(\mathfrak{S})$. For every $a \in A$, every $n \geq 0$ and every $g \in \mathfrak{S}_n$, we define $a(g)$ to mean the value at g of the n-th homogeneous component of a. Let $\widetilde{A}$ denote the subset of A formed by all $a \in A$ such that:

$$(\text{for every } n \geq 0 \text{ and every } g \in \mathfrak{S}_n, \text{ we have } a(g) \in \mathbb{Z}). \tag{13.120.3}$$

It is clear that $\widetilde{A}$ is a graded $\mathbb{Z}$-submodule of A and contains $1 = \underline{1}_{\mathfrak{S}_0}$.

We are now going to show that $\widetilde{A}$ is closed under multiplication. In order to do so, it is clearly enough to prove that if $a \in \widetilde{A}$ is homogeneous of degree n and $b \in \widetilde{A}$ is homogeneous of degree m, then $ab \in \widetilde{A}$. But this is now easy: Since $a \in \widetilde{A}$, we know that a is an integral class function on $\mathfrak{S}_n$. Similarly, b is an integral class function on $\mathfrak{S}_m$. Hence, (13.120.1) shows that $a \otimes b$ is an integral class function on $\mathfrak{S}_n \times \mathfrak{S}_m$. Thus, $\operatorname{Ind}_{\mathfrak{S}_n \times \mathfrak{S}_m}^{\mathfrak{S}_{n+m}} (a \otimes b)$ is an integral class function on $\mathfrak{S}_{n+m}$ (by (13.120.2)). In other words, ab is an integral class function on $\mathfrak{S}_{n+m}$ (since $ab = \operatorname{ind}_{n,m}^{n+m}(a \otimes b) = \operatorname{Ind}_{\mathfrak{S}_n \times \mathfrak{S}_m}^{\mathfrak{S}_{n+m}}(a \otimes b)$). In other words, $ab \in \widetilde{A}$. This proves that $\widetilde{A}$ is closed under multiplication. Hence, $\widetilde{A}$ is a subring of A (since $\widetilde{A}$ is a $\mathbb{Z}$-submodule of A and contains $1 = \underline{1}_{\mathfrak{S}_0}$). Thus, $\operatorname{ch}\left(\widetilde{A}\right)$ (where ch is defined as in Theorem 4.4.1) is a subring of Λ. For every $n \geq 1$, we have $\underline{1}_{\mathfrak{S}_n} \in \widetilde{A}$ (by the definitions), so that $\operatorname{ch}\left(\underline{1}_{\mathfrak{S}_n}\right) \in \operatorname{ch}\left(\widetilde{A}\right)$. Since $\operatorname{ch}\left(\underline{1}_{\mathfrak{S}_n}\right) = h_n$, this rewrites as $h_n \in \operatorname{ch}\left(\widetilde{A}\right)$. Thus, the subring $\operatorname{ch}\left(\widetilde{A}\right)$ of Λ contains h_n for all $n \geq 1$. Hence, $\operatorname{ch}\left(\widetilde{A}\right) = \Lambda$ (because the h_n generate Λ as a ring). Therefore, $\widetilde{A} = A$ (since ch is an isomorphism). If we recall how $\widetilde{A}$ was defined, we thus see that every $a \in A$ satisfies (13.120.3).

Now, fix $n \geq 0$ and $g \in \mathfrak{S}_n$ and a finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V. Then, $\chi_V \in R(\mathfrak{S}_n) \subset A$. Thus, (13.120.3) (which holds for every $a \in A$, as we now know) yields that $\chi_V(g) \in \mathbb{Z}$, which solves part (a) of the problem.

Note that a different way to solve part (a) would be by showing that Λ is contained in the $\mathbb{Z}$-submodule of $\Lambda_{\mathbb{Q}}$ spanned by the $\dfrac{p_\lambda}{z_\lambda}$ for all partitions λ. This yields (by taking preimages under ch) that A is contained in the $\mathbb{Z}$-submodule of $R_{\mathbb{C}}(\mathfrak{S})$ generated by the $\underline{1}_\lambda$. This way, we wouldn't have to show that $\widetilde{A}$ is closed under multiplication; instead, we would obtain $\widetilde{A} = A$ by noticing that all $\underline{1}_\lambda$ are integral class functions.

(b) This can be done using the Noether-Deuring theorem (in fact, it is easy to show that there are two $\mathbb{C}\mathfrak{S}_n$-modules U and U' defined over $\mathbb{Q}$ satisfying $U' \oplus V \cong U$, and then the Noether-Deuring theorem allows to "pull back" V to a $\mathbb{Q}\mathfrak{S}_n$-module as well, showing that V is also defined over $\mathbb{Q}$). We are omitting this argument because it is somewhat technical and not very enlightening. (The "right" approach, in my opinion, is to construct the required $\mathbb{Q}\mathfrak{S}_n$-module W explicitly; this is done, e.g., in [73, §7, between Proposition 1 and Lemma 3] or in [115, Corollaire 2.2.26]. Of course, this does not have much to do with what we are doing in our notes.)

13.121. **Solution to Exercise 4.4.8.** *Solution to Exercise 4.4.8.* (a) Let G be any group. If U_1 and U_2 are two $\mathbb{C}G$-modules, then the character $\chi_{U_1 \boxtimes U_2}$ of the inner tensor product $U_1 \boxtimes U_2$ of U_1 and U_2 is given by

$$\chi_{U_1 \boxtimes U_2}(g) = \chi_{U_1}(g) \chi_{U_2}(g) \qquad \text{for all } g \in G. \tag{13.121.1}$$

(This is just a restatement of (13.118.1) using our notation $U_1 \boxtimes U_2$ for what, in (13.118.1), was called $U_1 \otimes U_2$.)

Define a map $* : R_{\mathbb{C}}(G) \times R_{\mathbb{C}}(G) \to R_{\mathbb{C}}(G)$, which will be written in infix notation (that is, we will write $a * b$ instead of $*(a, b)$), by setting

$$(a * b)(g) = a(g) b(g) \qquad \text{for any } a \in R_{\mathbb{C}}(G), b \in R_{\mathbb{C}}(G) \text{ and } g \in G.$$

(This notation $a*b$ generalizes the notation $\operatorname{sgn}_{\mathfrak{S}_n} *f$ used in Theorem 4.4.1.) The map $*$ is clearly $\mathbb{C}$-bilinear.

Notice that

$$\chi_{U_1} * \chi_{U_2} = \chi_{U_1 \boxtimes U_2} \qquad \text{for any two } \mathbb{C}G\text{-modules } U_1 \text{ and } U_2 \tag{13.121.2}$$

[884]

Let $R_{\mathbb{Q}}(G)$ denote the set of class functions $G \to \mathbb{Q}$. This is clearly a subset of $R_{\mathbb{C}}(G)$. In general, it is not true that $R(G) \subset R_{\mathbb{Q}}(G)$, but we will see that this holds for $G = \mathfrak{S}_n$ for any $n \in \mathbb{N}$.

It is clear that $a * b \in R_{\mathbb{Q}}(G)$ for any $a \in R_{\mathbb{Q}}(G)$ and $b \in R_{\mathbb{Q}}(G)$.

Now, forget that we fixed G. We have thus introduced a map $* : R_{\mathbb{C}}(G) \times R_{\mathbb{C}}(G) \to R_{\mathbb{C}}(G)$ for every group G, and we have proved some properties of this map.

Let now $n \in \mathbb{N}$. Exercise 4.4.6(a) yields that $\chi_V(g) \in \mathbb{Z} \subset \mathbb{Q}$ for every $g \in \mathfrak{S}_n$ and every finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V. Hence, χ_V is a map from $\mathfrak{S}_n$ to $\mathbb{Q}$ for every finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V. In other words, $\chi_V \in R_{\mathbb{Q}}(\mathfrak{S}_n)$ for every finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module V. Thus, $R(\mathfrak{S}_n) \subset R_{\mathbb{Q}}(\mathfrak{S}_n)$ (since $R(\mathfrak{S}_n)$ is the $\mathbb{Z}$-module generated by the χ_V for V ranging over the irreducible $\mathbb{C}\mathfrak{S}_n$-modules).

Every element of $R_{\mathbb{Q}}(\mathfrak{S}_n)$ is a class function $\mathfrak{S}_n \to \mathbb{Q}$, and thus a $\mathbb{Q}$-linear combination of the $\underline{1}_\lambda$ for $\lambda \in \operatorname{Par}_n$ (because these functions $\underline{1}_\lambda$ are the indicator functions for the conjugacy classes of $\mathfrak{S}_n$). Thus, the $\mathbb{Q}$-module $R_{\mathbb{Q}}(\mathfrak{S}_n)$ is spanned by the $\underline{1}_\lambda$ for $\lambda \in \operatorname{Par}_n$.

As in Theorem 4.4.1, we extend the PSH-isomorphism $\operatorname{ch} : A \to \Lambda$ to a $\mathbb{C}$-Hopf algebra isomorphism $A_{\mathbb{C}} \to \Lambda_{\mathbb{C}}$; we shall denote the latter isomorphism by ch as well. Now, let us notice that

$$\operatorname{ch}(R_{\mathbb{Q}}(\mathfrak{S}_n)) \subset \Lambda_{\mathbb{Q}}. \tag{13.121.3}$$

[885] Furthermore,

$$\operatorname{ch}(a * b) = (\operatorname{ch} a) * (\operatorname{ch} b) \qquad \text{for any } a \in R_{\mathbb{Q}}(\mathfrak{S}_n) \text{ and } b \in R_{\mathbb{Q}}(\mathfrak{S}_n). \tag{13.121.4}$$

[886]

[884] *Proof of (13.121.2):* Let U_1 and U_2 be two $\mathbb{C}G$-modules. Then, every $g \in G$ satisfies

$$\begin{aligned}(\chi_{U_1} * \chi_{U_2})(g) &= \chi_{U_1}(g) \chi_{U_2}(g) && (\text{by the definition of } *)\\ &= \chi_{U_1 \boxtimes U_2}(g) && (\text{by (13.121.1)}).\end{aligned}$$

In other words, $\chi_{U_1} * \chi_{U_2} = \chi_{U_1 \boxtimes U_2}$. This proves (13.121.2).

[885] *Proof of (13.121.3):* It is clearly enough to show that $\operatorname{ch}(\underline{1}_\lambda) \in \Lambda_{\mathbb{Q}}$ for every $\lambda \in \operatorname{Par}_n$ (because the $\mathbb{Q}$-module $R_{\mathbb{Q}}(\mathfrak{S}_n)$ is spanned by the $\underline{1}_\lambda$ for $\lambda \in \operatorname{Par}_n$). But this follows from the fact that $\operatorname{ch}(\underline{1}_\lambda) = \frac{p_\lambda}{z_\lambda}$ for every $\lambda \in \operatorname{Par}_n$ (this is part of Theorem 4.4.1(a)). Thus, (13.121.3) is proven.

[886] *Proof of (13.121.4):* Let $a \in R_{\mathbb{Q}}(\mathfrak{S}_n)$ and $b \in R_{\mathbb{Q}}(\mathfrak{S}_n)$. The equality (13.121.4) is clearly $\mathbb{Q}$-linear in each of a and b. Hence, in proving this equality, we can WLOG assume that a and b are two of the functions $\underline{1}_\lambda$ for $\lambda \in \operatorname{Par}_n$ (because the $\mathbb{Q}$-module $R_{\mathbb{Q}}(\mathfrak{S}_n)$ is spanned by the $\underline{1}_\lambda$ for $\lambda \in \operatorname{Par}_n$). In other words, we can WLOG assume that $a = \underline{1}_\lambda$ and $b = \underline{1}_\mu$ for some $\lambda \in \operatorname{Par}_n$ and $\mu \in \operatorname{Par}_n$. Assume this, and consider these λ and μ.

Recall that $\underline{1}_\lambda$ is the indicator function for the set of all permutations in $\mathfrak{S}_n$ having cycle type λ, and that $\underline{1}_\mu$ is the indicator function for the set of all permutations in $\mathfrak{S}_n$ having cycle type μ. Hence, every $g \in \mathfrak{S}_n$ satisfies

$$\underline{1}_\lambda(g) \cdot \underline{1}_\mu(g) = \delta_{\lambda,\mu} \cdot \underline{1}_\lambda(g)$$

(because both sides of this equality vanish if g does not have cycle type λ, and also vanish if $\lambda \neq \mu$, but in the remaining case are both equal to 1). Thus, every $g \in \mathfrak{S}_n$ satisfies

$$\begin{aligned}\left(\underline{1}_\lambda * \underline{1}_\mu\right)(g) &= \underline{1}_\lambda(g) \cdot \underline{1}_\mu(g) && \left(\text{by the definition of } \underline{1}_\lambda * \underline{1}_\mu\right)\\ &= \delta_{\lambda,\mu} \cdot \underline{1}_\lambda(g) = (\delta_{\lambda,\mu}\underline{1}_\lambda)(g).\end{aligned}$$

Now, let U_1 and U_2 be two $\mathbb{C}\mathfrak{S}_n$-modules. Then, $\chi_{U_1} \in R(\mathfrak{S}_n) \subset R_{\mathbb{Q}}(\mathfrak{S}_n)$ and similarly $\chi_{U_2} \in R_{\mathbb{Q}}(\mathfrak{S}_n)$, so that (13.121.4) (applied to $a = \chi_{U_1}$ and $b = \chi_{U_2}$) yields $\operatorname{ch}(\chi_{U_1} * \chi_{U_2}) = \operatorname{ch}(\chi_{U_1}) * \operatorname{ch}(\chi_{U_2})$. Due to (13.121.2), this rewrites as $\operatorname{ch}(\chi_{U_1 \boxtimes U_2}) = \operatorname{ch}(\chi_{U_1}) * \operatorname{ch}(\chi_{U_2})$. This solves Exercise 4.4.8(a).

(c) Let us first recall that $p_\lambda * p_\mu = \delta_{\lambda,\mu} z_\lambda p_\lambda$ for any two partitions λ and μ. Thus, $p_\lambda * p_\mu = 0$ whenever $\lambda \neq \mu$. This yields, in particular, that $p_\lambda * p_\mu = 0$ whenever $|\lambda| \neq |\mu|$. In other words, for any two distinct integers n and m, we have $p_\lambda * p_\mu = 0$ for every $\lambda \in \operatorname{Par}_n$ and every $\mu \in \operatorname{Par}_m$. This yields that, for any two distinct integers n and m, we have $a * b = 0$ for every $a \in \Lambda_n$ and $b \in \Lambda_m$ (because a is a $\mathbb{Q}$-linear combination of the p_λ with $\lambda \in \operatorname{Par}_n$, whereas b is a $\mathbb{Q}$-linear combination of the p_μ with $\mu \in \operatorname{Par}_m$). In particular, for any two distinct integers n and m, we have

$$s_\mu * s_\nu = 0 \qquad \text{for any } \nu \in \operatorname{Par}_n \text{ and } \mu \in \operatorname{Par}_m$$

(because $s_\mu \in \Lambda_m$ and $s_\nu \in \Lambda_n$). In other words,

$$s_\mu * s_\nu = 0 \qquad \text{for any partitions } \mu \text{ and } \nu \text{ satisfying } |\mu| \neq |\nu| . \tag{13.121.5}$$

Now, let μ and ν be two partitions. We need to prove that $s_\mu * s_\nu \in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda$. This is obvious (because of (13.121.5)) in the case when $|\mu| \neq |\nu|$, so we can WLOG assume that $|\mu| = |\nu|$. Assume this, and let $n = |\mu| = |\nu|$. Consider the two irreducible characters χ^μ and χ^ν of $\mathbb{C}\mathfrak{S}_n$ defined as in Theorem 4.4.1(a). Then, $\chi^\mu = \chi_{U_1}$ and $\chi^\nu = \chi_{U_2}$ for two $\mathbb{C}\mathfrak{S}_n$-modules U_1 and U_2. Consider these U_1 and U_2. We have $\operatorname{ch}\left(\underbrace{\chi_{U_1}}_{=\chi^\mu}\right) = \operatorname{ch}(\chi^\mu) = s_\mu$ (by Theorem 4.4.1(a)) and similarly $\operatorname{ch}(\chi_{U_2}) = s_\nu$. But $U_1 \boxtimes U_2$ (being a $\mathbb{C}\mathfrak{S}_n$-module) must be a direct sum of finitely many irreducible $\mathbb{C}\mathfrak{S}_n$-modules, and thus the character $\chi_{U_1 \boxtimes U_2}$ is the sum of finitely many irreducible characters of $\mathbb{C}\mathfrak{S}_n$. Since the irreducible characters of $\mathbb{C}\mathfrak{S}_n$ are the χ^λ for $\lambda \in \operatorname{Par}_n$, this shows that $\chi_{U_1 \boxtimes U_2}$ is the sum of finitely many χ^λ. In other words, $\chi_{U_1 \boxtimes U_2} \in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} \chi^\lambda$. Applying the map ch to both sides of this relation, we obtain

$$\begin{aligned} \operatorname{ch}(\chi_{U_1 \boxtimes U_2}) \in \operatorname{ch}\left(\sum_{\lambda \in \operatorname{Par}} \mathbb{N} \chi^\lambda\right) &= \sum_{\lambda \in \operatorname{Par}} \mathbb{N} \underbrace{\operatorname{ch}\left(\chi^\lambda\right)}_{\substack{=s_\lambda \\ \text{(by Theorem 4.4.1(a))}}} \qquad \text{(since ch is } \mathbb{Z}\text{-linear)} \\ &= \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda . \end{aligned}$$

Hence, $\underline{1}_\lambda * \underline{1}_\mu = \delta_{\lambda,\mu} \underline{1}_\lambda$. Applying the map ch to this equality, we obtain

$$\operatorname{ch}\left(\underline{1}_\lambda * \underline{1}_\mu\right) = \operatorname{ch}\left(\delta_{\lambda,\mu} \underline{1}_\lambda\right) = \delta_{\lambda,\mu} \underbrace{\operatorname{ch}\left(\underline{1}_\lambda\right)}_{\substack{=\frac{p_\lambda}{z_\lambda} \\ \text{(by Theorem 4.4.1(a))}}} = \delta_{\lambda,\mu} \frac{p_\lambda}{z_\lambda} = \delta_{\lambda,\mu} z_\lambda^{-1} p_\lambda .$$

Compared with

$$\begin{aligned} &\underbrace{\left(\operatorname{ch}\left(\underline{1}_\lambda\right)\right)}_{\substack{=\frac{p_\lambda}{z_\lambda} \\ \text{(by Theorem 4.4.1(a))}}} * \underbrace{\left(\operatorname{ch}\left(\underline{1}_\mu\right)\right)}_{\substack{=\frac{p_\mu}{z_\mu} \\ \text{(by Theorem 4.4.1(a))}}} \\ &= \frac{p_\lambda}{z_\lambda} * \frac{p_\mu}{z_\mu} = z_\lambda^{-1} z_\mu^{-1} \underbrace{p_\lambda * p_\mu}_{\substack{=\delta_{\lambda,\mu} z_\lambda p_\lambda \\ \text{(by the definition of } *)}} = z_\lambda^{-1} z_\mu^{-1} \delta_{\lambda,\mu} z_\lambda p_\lambda = \underbrace{\delta_{\lambda,\mu} z_\mu^{-1}}_{\substack{=\delta_{\lambda,\mu} z_\lambda^{-1} \\ \text{(because the two sides of this} \\ \text{equality are equal if } \lambda=\mu \text{, and} \\ \text{vanish otherwise)}}} p_\lambda = \delta_{\lambda,\mu} z_\lambda^{-1} p_\lambda , \end{aligned}$$

this yields $\operatorname{ch}\left(\underline{1}_\lambda * \underline{1}_\mu\right) = \left(\operatorname{ch}\left(\underline{1}_\lambda\right)\right) * \left(\operatorname{ch}\left(\underline{1}_\mu\right)\right)$. This rewrites as $\operatorname{ch}(a * b) = (\operatorname{ch} a) * (\operatorname{ch} b)$ (since $a = \underline{1}_\lambda$ and $b = \underline{1}_\mu$). Thus, (13.121.4) is proven.

Since

$$\begin{aligned}\operatorname{ch}\left(\chi_{U_1 \boxtimes U_2}\right) &= \underbrace{\operatorname{ch}\left(\chi_{U_1}\right)}_{=s_\mu} * \underbrace{\operatorname{ch}\left(\chi_{U_2}\right)}_{=s_\nu} \qquad \text{(by Exercise 4.4.8(a))} \\ &= s_\mu * s_\nu,\end{aligned}$$

this rewrites as $s_\mu * s_\nu \in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda$. This solves Exercise 4.4.8(c).

(b) *Alternative solution of Exercise 2.9.4(h).* We need to prove that $f * g \in \Lambda$ for any $f \in \Lambda$ and $g \in \Lambda$. Since the binary operation $*$ is $\mathbb{Z}$-bilinear, it is clearly enough to prove that $s_\mu * s_\nu \in \Lambda$ for any partitions μ and ν (since $(s_\lambda)_{\lambda \in \operatorname{Par}}$ is a $\mathbb{Z}$-basis of Λ). But this follows from the fact that

$$\begin{aligned}s_\mu * s_\nu &\in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda \qquad \text{(by Exercise 4.4.8(c))} \\ &\subset \Lambda\end{aligned}$$

for any partitions μ and ν. Thus, Exercise 2.9.4 (h) is solved again.

13.122. **Solution to Exercise 4.4.9.** *Solution to Exercise 4.4.9.* Let us introduce a fundamental construction. If X is any set, then we let $\mathfrak{S}_X$ denote the symmetric group on X (that is, the group of all permutations of X). For any two sets X and Y and any permutations $\sigma \in \mathfrak{S}_X$ and $\tau \in \mathfrak{S}_Y$, we define a permutation $\sigma \times \tau$ of $X \times Y$ by setting

$$(\sigma \times \tau)((x, y)) = (\sigma(x), \tau(y)) \qquad \text{for every } x \in X \text{ and } y \in Y.$$

Thus, for any two sets X and Y, we can define a map

$$\begin{aligned}\operatorname{cross} : \mathfrak{S}_X \times \mathfrak{S}_Y &\to \mathfrak{S}_{X \times Y}, \\ (\sigma, \tau) &\mapsto \sigma \times \tau.\end{aligned}$$

We notice a few properties of this map (whose simple proof we leave to the reader):

Lemma 13.122.1. *Let X and Y be two sets.*

(a) *The map* cross $: \mathfrak{S}_X \times \mathfrak{S}_Y \to \mathfrak{S}_{X \times Y}$ *is a group homomorphism.*
(b) *If the sets X and Y are nonempty, then the map* cross $: \mathfrak{S}_X \times \mathfrak{S}_Y \to \mathfrak{S}_{X \times Y}$ *is injective.*

The following deeper fact provides the first hint of a combinatorial interpretation of $\boxdot$:

Lemma 13.122.2. *Let X and Y be two finite sets. Let $\sigma \in \mathfrak{S}_X$ and $\tau \in \mathfrak{S}_Y$ be two permutations. Let λ, μ and κ be the cycle types of the permutations $\sigma \in \mathfrak{S}_X$, $\tau \in \mathfrak{S}_Y$ and $\sigma \times \tau \in \mathfrak{S}_{X \times Y}$. Then,*

$$p_\lambda \boxdot p_\mu = p_\kappa.$$

Proof of Lemma 13.122.2. The partition λ is the cycle type of the permutation σ. In other words, $\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)}$ are the lengths of the cycles of the permutation σ. Let $C_1, C_2, \ldots, C_{\ell(\lambda)}$ denote these cycles, labelled in such a way that each C_i has length λ_i. Clearly, $\left(C_1, C_2, \ldots, C_{\ell(\lambda)}\right)$ is a set partition of the set X; thus, $X = \bigsqcup_{i=1}^{\ell(\lambda)} C_i$.

The partition μ is the cycle type of the permutation τ. In other words, $\mu_1, \mu_2, \ldots, \mu_{\ell(\mu)}$ are the lengths of the cycles of the permutation τ. Let $D_1, D_2, \ldots, D_{\ell(\mu)}$ denote these cycles, labelled in such a way that each D_j has length μ_j. Clearly, $\left(D_1, D_2, \ldots, D_{\ell(\mu)}\right)$ is a set partition of the set Y; thus, $Y = \bigsqcup_{j=1}^{\ell(\mu)} D_j$.

Since $X = \bigsqcup_{i=1}^{\ell(\lambda)} C_i$ and $Y = \bigsqcup_{j=1}^{\ell(\mu)} D_j$, we have

$$X \times Y = \left(\bigsqcup_{i=1}^{\ell(\lambda)} C_i\right) \times \left(\bigsqcup_{j=1}^{\ell(\mu)} D_j\right) = \bigsqcup_{i=1}^{\ell(\lambda)} \bigsqcup_{j=1}^{\ell(\mu)} (C_i \times D_j).$$

In particular, the sets $C_i \times D_j$ for (i, j) ranging over all $(i, j) \in \{1, 2, \ldots, \ell(\lambda)\} \times \{1, 2, \ldots, \ell(\mu)\}$ are disjoint.

We now make the following claim:

> *Claim A:* Let $i \in \{1, 2, \ldots, \ell(\lambda)\}$ and $j \in \{1, 2, \ldots, \ell(\mu)\}$. Then, the subset $C_i \times D_j$ of $X \times Y$ is the union of $\gcd(\lambda_i, \mu_j)$ disjoint cycles of the permutation $\sigma \times \tau$, and each of these cycles has length $\operatorname{lcm}(\lambda_i, \mu_j)$.

Proof of Claim A: We know that C_i is a cycle of σ; thus, $\sigma(C_i) \subset C_i$. Similarly, $\tau(D_j) \subset D_j$. Now, $(\sigma \times \tau)(C_i \times D_j) = \underbrace{\sigma(C_i)}_{\subset C_i} \times \underbrace{\tau(D_j)}_{\subset D_j} \subset C_i \times D_j$. Hence, the permutation $\sigma \times \tau$ restricts to a permutation of the subset $C_i \times D_j$ of $X \times Y$.

Let us first show that, for every $h \in C_i \times D_j$, the cycle of $\sigma \times \tau$ containing h is a subset of $C_i \times D_j$ and has length $\operatorname{lcm}(\lambda_i, \mu_j)$.

Indeed, fix $h \in C_i \times D_j$. Then, all of the elements $h, (\sigma \times \tau)(h), (\sigma \times \tau)^2(h), (\sigma \times \tau)^3(h), \ldots$ belong to $C_i \times D_j$ [887]. Hence, the cycle of $\sigma \times \tau$ containing h is a subset of $C_i \times D_j$ (because this cycle consists of these very elements $h, (\sigma \times \tau)(h), (\sigma \times \tau)^2(h), (\sigma \times \tau)^3(h), \ldots$). The length of this cycle is the smallest positive integer N such that $(\sigma \times \tau)^N(h) = h$. We shall now prove that this smallest positive integer is $\operatorname{lcm}(\lambda_i, \mu_j)$.

Indeed, let us write h in the form $h = (c, d)$ for some $c \in C_i$ and $d \in D_j$. Then, the element c belongs to a cycle of σ which has length λ_i (namely, C_i). Hence, the sequence $c, \sigma(c), \sigma^2(c), \sigma^3(c), \ldots$ repeats every λ_i elements (and not more frequently). Thus, for any $N \in \mathbb{N}$, we have the following equivalence of statements:

$$\left(\sigma^N(c) = c\right) \iff (\lambda_i \mid N).$$

Similarly, for any $N \in \mathbb{N}$, we have the following equivalence of statements:

$$\left(\tau^N(d) = d\right) \iff (\mu_j \mid N).$$

Now, for any $N \in \mathbb{N}$, we have the following equivalence of statements:

$$\begin{aligned}\left((\sigma \times \tau)^N(h) = h\right) &\iff \left(\underbrace{(\sigma \times \tau)^N((c,d))}_{=(\sigma^N(c), \tau^N(d))} = (c,d)\right) \qquad (\text{since } h = (c,d)) \\ &\iff \left(\left(\sigma^N(c), \tau^N(d)\right) = (c,d)\right) \iff \left(\underbrace{\left(\sigma^N(c) = c\right)}_{\iff (\lambda_i \mid N)} \text{ and } \underbrace{\left(\tau^N(d) = d\right)}_{\iff (\mu_j \mid N)}\right) \\ &\iff (\lambda_i \mid N \text{ and } \mu_j \mid N) \iff (\operatorname{lcm}(\lambda_i, \mu_j) \mid N).\end{aligned}$$

Thus, the smallest positive integer N such that $(\sigma \times \tau)^N(h) = h$ is $\operatorname{lcm}(\lambda_i, \mu_j)$. In other words, the length of the cycle of $\sigma \times \tau$ containing h is $\operatorname{lcm}(\lambda_i, \mu_j)$ (since the length of the cycle of $\sigma \times \tau$ containing h is the smallest positive integer N such that $(\sigma \times \tau)^N(h) = h$).

Now, let us forget that we fixed h. We thus have proven that, for every $h \in C_i \times D_j$,

$$\text{the cycle of } \sigma \times \tau \text{ containing } h \text{ is a subset of } C_i \times D_j \text{ and has length } \operatorname{lcm}(\lambda_i, \mu_j). \tag{13.122.1}$$

These cycles (for h ranging over all $C_i \times D_j$) clearly cover the set $C_i \times D_j$ (because each $h \in C_i \times D_j$ is contained in its corresponding cycle). Thus, $C_i \times D_j$ is the union of several cycles of the permutation $\sigma \times \tau$, and each of these cycles has length $\operatorname{lcm}(\lambda_i, \mu_j)$. Since any two cycles of $\sigma \times \tau$ are either disjoint or identical, we can get rid of redundant cycles in this union, and thus obtain the following conclusion: $C_i \times D_j$ is the union of several disjoint cycles of the permutation $\sigma \times \tau$, and each of these cycles has length $\operatorname{lcm}(\lambda_i, \mu_j)$. In order to complete the proof of Claim A, it thus remains only to show that the number of these cycles is $\gcd(\lambda_i, \mu_j)$. But this is easy: These cycles are all disjoint, and cover a set of size $\lambda_i \mu_j$ (in fact, they cover the set $C_i \times D_j$, which has size $|C_i \times D_j| = \underbrace{|C_i|}_{=\lambda_i} \cdot \underbrace{|D_j|}_{=\mu_j} = \lambda_i \mu_j$); since they have length $\operatorname{lcm}(\lambda_i, \mu_j)$ each, their number must be $\dfrac{\lambda_i \mu_j}{\operatorname{lcm}(\lambda_i, \mu_j)} = \gcd(\lambda_i, \mu_j)$. Thus, the proof of Claim A is complete.

We shall now continue our proof of Lemma 13.122.2.

[887] since the permutation $\sigma \times \tau$ restricts to a permutation of the subset $C_i \times D_j$ of $X \times Y$

The partition κ is the cycle type of the permutation $\sigma \times \tau$. In other words, $\kappa_1, \kappa_2, \ldots, \kappa_{\ell(\kappa)}$ are the lengths of the cycles of the permutation $\sigma \times \tau$. Hence,

$$\prod_{u=1}^{\ell(\kappa)} p_{\kappa_u} = \prod_{E \text{ is a cycle of } \sigma\times\tau} p_{|E|},$$

where $|E|$ denotes the length of any cycle E. But every cycle E of $\sigma \times \tau$ must satisfy $E \subset C_i \times D_j$ (where we regard E as a set) for precisely one $(i,j) \in \{1,2,\ldots,\ell(\lambda)\} \times \{1,2,\ldots,\ell(\mu)\}$ [888]. Hence,

$$\prod_{E \text{ is a cycle of } \sigma\times\tau} p_{|E|} = \prod_{i=1}^{\ell(\lambda)} \prod_{j=1}^{\ell(\mu)} \prod_{\substack{E \text{ is a cycle of } \sigma\times\tau;\\ E\subset C_i\times D_j}} p_{|E|}.$$

But every $(i,j) \in \{1,2,\ldots,\ell(\lambda)\} \times \{1,2,\ldots,\ell(\mu)\}$ satisfies

$$\prod_{\substack{E \text{ is a cycle of } \sigma\times\tau;\\ E\subset C_i\times D_j}} p_{|E|} = p_{\operatorname{lcm}(\lambda_i,\mu_j)}^{\gcd(\lambda_i,\mu_j)}$$

[889]. Now, the definition of p_κ yields

$$p_\kappa = p_{\kappa_1} p_{\kappa_2} \cdots p_{\kappa_{\ell(\kappa)}} = \prod_{u=1}^{\ell(\kappa)} p_{\kappa_u} = \prod_{E \text{ is a cycle of } \sigma\times\tau} p_{|E|} = \prod_{i=1}^{\ell(\lambda)} \prod_{j=1}^{\ell(\mu)} \underbrace{\prod_{\substack{E \text{ is a cycle of } \sigma\times\tau;\\ E\subset C_i\times D_j}} p_{|E|}}_{=p_{\operatorname{lcm}(\lambda_i,\mu_j)}^{\gcd(\lambda_i,\mu_j)}}$$

$$= \prod_{i=1}^{\ell(\lambda)} \prod_{j=1}^{\ell(\mu)} p_{\operatorname{lcm}(\lambda_i,\mu_j)}^{\gcd(\lambda_i,\mu_j)} = p_\lambda \boxdot p_\mu \qquad \left(\text{since } p_\lambda \boxdot p_\mu \text{ is defined to be } \prod_{i=1}^{\ell(\lambda)} \prod_{j=1}^{\ell(\mu)} p_{\operatorname{lcm}(\lambda_i,\mu_j)}^{\gcd(\lambda_i,\mu_j)}\right).$$

This proves Lemma 13.122.2. □

(a) We already know that the operation $\boxdot$ is $\mathbb{Q}$-bilinear. Thus, we only need to prove that the binary operation $\boxdot$ is commutative and associative and has unity p_1.

We shall only prove the associativity of $\boxdot$ (since the other two properties can be proven similarly). In other words, we shall prove that $(u \boxdot v) \boxdot w = u \boxdot (v \boxdot w)$ for any three elements u, v and w of $\Lambda_{\mathbb{Q}}$.

So let u, v and w be three elements of $\Lambda_{\mathbb{Q}}$. We need to prove the equality $(u \boxdot v) \boxdot w = u \boxdot (v \boxdot w)$. Since this equality is $\mathbb{Q}$-linear in each of u, v and w (this is because the operation $\boxdot$ is $\mathbb{Q}$-bilinear), we can WLOG assume that u, v and w belong to the basis $(p_\lambda)_{\lambda\in\mathrm{Par}}$ of the $\mathbb{Q}$-vector space $\Lambda_{\mathbb{Q}}$. Assume this. Then, there exist three partitions λ, μ and ν such that $u = p_\lambda$, $v = p_\mu$ and $w = p_\nu$. Consider these λ, μ and ν.

There exist a finite set A and a permutation $\alpha \in \mathfrak{S}_A$ such that λ is the cycle type of α. Consider these A and α.

[888] *Proof.* Let E be a cycle of $\sigma \times \tau$. Then, E is nonempty, so that there exists an element h of E. Fix such an h. We have $h \in E \subset X \times Y = \bigsqcup_{i=1}^{\ell(\lambda)} \bigsqcup_{j=1}^{\ell(\mu)} (C_i \times D_j)$. Hence, there exists some $(i,j) \in \{1,2,\ldots,\ell(\lambda)\} \times \{1,2,\ldots,\ell(\mu)\}$ such that $h \in C_i \times D_j$. Consider this (i,j). Then, E is the cycle of $\sigma \times \tau$ containing h. Hence, (13.122.1) shows that E is a subset of $C_i \times D_j$ and has length $\operatorname{lcm}(\lambda_i, \mu_j)$. So we know that $E \subset C_i \times D_j$.

So we have found a pair $(i,j) \in \{1,2,\ldots,\ell(\lambda)\} \times \{1,2,\ldots,\ell(\mu)\}$ such that $E \subset C_i \times D_j$. There clearly cannot be two distinct such pairs (i,j) (since the sets $C_i \times D_j$ for (i,j) ranging over all $(i,j) \in \{1,2,\ldots,\ell(\lambda)\} \times \{1,2,\ldots,\ell(\mu)\}$ are disjoint), and so this pair (i,j) is unique.

[889] *Proof.* Let $(i,j) \in \{1,2,\ldots,\ell(\lambda)\} \times \{1,2,\ldots,\ell(\mu)\}$. Claim A yields that the subset $C_i \times D_j$ of $X \times Y$ is the union of $\gcd(\lambda_i, \mu_j)$ disjoint cycles of the permutation $\sigma \times \tau$, and each of these cycles has length $\operatorname{lcm}(\lambda_i, \mu_j)$. Obviously, these $\gcd(\lambda_i, \mu_j)$ disjoint cycles are exactly all the cycles E of $\sigma \times \tau$ which satisfy $E \subset C_i \times D_j$. Thus, there are precisely $\gcd(\lambda_i, \mu_j)$ cycles E of $\sigma \times \tau$ which satisfy $E \subset C_i \times D_j$, and each of these cycles E has length $\operatorname{lcm}(\lambda_i, \mu_j)$. Hence,

$$\prod_{\substack{E \text{ is a cycle of } \sigma\times\tau;\\ E\subset C_i\times D_j}} \underbrace{p_{|E|}}_{\substack{=p_{\operatorname{lcm}(\lambda_i,\mu_j)}\\ \text{(since } E \text{ has length } \operatorname{lcm}(\lambda_i,\mu_j),\\ \text{that is, we have } |E|=\operatorname{lcm}(\lambda_i,\mu_j))}} = \prod_{\substack{E \text{ is a cycle of } \sigma\times\tau;\\ E\subset C_i\times D_j}} p_{\operatorname{lcm}(\lambda_i,\mu_j)} = p_{\operatorname{lcm}(\lambda_i,\mu_j)}^{\gcd(\lambda_i,\mu_j)}$$

(since there are precisely $\gcd(\lambda_i, \mu_j)$ cycles E of $\sigma \times \tau$ which satisfy $E \subset C_i \times D_j$), qed.

There exist a finite set B and a permutation $\beta \in \mathfrak{S}_B$ such that μ is the cycle type of β. Consider these B and β.

There exist a finite set C and a permutation $\gamma \in \mathfrak{S}_C$ such that ν is the cycle type of γ. Consider these C and γ.

For every permutation π of any finite set X, we let $\operatorname{type}\pi$ denote the cycle type of π. Lemma 13.122.2 (applied to $X = A$, $Y = B$, $\sigma = \alpha$, $\tau = \beta$ and $\kappa = \operatorname{type}(\alpha \times \beta)$) yields $p_\lambda \boxdot p_\mu = p_{\operatorname{type}(\alpha\times\beta)}$. Lemma 13.122.2 (applied to $A \times B$, C, $\alpha \times \beta$, γ, $\operatorname{type}(\alpha \times \beta)$, ν and $\operatorname{type}((\alpha \times \beta) \times \gamma)$ instead of X, Y, σ, τ, λ, μ and κ) yields $p_{\operatorname{type}(\alpha\times\beta)} \boxdot p_\nu = p_{\operatorname{type}((\alpha\times\beta)\times\gamma)}$. Thus,

$$\left(\underbrace{u}_{=p_\lambda} \boxdot \underbrace{v}_{=p_\mu}\right) \boxdot \underbrace{w}_{=p_\nu} = \underbrace{(p_\lambda \boxdot p_\mu)}_{=p_{\operatorname{type}(\alpha\times\beta)}} \boxdot p_\nu = p_{\operatorname{type}(\alpha\times\beta)} \boxdot p_\nu = p_{\operatorname{type}((\alpha\times\beta)\times\gamma)}.$$

A similar argument shows that $u \boxdot (v \boxdot w) = p_{\operatorname{type}(\alpha\times(\beta\times\gamma))}$.

Let us now say that if U and V are two finite sets, and if $\sigma \in \mathfrak{S}_U$ and $\tau \in \mathfrak{S}_V$ are two permutations, then the permutations σ and τ are *isomorphic* if and only if there exists a bijection $\varphi : U \to V$ such that $\varphi \circ \sigma = \tau \circ \varphi$. The intuition behind this meaning of "isomorphism" is that two permutations are isomorphic if one of them becomes the other after a relabelling of its ground set. It is clear that two isomorphic permutations of finite sets must have the same cycle type.

But the permutations $(\alpha \times \beta) \times \gamma \in \mathfrak{S}_{(A\times B)\times C}$ and $\alpha \times (\beta \times \gamma) \in \mathfrak{S}_{A\times(B\times C)}$ are isomorphic (as witnessed by the bijection $\varphi : (A \times B) \times C \to A \times (B \times C)$ sending every $((a, b), c) \in (A \times B) \times C$ to $(a, (b, c))$). Hence, $\operatorname{type}((\alpha \times \beta) \times \gamma) = \operatorname{type}(\alpha \times (\beta \times \gamma))$ (since two isomorphic permutations of finite sets must have the same cycle type). Thus,

$$\begin{aligned}(u \boxdot v) \boxdot w &= p_{\operatorname{type}((\alpha\times\beta)\times\gamma)} = p_{\operatorname{type}(\alpha\times(\beta\times\gamma))} && (\text{since } \operatorname{type}((\alpha \times \beta) \times \gamma) = \operatorname{type}(\alpha \times (\beta \times \gamma)))\\ &= u \boxdot (v \boxdot w).\end{aligned}$$

This finishes the proof of the equality $(u \boxdot v) \boxdot w = u \boxdot (v \boxdot w)$, and thus Exercise 4.4.9(a) is solved.

(b) Let $f \in \Lambda_{\mathbb{Q}}$. We need to prove the equality $1 \boxdot f = \epsilon_1(f) 1$. Since this equality is $\mathbb{Q}$-linear in f (because the operation $\boxdot$ is $\mathbb{Q}$-bilinear and the map ϵ_1 is $\mathbb{Q}$-linear), we can WLOG assume that f belongs to the basis $(p_\lambda)_{\lambda\in\operatorname{Par}}$ of the $\mathbb{Q}$-vector space $\Lambda_{\mathbb{Q}}$. Assume this. Then, there exists a partition λ such that $f = p_\lambda$. Consider this λ. The definition of $p_\varnothing \boxdot p_\lambda$ yields

$$\begin{aligned}p_\varnothing \boxdot p_\lambda &= \prod_{i=1}^{\ell(\varnothing)} \prod_{j=1}^{\ell(\lambda)} p_{\operatorname{lcm}(\varnothing_i,\lambda_j)}^{\gcd(\varnothing_i,\lambda_j)} = \prod_{i=1}^{0} \prod_{j=1}^{\ell(\lambda)} p_{\operatorname{lcm}(\varnothing_i,\lambda_j)}^{\gcd(\varnothing_i,\lambda_j)} && (\text{since } \ell(\varnothing) = 0)\\ &= (\text{empty product}) = 1.\end{aligned}$$

Hence, $\underbrace{1}_{=p_\varnothing} \boxdot \underbrace{f}_{=p_\lambda} = p_\varnothing \boxdot p_\lambda = 1$.

On the other hand, $\epsilon_1(p_\lambda) = 1$ [890]. Thus, $\epsilon_1\left(\underbrace{f}_{=p_\lambda}\right) = \epsilon_1(p_\lambda) = 1$. Hence, $1 \boxdot f = 1 = \epsilon_1(f) = \epsilon_1(f) 1$. This solves Exercise 4.4.9(b).

(c) For every finite group G and every $h \in G$, we define a class function $\alpha_{G,h} \in R_{\mathbb{C}}(G)$ as in Exercise 4.4.3.

[890] *Proof.* We have $\lambda = (\lambda_1, \lambda_2, \ldots, \lambda_{\ell(\lambda)})$. Thus, the definition of p_λ yields $p_\lambda = p_{\lambda_1} p_{\lambda_2} \cdots p_{\lambda_{\ell(\lambda)}} = \prod_{i=1}^{\ell(\lambda)} p_{\lambda_i}$. Applying the map ϵ_1 to both sides of this equality, we conclude

$$\begin{aligned}\epsilon_1(p_\lambda) &= \epsilon_1\left(\prod_{i=1}^{\ell(\lambda)} p_{\lambda_i}\right) = \prod_{i=1}^{\ell(\lambda)} \underbrace{\epsilon_1(p_{\lambda_i})}_{\substack{=1\\ (\text{by the definition}\\ \text{of } \epsilon_1)}} && (\text{since } \epsilon_1 \text{ is a } \mathbb{Q}\text{-algebra homomorphism})\\ &= \prod_{i=1}^{\ell(\lambda)} 1 = 1,\end{aligned}$$

qed.

We next recall the notation U^τ defined in Definition 4.3.3. We state a few properties of this notation:

Lemma 13.122.3. *Let K and H be two finite groups. Let $\tau : K \to H$ be a group homomorphism.*

(a) *For every $f \in R_{\mathbb{C}}(H)$, the map $f \circ \tau : K \to \mathbb{C}$ belongs to $R_{\mathbb{C}}(K)$. We can thus define a $\mathbb{C}$-linear map $\tau^* : R_{\mathbb{C}}(H) \to R_{\mathbb{C}}(K)$ by*

$$(\tau^*(f) = f \circ \tau \qquad \text{for every } f \in R_{\mathbb{C}}(H)).$$

(b) *For every (finite-dimensional) $\mathbb{C}H$-module U, we have $\chi_{U^\tau} = \tau^*(\chi_U)$.*

(c) *We have $\tau^*(R(H)) \subset R(K)$.*

(d) *Assume that $\tau : K \to H$ is a group isomorphism. Then, $\tau^*\left(\alpha_{H,\tau(g)}\right) = \alpha_{K,g}$ for every $g \in K$.*

The proof of Lemma 13.122.3 is straightforward and left to the reader. (We will not use its part (c).)

Finally, here come two more simple facts whose proofs we leave to the reader:

Lemma 13.122.4. *Let G and H be two groups. Let $\Omega : G \to H$ be an injective group homomorphism. Define a map $\overline{\Omega} : G \to \Omega(G)$ by*

$$\left(\overline{\Omega}(g) = \Omega(g) \qquad \text{for every } g \in G\right).$$

Then, $\overline{\Omega}$ is a well-defined group isomorphism.

Lemma 13.122.5. *Let U and V be two finite sets. Let $\varphi : U \to V$ be a bijection. Define a map $\varphi^* : \mathfrak{S}_U \to \mathfrak{S}_V$ by*

$$\left(\varphi^*(\pi) = \varphi \circ \pi \circ \varphi^{-1} \qquad \text{for every } \pi \in \mathfrak{S}_U\right).$$

(a) *This map φ^* is well-defined and a group isomorphism.*

(b) *Let $\pi \in \mathfrak{S}_U$. Then, the cycle type of $\varphi^*(\pi)$ equals the cycle type of π.*

Recall that $\boxdot$ is a $\mathbb{Q}$-bilinear map $\Lambda_{\mathbb{Q}} \times \Lambda_{\mathbb{Q}} \to \Lambda_{\mathbb{Q}}$. Let us extend $\boxdot$ to a $\mathbb{C}$-bilinear map $\Lambda_{\mathbb{C}} \times \Lambda_{\mathbb{C}} \to \Lambda_{\mathbb{C}}$; we will still denote this extended map by $\boxdot$.

Recall that $\operatorname{ch} : A \to \Lambda$ is a $\mathbb{Z}$-Hopf algebra isomorphism. Hence, the extension of ch to a $\mathbb{C}$-linear map $A_{\mathbb{C}} \to \Lambda_{\mathbb{C}}$ is a $\mathbb{C}$-Hopf algebra isomorphism. We shall denote this extension by $\operatorname{ch}_{\mathbb{C}}$.

We are going to repeatedly use the following fact (which is easy to obtain from the solution of Exercise 4.4.3): If λ is a partition of a nonnegative integer n, and if $g \in \mathfrak{S}_n$ is a permutation having cycle type λ, then

$$\operatorname{ch}_{\mathbb{C}}\left(\alpha_{\mathfrak{S}_n,g}\right) = p_\lambda. \tag{13.122.2}$$

[891]

Theorem 4.4.1(a) yields $\operatorname{ch}\left(\chi^\lambda\right) = s_\lambda$ for every partition λ (where χ^λ is defined as in Theorem 4.4.1(a)). Since $\operatorname{ch}_{\mathbb{C}}$ is the extension of ch to a $\mathbb{C}$-linear map $A_{\mathbb{C}} \to \Lambda_{\mathbb{C}}$, we have

$$\operatorname{ch}_{\mathbb{C}}\left(\chi^\lambda\right) = \operatorname{ch}\left(\chi^\lambda\right) = s_\lambda \qquad \text{for every partition } \lambda. \tag{13.122.3}$$

Let us now come back to solving Exercise 4.4.9(c). Let μ and ν be two partitions. We need to show that $s_\mu \boxdot s_\nu \in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda$.

Let $m = |\mu|$ and $n = |\nu|$. Then, $\mu \in \operatorname{Par}_m$ and $\nu \in \operatorname{Par}_n$. If $\min\{m,n\} = 0$, then $s_\mu \boxdot s_\nu \in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda$ is easily seen to hold[892]. Hence, for the rest of this proof, we can WLOG assume that we don't have $\min\{m,n\} = 0$. Assume this. Thus, $\min\{m,n\} \geq 1$. Hence, $m \geq 1$ and $n \geq 1$.

[891] *Proof of (13.122.2):* Let λ be a partition of a nonnegative integer n. Let $g \in \mathfrak{S}_n$ be a permutation having cycle type λ. Define a map $\Phi : \Lambda_{\mathbb{C}} \to A_{\mathbb{C}}$ as in the solution of Exercise 4.4.3(d). Then, (13.117.8) yields $\Phi(p_\lambda) = \alpha_{\mathfrak{S}_n,g}$, so that $\alpha_{\mathfrak{S}_n,g} = \Phi(p_\lambda)$. But $\operatorname{ch}_{\mathbb{C}} \circ \Phi = \operatorname{id}_{\Lambda_{\mathbb{C}}}$ (this was shown in the solution of Exercise 4.4.3(d)). Now, $\operatorname{ch}_{\mathbb{C}}\left(\underbrace{\alpha_{\mathfrak{S}_n,g}}_{=\Phi(p_\lambda)}\right) = \operatorname{ch}_{\mathbb{C}}(\Phi(p_\lambda)) = \underbrace{(\operatorname{ch}_{\mathbb{C}} \circ \Phi)}_{=\operatorname{id}_{\Lambda_{\mathbb{C}}}}(p_\lambda) = \operatorname{id}_{\Lambda_{\mathbb{C}}}(p_\lambda) = p_\lambda$. This proves (13.122.2).

[892] *Proof.* Assume that $\min\{m,n\} = 0$.

Recall that $\Lambda_{\mathbb{Q}}$, equipped with the binary operation $\boxdot$, becomes a commutative $\mathbb{Q}$-algebra with unity p_1 (according to Exercise 4.4.9(a)). Thus, the operation $\boxdot$ is commutative. Hence, $s_\mu \boxdot s_\nu = s_\nu \boxdot s_\mu$.

We notice that

$$\text{(13.122.4)} \qquad \operatorname{ch}_{\mathbb{C}}(\chi_P) \in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda \qquad \text{for every finite-dimensional } \mathbb{C}\mathfrak{S}_{nm}\text{-module } P.$$

[893]

We have $\mathfrak{S}_n = \mathfrak{S}_{\{1,2,\ldots,n\}}$ (by the definition of $\mathfrak{S}_n$) and $\mathfrak{S}_m = \mathfrak{S}_{\{1,2,\ldots,m\}}$ (by the definition of $\mathfrak{S}_m$) and $\mathfrak{S}_{nm} = \mathfrak{S}_{\{1,2,\ldots,nm\}}$ (by the definition of $\mathfrak{S}_{nm}$). Recall that we have defined a map $\operatorname{cross} : \mathfrak{S}_X \times \mathfrak{S}_Y \to \mathfrak{S}_{X\times Y}$ for any two sets X and Y. Now, set $X = \{1,2,\ldots,n\}$ and $Y = \{1,2,\ldots,m\}$, and consider the map $\operatorname{cross} : \mathfrak{S}_X \times \mathfrak{S}_Y \to \mathfrak{S}_{X\times Y}$. In the following, when we speak of cross, we will always mean this map.

We have $\left|\underbrace{X}_{=\{1,2,\ldots,n\}}\right| = |\{1,2,\ldots,n\}| = n$ and $\left|\underbrace{Y}_{=\{1,2,\ldots,m\}}\right| = |\{1,2,\ldots,m\}| = m$. Also, since $X = \{1,2,\ldots,n\}$, we have $\mathfrak{S}_X = \mathfrak{S}_{\{1,2,\ldots,n\}} = \mathfrak{S}_n$. Similarly, $\mathfrak{S}_Y = \mathfrak{S}_m$.

The set X is nonempty (since $|X| = n \geq 1$), and the set Y is nonempty (similarly). Hence, Lemma 13.122.1(b) yields that the map $\operatorname{cross} : \mathfrak{S}_X \times \mathfrak{S}_Y \to \mathfrak{S}_{X\times Y}$ is injective. Lemma 13.122.1(a) yields that the map $\operatorname{cross} : \mathfrak{S}_X \times \mathfrak{S}_Y \to \mathfrak{S}_{X\times Y}$ is a group homomorphism. Thus, the map cross is a group homomorphism from $\mathfrak{S}_X \times \mathfrak{S}_Y$ to $\mathfrak{S}_{X\times Y}$. Since $\mathfrak{S}_X = \mathfrak{S}_n$ and $\mathfrak{S}_Y = \mathfrak{S}_m$, this rewrites as follows: The map cross is a group homomorphism from $\mathfrak{S}_n \times \mathfrak{S}_m$ to $\mathfrak{S}_{X\times Y}$.

The set $X \times Y$ has cardinality $|X \times Y| = \underbrace{|X|}_{=n} \cdot \underbrace{|Y|}_{=m} = nm$, and thus is in bijection with the set $\{1,2,\ldots,nm\}$. In other words, there exists a bijection $\varphi : X \times Y \to \{1,2,\ldots,nm\}$. Fix such a bijection φ. Define a map $\varphi^* : \mathfrak{S}_{X\times Y} \to \mathfrak{S}_{\{1,2,\ldots,nm\}}$ as in Lemma 13.122.5 (applied to $U = X \times Y$ and $V = \{1,2,\ldots,nm\}$). Then, Lemma 13.122.5(a) (applied to $U = X \times Y$ and $V = \{1,2,\ldots,nm\}$) yields that this map φ^* is well-defined and a group isomorphism. In particular, φ^* is an injective group homomorphism.

We can WLOG assume that $m \leq n$ (since otherwise, we can just interchange μ and m with ν and n (because $s_\mu \boxdot s_\nu = s_\nu \boxdot s_\mu$)). Assume this. Then, $\min\{m,n\} = m$, so that $m = \min\{m,n\} = 0$. Hence, $\mu \in \operatorname{Par}_m = \operatorname{Par}_0$ (since $m = 0$), so that $\mu = \varnothing$ and thus $s_\mu = s_\varnothing = 1$.

Let us use the notations of Exercise 4.4.9(b). We have $\underbrace{s_\mu}_{=1} \boxdot s_\nu = 1 \boxdot s_\nu = \epsilon_1(s_\nu)\,1$ (by Exercise 4.4.9(b), applied to $f = s_\nu$). But $\epsilon_1(s_\nu) = s_\nu(1)$ (by Exercise 2.9.4(i), applied to $f = s_\nu$) and $s_\nu(1) \in \mathbb{N}$ (since s_ν is a sum of monomials). Hence, $s_\mu \boxdot s_\nu = \underbrace{\epsilon_1(s_\nu)}_{\in\mathbb{N}}\underbrace{1}_{=s_\varnothing} \in \mathbb{N}s_\varnothing \subset \sum_{\lambda\in\operatorname{Par}} \mathbb{N}s_\lambda$, qed.

[893] *Proof of (13.122.4):* Let P be a finite-dimensional $\mathbb{C}\mathfrak{S}_{nm}$-module. Then, P must be a direct sum of finitely many simple $\mathbb{C}\mathfrak{S}_{nm}$-modules. In other words, there exist some simple $\mathbb{C}\mathfrak{S}_{nm}$-modules $V_1, V_2, \ldots, V_j$ such that $P \cong V_1 \oplus V_2 \oplus \cdots \oplus V_j$ as $\mathbb{C}\mathfrak{S}_{nm}$-modules. Consider these $V_1, V_2, \ldots, V_j$. We shall now show that $\chi_{V_i} \in \sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda$ for every $i \in \{1,2,\ldots,j\}$.

Indeed, let $i \in \{1,2,\ldots,j\}$. Then, V_i is a simple $\mathbb{C}\mathfrak{S}_{nm}$-module. Hence, χ_{V_i} is an irreducible character of $\mathbb{C}\mathfrak{S}_{nm}$. But (a part of) Theorem 4.4.1(a) (applied to nm instead of n) says that all irreducible characters of $\mathfrak{S}_{nm}$ have the form χ^λ with $\lambda \in \operatorname{Par}_{nm}$. Thus, χ_{V_i} has the form $\chi_{V_i} = \chi^\lambda$ for some $\lambda \in \operatorname{Par}_{nm}$. In other words, $\chi_{V_i} \in \left\{\chi^\lambda \mid \lambda \in \underbrace{\operatorname{Par}_{nm}}_{\subset\operatorname{Par}}\right\} \subset \left\{\chi^\lambda \mid \lambda \in \operatorname{Par}\right\} \subset \sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda$.

Now, let us forget that we fixed i. We thus have shown that $\chi_{V_i} \in \sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda$ for every $i \in \{1,2,\ldots,j\}$. Thus, $\sum_{i=1}^j \underbrace{\chi_{V_i}}_{\in\sum_{\lambda\in\operatorname{Par}}\mathbb{N}\chi^\lambda} \in \sum_{i=1}^j \sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda \subset \sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda$ (since $\sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda$ is closed under addition).

But isomorphic $\mathbb{C}\mathfrak{S}_{nm}$-modules have equal characters. Hence, since $P \cong V_1 \oplus V_2 \oplus \cdots \oplus V_j$, we have

$$\chi_P = \chi_{V_1\oplus V_2\oplus\cdots\oplus V_j} = \chi_{V_1} + \chi_{V_2} + \cdots + \chi_{V_j} = \sum_{i=1}^j \chi_{V_i} \in \sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda.$$

Applying the map $\operatorname{ch}_{\mathbb{C}}$ to both sides of this relation, we obtain

$$\begin{aligned} \operatorname{ch}_{\mathbb{C}}(\chi_P) &\in \operatorname{ch}_{\mathbb{C}}\left(\sum_{\lambda\in\operatorname{Par}} \mathbb{N}\chi^\lambda\right) \subset \sum_{\lambda\in\operatorname{Par}} \mathbb{N} \underbrace{\operatorname{ch}_{\mathbb{C}}\left(\chi^\lambda\right)}_{\substack{=s_\lambda \\ \text{(by (13.122.3))}}} \qquad \text{(since the map } \operatorname{ch}_{\mathbb{C}} \text{ is } \mathbb{Z}\text{-linear)} \\ &= \sum_{\lambda\in\operatorname{Par}} \mathbb{N}s_\lambda. \end{aligned}$$

This proves (13.122.4).

Also, φ^* is a group homomorphism from $\mathfrak{S}_{X\times Y}$ to $\mathfrak{S}_{\{1,2,\ldots,nm\}}$, therefore a group homomorphism from $\mathfrak{S}_{X\times Y}$ to $\mathfrak{S}_{nm}$ (since $\mathfrak{S}_{nm} = \mathfrak{S}_{\{1,2,\ldots,nm\}}$).

Hence, $\varphi^* \circ \operatorname{cross}$ is a group homomorphism from $\mathfrak{S}_n \times \mathfrak{S}_m$ to $\mathfrak{S}_{nm}$ (since φ^* is a group homomorphism from $\mathfrak{S}_{X\times Y}$ to $\mathfrak{S}_{nm}$, and since cross is a group homomorphism from $\mathfrak{S}_n \times \mathfrak{S}_m$ to $\mathfrak{S}_{X\times Y}$). Also, $\varphi^* \circ \operatorname{cross}$ is injective (since φ^* and cross are injective). Let $\Omega = \varphi^* \circ \operatorname{cross}$. Then, Ω is an injective group homomorphism from $\mathfrak{S}_n \times \mathfrak{S}_m$ to $\mathfrak{S}_{nm}$ (since $\varphi^* \circ \operatorname{cross}$ is an injective group homomorphism from $\mathfrak{S}_n \times \mathfrak{S}_m$ to $\mathfrak{S}_{nm}$). We can define a map $\overline{\Omega} : \mathfrak{S}_n \times \mathfrak{S}_m \to \Omega\left(\mathfrak{S}_n \times \mathfrak{S}_m\right)$ by

$$\left(\overline{\Omega}\left(g\right) = \Omega\left(g\right) \qquad \text{for every } g \in \mathfrak{S}_n \times \mathfrak{S}_m\right)$$

(since $\Omega\left(g\right) \in \Omega\left(\mathfrak{S}_n \times \mathfrak{S}_m\right)$ for every $g \in \mathfrak{S}_n \times \mathfrak{S}_m$). Consider this $\overline{\Omega}$. Lemma 13.122.4 (applied to $\mathfrak{S}_n \times \mathfrak{S}_m$ and $\mathfrak{S}_{nm}$ instead of G and H) yields that $\overline{\Omega}$ is a well-defined group isomorphism. Hence, the inverse $\overline{\Omega}^{-1}$ of $\overline{\Omega}$ is well-defined and also a group isomorphism. Let τ denote this inverse $\overline{\Omega}^{-1}$. Thus,

$$\tau = \overline{\Omega}^{-1} \text{ is a group isomorphism } \Omega\left(\mathfrak{S}_n \times \mathfrak{S}_m\right) \to \mathfrak{S}_n \times \mathfrak{S}_m.$$

Hence, a $\mathbb{C}$-linear map $\tau^* : R_{\mathbb{C}}\left(\mathfrak{S}_n \times \mathfrak{S}_m\right) \to R_{\mathbb{C}}\left(\Omega\left(\mathfrak{S}_n \times \mathfrak{S}_m\right)\right)$ is defined (according to Lemma 13.122.3(a), applied to $\Omega\left(\mathfrak{S}_n \times \mathfrak{S}_m\right)$ and $\mathfrak{S}_n \times \mathfrak{S}_m$ instead of K and H).

The following commutative diagram illustrates the group homomorphisms we have just introduced:

$$\begin{tikzcd}
\mathfrak{S}_n \times \mathfrak{S}_m \arrow[r, hook, "\text{cross}"] \arrow[rr, bend left=40, "\Omega"] \arrow[dr, "\overline{\Omega}", "\cong"'] & \mathfrak{S}_{X\times Y} \arrow[r, "\varphi^*", "\cong"'] & \mathfrak{S}_{nm} \\
& \Omega\left(\mathfrak{S}_n \times \mathfrak{S}_m\right) \arrow[ur, hook, "\text{inclusion}"'] \arrow[ul, bend left=60, "\tau", "\cong"'] &
\end{tikzcd}$$

(where the cycle formed by the $\overline{\Omega}$ and τ arrows is not a mistake: these two maps are mutually inverse!).

In the following, for every $k \in \mathbb{N}$, we let $\left(\Lambda_{\mathbb{C}}\right)_k$ denote the k-th homogeneous component of the graded $\mathbb{C}$-algebra $\Lambda_{\mathbb{C}}$. Note that $\left(p_\lambda\right)_{\lambda \in \operatorname{Par}_k}$ is a basis of this $\mathbb{C}$-vector space $\left(\Lambda_{\mathbb{C}}\right)_k$.

Let us now claim that every $a \in \left(\Lambda_{\mathbb{C}}\right)_n$ and $b \in \left(\Lambda_{\mathbb{C}}\right)_m$ satisfy

$$a \boxdot b = \operatorname{ch}_{\mathbb{C}}\left(\operatorname{Ind}_{\Omega\left(\mathfrak{S}_n\times\mathfrak{S}_m\right)}^{\mathfrak{S}_{nm}}\left(\tau^*\left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(a\right) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(b\right)\right)\right)\right) \tag{13.122.5}$$

(where we identify $R_{\mathbb{C}}\left(\mathfrak{S}_n\right) \otimes R_{\mathbb{C}}\left(\mathfrak{S}_m\right)$ with $R_{\mathbb{C}}\left(\mathfrak{S}_n \times \mathfrak{S}_m\right)$ along the canonical isomorphism $R_{\mathbb{C}}\left(\mathfrak{S}_n\right) \otimes R_{\mathbb{C}}\left(\mathfrak{S}_m\right) \to R_{\mathbb{C}}\left(\mathfrak{S}_n \times \mathfrak{S}_m\right)$) [894].

Proof of (13.122.5): Let $a \in \left(\Lambda_{\mathbb{C}}\right)_n$ and $b \in \left(\Lambda_{\mathbb{C}}\right)_m$. We need to prove the equality (13.122.5). Since this equality is $\mathbb{C}$-linear in each of a and b (because the operations $\boxdot$ and $\otimes$ are $\mathbb{C}$-bilinear, and the maps $\operatorname{ch}_{\mathbb{C}}$ $\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}$, $\operatorname{Ind}_{\Omega\left(\mathfrak{S}_n\times\mathfrak{S}_m\right)}^{\mathfrak{S}_{nm}}$ and τ^* are $\mathbb{C}$-linear), we can WLOG assume that a is an element of the basis $\left(p_\lambda\right)_{\lambda \in \operatorname{Par}_n}$ of the $\mathbb{C}$-vector space $\left(\Lambda_{\mathbb{C}}\right)_n$, and that b is an element of the basis $\left(p_\lambda\right)_{\lambda \in \operatorname{Par}_m}$ of the $\mathbb{C}$-vector space $\left(\Lambda_{\mathbb{C}}\right)_m$. Assume this. Then, we can write a and b as $a = p_\gamma$ and $b = p_\eta$ for some $\gamma \in \operatorname{Par}_n$ and some $\eta \in \operatorname{Par}_m$. Consider these γ and η.

Choose some permutation $g \in \mathfrak{S}_n$ which has cycle type γ. (Such a g clearly exists.) Then, $\operatorname{ch}_{\mathbb{C}}\left(\alpha_{\mathfrak{S}_n,g}\right) = p_\gamma$ (according to (13.122.2)). Hence, $\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(p_\gamma\right) = \alpha_{\mathfrak{S}_n,g}$, so that $\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(\underbrace{a}_{=p_\gamma}\right) = \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(p_\gamma\right) = \alpha_{\mathfrak{S}_n,g}$.

[894] Notice that the term $\tau^*\left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(a\right) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(b\right)\right)$ on the right hand side of (13.122.5) is well-defined. (This is because

$$\begin{aligned}\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(\underbrace{a}_{\in\left(\Lambda_{\mathbb{C}}\right)_n}\right) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(\underbrace{b}_{\in\left(\Lambda_{\mathbb{C}}\right)_m}\right) &\in \underbrace{\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(\left(\Lambda_{\mathbb{C}}\right)_n\right)}_{=R_{\mathbb{C}}\left(\mathfrak{S}_n\right)} \otimes \underbrace{\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(\left(\Lambda_{\mathbb{C}}\right)_m\right)}_{=R_{\mathbb{C}}\left(\mathfrak{S}_m\right)} \\ &= R_{\mathbb{C}}\left(\mathfrak{S}_n\right) \otimes R_{\mathbb{C}}\left(\mathfrak{S}_m\right) = R_{\mathbb{C}}\left(\mathfrak{S}_n \times \mathfrak{S}_m\right).\end{aligned}$$

)

Choose some permutation $h \in \mathfrak{S}_m$ which has cycle type η. (Such an h clearly exists.) Then, $\operatorname{ch}_{\mathbb{C}}\left(\alpha_{\mathfrak{S}_m,h}\right) = p_\eta$ (according to (13.122.2), applied to m, h and η instead of n, g and λ). Hence, $\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(p_\eta) = \alpha_{\mathfrak{S}_m,h}$, so that $\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}\left(\underbrace{b}_{=p_\eta}\right) = \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(p_\eta) = \alpha_{\mathfrak{S}_m,h}$. Thus,

$$\underbrace{\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(a)}_{=\alpha_{\mathfrak{S}_n,g}} \otimes \underbrace{\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(b)}_{=\alpha_{\mathfrak{S}_m,h}} = \alpha_{\mathfrak{S}_n,g} \otimes \alpha_{\mathfrak{S}_m,h}. \tag{13.122.6}$$

Exercise 4.4.3(c) (applied to $G_1 = \mathfrak{S}_n$, $G_2 = \mathfrak{S}_m$, $h_1 = g$ and $h_2 = h$) yields that the canonical isomorphism $R_{\mathbb{C}}(\mathfrak{S}_n) \otimes R_{\mathbb{C}}(\mathfrak{S}_m) \to R_{\mathbb{C}}(\mathfrak{S}_n \times \mathfrak{S}_m)$ sends $\alpha_{\mathfrak{S}_n,g} \otimes \alpha_{\mathfrak{S}_m,h}$ to $\alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}$. Since we are regarding this isomorphism as an identity (because we have identified $R_{\mathbb{C}}(\mathfrak{S}_n) \otimes R_{\mathbb{C}}(\mathfrak{S}_m)$ with $R_{\mathbb{C}}(\mathfrak{S}_n \times \mathfrak{S}_m)$ along this isomorphism), this yields $\alpha_{\mathfrak{S}_n,g} \otimes \alpha_{\mathfrak{S}_m,h} = \alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}$. Thus, (13.122.6) becomes

$$\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(a) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(b) = \alpha_{\mathfrak{S}_n,g} \otimes \alpha_{\mathfrak{S}_m,h} = \alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}.$$

Applying the map τ^* to both sides of this equality, we obtain

$$\tau^*\left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(a) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(b)\right) = \tau^*\left(\alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}\right). \tag{13.122.7}$$

But $\overline{\Omega}((g,h)) = \Omega((g,h))$ (by the definition of $\overline{\Omega}((g,h))$), and so $(g,h) = \underbrace{\overline{\Omega}^{-1}}_{=\tau}(\Omega((g,h))) = \tau(\Omega((g,h)))$. Thus,

$$\tau^*\left(\alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}\right) = \tau^*\left(\alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,\tau(\Omega((g,h)))}\right) = \alpha_{\Omega(\mathfrak{S}_n \times \mathfrak{S}_m),\Omega((g,h))}$$

(by Lemma 13.122.3(d), applied to $\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)$, $\mathfrak{S}_n \times \mathfrak{S}_m$ and $\Omega((g,h))$ instead of K, H and g). Thus, (13.122.7) becomes

$$\tau^*\left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(a) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(b)\right) = \tau^*\left(\alpha_{\mathfrak{S}_n \times \mathfrak{S}_m,(g,h)}\right) = \alpha_{\Omega(\mathfrak{S}_n \times \mathfrak{S}_m),\Omega((g,h))}.$$

Applying the map $\operatorname{Ind}_{\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)}^{\mathfrak{S}_{nm}}$ to both sides of this equality, we obtain

$$\begin{aligned} \operatorname{Ind}_{\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\tau^*\left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(a) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(b)\right)\right) &= \operatorname{Ind}_{\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\alpha_{\Omega(\mathfrak{S}_n \times \mathfrak{S}_m),\Omega((g,h))}\right) \\ &= \alpha_{\mathfrak{S}_{nm},\Omega((g,h))} \end{aligned} \tag{13.122.8}$$

(by Exercise 4.4.3(b), applied to $\mathfrak{S}_{nm}$, $\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)$ and $\Omega((g,h))$ instead of G, H and h).

Now, $\Omega((g,h)) \in \mathfrak{S}_{nm}$, so that $\Omega((g,h))$ is a permutation of $\{1,2,\ldots,nm\}$. Let κ be the cycle type of this permutation $\Omega((g,h))$. Then, (13.122.2) (applied to nm, κ and $\Omega((g,h))$ instead of n, λ and g) yields $\operatorname{ch}_{\mathbb{C}}\left(\alpha_{\mathfrak{S}_{nm},\Omega((g,h))}\right) = p_\kappa$. But applying the map $\operatorname{ch}_{\mathbb{C}}$ to both sides of the identity (13.122.8), we obtain

$$\begin{aligned} &\operatorname{ch}_{\mathbb{C}}\left(\operatorname{Ind}_{\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\tau^*\left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(a) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(b)\right)\right)\right) \\ &= \operatorname{ch}_{\mathbb{C}}\left(\alpha_{\mathfrak{S}_{nm},\Omega((g,h))}\right) = p_\kappa. \end{aligned} \tag{13.122.9}$$

Let us now show that $a \boxdot b = p_\kappa$.

In fact, $\underbrace{\Omega}_{=\varphi^* \circ \operatorname{cross}}((g,h)) = (\varphi^* \circ \operatorname{cross})((g,h)) = \varphi^*\left(\underbrace{\operatorname{cross}((g,h))}_{\substack{=g \times h \\ \text{(by the definition} \\ \text{of cross)}}}\right) = \varphi^*(g \times h)$. But Lemma 13.122.5(b) (applied to $U = X \times Y$, $V = \{1,2,\ldots,nm\}$ and $\pi = g \times h$) yields that the cycle type of $\varphi^*(g \times h)$ equals the cycle type of $g \times h$. In other words, the cycle type of $\Omega((g,h))$ equals the cycle type of $g \times h$ (since $\Omega((g,h)) = \varphi^*(g \times h)$). In other words, κ equals the cycle type of $g \times h$ (since κ is the cycle type of $\Omega((g,h))$).

So we know that $g \in \mathfrak{S}_n = \mathfrak{S}_X$ and $h \in \mathfrak{S}_m = \mathfrak{S}_Y$ are permutations, and that γ, η and κ are the cycle types of the permutations g, h and $g \times h$. Thus, Lemma 13.122.2 (applied to γ and η instead of λ and μ)

yields $p_\gamma \boxdot p_\eta = p_\kappa$. Now,

$$\underbrace{a}_{=p_\gamma} \boxdot \underbrace{b}_{=p_\eta} = p_\gamma \boxdot p_\eta = p_\kappa = \operatorname{ch}_{\mathbb{C}}\left(\operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\tau^*\left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(a)\otimes\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1}(b)\right)\right)\right)$$

(by (13.122.9)). This proves (13.122.5).

Now that (13.122.5) is proven, it is easy to complete the solution of Exercise 4.4.9(c). Recall that μ and ν are two partitions such that $\mu \in \operatorname{Par}_m$, $\nu \in \operatorname{Par}_n$, $m \geq 1$ and $n \geq 1$. We need to show that $s_\mu \boxdot s_\nu \in \sum_{\lambda\in\operatorname{Par}} \mathbb{N} s_\lambda$.

Applying (13.122.3) to $\lambda = \mu$, we obtain $\operatorname{ch}_{\mathbb{C}}(\chi^\mu) = s_\mu$, so that $(\operatorname{ch}_{\mathbb{C}})^{-1}(s_\mu) = \chi^\mu$. The same argument (but with μ replaced by ν) shows that $(\operatorname{ch}_{\mathbb{C}})^{-1}(s_\nu) = \chi^\nu$.

We know that χ^μ is an irreducible complex character of $\mathbb{C}\mathfrak{S}_m$. In other words, there exists a simple $\mathbb{C}\mathfrak{S}_m$-module M such that $\chi^\mu = \chi_M$. Consider this M. Then, $(\operatorname{ch}_{\mathbb{C}})^{-1}(s_\mu) = \chi^\mu = \chi_M$.

We know that χ^ν is an irreducible complex character of $\mathbb{C}\mathfrak{S}_n$. In other words, there exists a simple $\mathbb{C}\mathfrak{S}_n$-module N such that $\chi^\nu = \chi_N$. Consider this N. Then, $(\operatorname{ch}_{\mathbb{C}})^{-1}(s_\nu) = \chi^\nu = \chi_N$.

Recall that we are identifying $R_{\mathbb{C}}(\mathfrak{S}_n) \otimes R_{\mathbb{C}}(\mathfrak{S}_m)$ with $R_{\mathbb{C}}(\mathfrak{S}_n \times \mathfrak{S}_m)$ along the canonical isomorphism $R_{\mathbb{C}}(\mathfrak{S}_n) \otimes R_{\mathbb{C}}(\mathfrak{S}_m) \to R_{\mathbb{C}}(\mathfrak{S}_n \times \mathfrak{S}_m)$. Thus, for any finite-dimensional $\mathbb{C}\mathfrak{S}_n$-module U and any finite-dimensional $\mathbb{C}\mathfrak{S}_m$-module V, we have $\chi_{U\otimes V} = \chi_U \otimes \chi_V$ (since this isomorphism sends $\chi_U \otimes \chi_V$ to $\chi_{U\otimes V}$). Applying this to $U = N$ and $V = M$, we obtain $\chi_{N\otimes M} = \chi_N \otimes \chi_M$. Thus, $\chi_N \otimes \chi_M = \chi_{N\otimes M}$.

Lemma 13.122.3(b) (applied to $\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)$, $\mathfrak{S}_n \times \mathfrak{S}_m$ and $N \otimes M$ instead of K, H and U) yields $\chi_{(N\otimes M)^\tau} = \tau^*(\chi_{N\otimes M})$. Thus, $\tau^*(\chi_{N\otimes M}) = \chi_{(N\otimes M)^\tau}$. Hence,

$$\tau^*\left(\underbrace{\chi_N \otimes \chi_M}_{=\chi_{N\otimes M}}\right) = \tau^*(\chi_{N\otimes M}) = \chi_{(N\otimes M)^\tau}. \tag{13.122.10}$$

But (4.1.5) (applied to $\mathfrak{S}_{nm}$, $\Omega(\mathfrak{S}_n \times \mathfrak{S}_m)$ and $(N\otimes M)^\tau$ instead of G, H and U) yields $\chi_{\operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}((N\otimes M)^\tau)} = \operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\chi_{(N\otimes M)^\tau}\right)$. Let P denote the finite-dimensional $\mathbb{C}\mathfrak{S}_{nm}$-module $\operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}((N\otimes M)^\tau)$. Then, $P = \operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}((N\otimes M)^\tau)$, so that

$$\chi_P = \chi_{\operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}((N\otimes M)^\tau)} = \operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\underbrace{\chi_{(N\otimes M)^\tau}}_{\substack{=\tau^*(\chi_N\otimes\chi_M)\\ (\text{by } (13.122.10))}}\right) = \operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\tau^*(\chi_N\otimes\chi_M)\right).$$

Hence,

$$\operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\tau^*(\chi_N\otimes\chi_M)\right) = \chi_P. \tag{13.122.11}$$

We have $s_\mu \in (\Lambda_{\mathbb{C}})_m$ (since $\mu \in \operatorname{Par}_m$) and $s_\nu \in (\Lambda_{\mathbb{C}})_n$ (since $\nu \in \operatorname{Par}_n$). Thus, we can apply (13.122.5) to $a = s_\nu$ and $b = s_\mu$.

Exercise 4.4.9(a) yields that $\Lambda_{\mathbb{Q}}$, equipped with the binary operation $\boxdot$, becomes a commutative $\mathbb{Q}$-algebra with unity p_1. Thus, the operation $\boxdot$ is commutative. Hence,

$$\begin{aligned} s_\mu \boxdot s_\nu = s_\nu \boxdot s_\mu &= \operatorname{ch}_{\mathbb{C}}\left(\operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\tau^*\left(\underbrace{(\operatorname{ch}_{\mathbb{C}})^{-1}(s_\nu)}_{=\chi_N}\otimes\underbrace{(\operatorname{ch}_{\mathbb{C}})^{-1}(s_\mu)}_{=\chi_M}\right)\right)\right) \\ &\qquad (\text{by } (13.122.5), \text{ applied to } a = s_\nu \text{ and } b = s_\mu) \\ &= \operatorname{ch}_{\mathbb{C}}\left(\underbrace{\operatorname{Ind}_{\Omega(\mathfrak{S}_n\times\mathfrak{S}_m)}^{\mathfrak{S}_{nm}}\left(\tau^*(\chi_N\otimes\chi_M)\right)}_{\substack{=\chi_P\\ (\text{by } (13.122.11))}}\right) = \operatorname{ch}_{\mathbb{C}}(\chi_P) \in \sum_{\lambda\in\operatorname{Par}} \mathbb{N} s_\lambda \qquad (\text{by } (13.122.4)). \end{aligned}$$

This solves Exercise 4.4.9(c).

[*Remark:* The above solution can be simplified using the results of Exercise 4.1.14. We leave the details of this simplification to the reader, and only mention some highlights. Let us use the notations of Exercise 4.1.14. Then, the awkward equality (13.122.5) can be replaced by the simpler equality

$$a \boxdot b = \operatorname{ch}_{\mathbb{C}} \left(\operatorname{Ind}_{\Omega} \left(\left(\operatorname{ch}_{\mathbb{C}}\right)^{-1} (a) \otimes \left(\operatorname{ch}_{\mathbb{C}}\right)^{-1} (b) \right) \right) . \tag{13.122.12}$$

This makes the definition of the maps $\overline{\Omega}$ and τ unnecessary. The WLOG assumption that we don't have $\min\{m, n\} = 0$ becomes unnecessary as well; the injectivity of the map cross can no longer be guaranteed without this assumption, but we do not need this map to be injective anymore. We no longer need Lemma 13.122.1(b), Lemma 13.122.3 and Lemma 13.122.4. However, we need to use Exercise 4.1.14(b) instead of (4.1.5), and we have to use Exercise 4.4.3(f) instead of Exercise 4.4.3(b).]

(d) We need to prove that $f \boxdot g \in \Lambda$ for any $f \in \Lambda$ and $g \in \Lambda$. Since the binary operation $\boxdot$ is $\mathbb{Z}$-bilinear (because it is $\mathbb{Q}$-bilinear), it is clearly enough to prove that $s_\mu \boxdot s_\nu \in \Lambda$ for any partitions μ and ν (since $(s_\lambda)_{\lambda \in \operatorname{Par}}$ is a $\mathbb{Z}$-basis of Λ). But this follows from the fact that

$$\begin{aligned} s_\mu \boxdot s_\nu &\in \sum_{\lambda \in \operatorname{Par}} \mathbb{N} s_\lambda \qquad \text{(by Exercise 4.4.9(c))} \\ &\subset \Lambda \end{aligned}$$

for any partitions μ and ν. Thus, Exercise 4.4.9(d) is solved.

13.123. **Solution to Exercise 4.6.4.** *Solution to Exercise 4.6.4.* (a) We shall prove the following fact:

Lemma 13.123.1. *Let q be a prime power. For every positive integer n, we have*

$$(\text{the number of all irreducible monic degree-}n\text{ polynomials in } \mathbb{F}_q[x]) = \frac{1}{n} \sum_{d \mid n} \mu\left(\frac{n}{d}\right) q^d .$$

Proof of Lemma 13.123.1. We first recall that every positive integer n satisfies

$$\sum_{d \mid n} \mu(d) = \delta_{n,1} . \tag{13.123.1}$$

(This is precisely the equality (13.84.3), which was proven in the solution of Exercise 2.9.6.)

For every positive integer n, define a nonnegative integer $\operatorname{irr} n$ by

$$\operatorname{irr} n = (\text{the number of all irreducible monic degree-}n\text{ polynomials in } \mathbb{F}_q[x]) . \tag{13.123.2}$$

Let $\mathfrak{P}$ denote the set of all irreducible monic polynomials in $\mathbb{F}_q[x]$. Then, every $p \in \mathfrak{P}$ is an irreducible polynomial and thus satisfies $\deg p \geq 1$. Also, the irreducible monic polynomials in $\mathbb{F}_q[x]$ are exactly the elements of $\mathfrak{P}$ (since $\mathfrak{P}$ is the set of all irreducible monic polynomials in $\mathbb{F}_q[x]$). Hence, for every positive integer n, we have

$$\begin{aligned} \operatorname{irr} n &= (\text{the number of all irreducible monic degree-}n\text{ polynomials in } \mathbb{F}_q[x]) \\ &= (\text{the number of all irreducible monic polynomials } p \text{ in } \mathbb{F}_q[x] \text{ such that } \deg p = n) \\ &= (\text{the number of all } p \in \mathfrak{P} \text{ such that } \deg p = n) \\ &\qquad (\text{since the irreducible monic polynomials in } \mathbb{F}_q[x] \text{ are exactly the elements of } \mathfrak{P}) . \end{aligned}$$

In other words, for every positive integer n, we have

$$(\text{the number of all } p \in \mathfrak{P} \text{ such that } \deg p = n) = \operatorname{irr} n . \tag{13.123.3}$$

Let $\mathfrak{N}$ be the set of all families $(k_p)_{p \in \mathfrak{P}} \in \mathbb{N}^{\mathfrak{P}}$ of nonnegative integers (indexed by the polynomials belonging to $\mathfrak{P}$) such that all but finitely many $p \in \mathfrak{P}$ satisfy $k_p = 0$. Every monic polynomial $P \in \mathbb{F}_q[x]$ has a unique factorization into irreducible monic polynomials. In other words, every monic polynomial $P \in \mathbb{F}_q[x]$ can be written in the form $P = \prod_{p\in\mathfrak{P}} p^{k_p}$ for a unique family $(k_p)_{p\in\mathfrak{P}} \in \mathfrak{N}$. Thus, the map

$$\begin{aligned} \mathfrak{N} &\to \{P \in \mathbb{F}_q[x] \mid P \text{ is monic}\}, \\ (k_p)_{p\in\mathfrak{P}} &\mapsto \prod_{p\in\mathfrak{P}} p^{k_p} \end{aligned}$$

is bijective. Thus, in the ring $\mathbb{Q}[[t]]$ of formal power series, we have

$$\sum_{\substack{P\in\mathbb{F}_q[x];\\ P \text{ is monic}}} t^{\deg P} = \sum_{(k_p)_{p\in\mathfrak{P}}\in\mathfrak{N}} t^{\deg\left(\prod_{p\in\mathfrak{P}} p^{k_p}\right)}. \tag{13.123.4}$$

But every $(k_p)_{p\in\mathfrak{P}} \in \mathfrak{N}$ satisfies

$$\begin{aligned} t^{\deg\left(\prod_{p\in\mathfrak{P}} p^{k_p}\right)} &= t^{\sum_{p\in\mathfrak{P}} k_p \deg p} \qquad \left(\text{since } \deg\left(\prod_{p\in\mathfrak{P}} p^{k_p}\right) = \sum_{p\in\mathfrak{P}} k_p \deg p\right) \\ &= \prod_{p\in\mathfrak{P}} t^{k_p \deg p} = \prod_{p\in\mathfrak{P}} \left(t^{\deg p}\right)^{k_p}. \end{aligned}$$

Thus, (13.123.4) becomes

$$\begin{aligned} \sum_{\substack{P\in\mathbb{F}_q[x];\\ P \text{ is monic}}} t^{\deg P} &= \sum_{(k_p)_{p\in\mathfrak{P}}\in\mathfrak{N}} \underbrace{t^{\deg\left(\prod_{p\in\mathfrak{P}} p^{k_p}\right)}}_{=\prod_{p\in\mathfrak{P}} \left(t^{\deg p}\right)^{k_p}} = \sum_{(k_p)_{p\in\mathfrak{P}}\in\mathfrak{N}} \prod_{p\in\mathfrak{P}} \left(t^{\deg p}\right)^{k_p} \\ &= \prod_{p\in\mathfrak{P}} \sum_{k\in\mathbb{N}} \left(t^{\deg p}\right)^{k} \qquad \text{(by the product rule)} \\ &= \prod_{n\geq 1} \prod_{\substack{p\in\mathfrak{P};\\ \deg p = n}} \sum_{k\in\mathbb{N}} \left(\underbrace{t^{\deg p}}_{\substack{=t^n \\ (\text{since } \deg p = n)}} \right)^{k} \qquad (\text{since } \deg p \geq 1 \text{ for every } p \in \mathfrak{P}) \\ &= \prod_{n\geq 1} \prod_{\substack{p\in\mathfrak{P};\\ \deg p = n}} \underbrace{\sum_{k\in\mathbb{N}} \left(t^n\right)^k}_{=\dfrac{1}{1-t^n}} = \prod_{n\geq 1} \underbrace{\underbrace{\prod_{\substack{p\in\mathfrak{P};\\ \deg p = n}} \frac{1}{1-t^n}}_{=\left(\dfrac{1}{1-t^n}\right)^{(\text{the number of all } p\in\mathfrak{P} \text{ such that } \deg p = n)}}}_{\substack{=\left(\dfrac{1}{1-t^n}\right)^{\operatorname{irr} n} \\ (\text{by (13.123.3)})}} \\ &= \prod_{n\geq 1} \left(\frac{1}{1-t^n}\right)^{\operatorname{irr} n}. \end{aligned}$$

Compared with

$$\sum_{\substack{P\in\mathbb{F}_q[x];\\ P\text{ is monic}}} t^{\deg P} = \sum_{n\in\mathbb{N}} \sum_{\substack{P\in\mathbb{F}_q[x];\\ P\text{ is monic;}\\ \deg P=n}} \underbrace{t^{\deg P}}_{\substack{=t^n\\ (\text{since }\deg P=n)}} = \sum_{n\in\mathbb{N}} \underbrace{\sum_{\substack{P\in\mathbb{F}_q[x];\\ P\text{ is monic;}\\ \deg P=n}} t^n}_{=(\text{the number of all monic }P\in\mathbb{F}_q[x]\text{ such that }\deg P=n)\cdot t^n}$$

$$= \sum_{n\in\mathbb{N}} \underbrace{(\text{the number of all monic } P\in\mathbb{F}_q[x] \text{ such that } \deg P = n)}_{\substack{=q^n\\ (\text{because specifying a monic }P\in\mathbb{F}_q[x]\text{ such that }\deg P=n\\ \text{is equivalent to specifying its coefficients before }x^0,\ x^1,\ \ldots,\ x^{n-1},\\ \text{and each of these coefficients can be chosen freely from }q\\ \text{possible values})}} \cdot t^n$$

$$= \sum_{n\in\mathbb{N}} q^n t^n = \sum_{n\in\mathbb{N}} (qt)^n = \frac{1}{1-qt},$$

this yields

$$\frac{1}{1-qt} = \prod_{n\geq 1} \left(\frac{1}{1-t^n}\right)^{\operatorname{irr} n}.$$

Taking the logarithm of both sides of this identity, we obtain

$$\log\frac{1}{1-qt} = \log\left(\prod_{n\geq 1}\left(\frac{1}{1-t^n}\right)^{\operatorname{irr} n}\right) = \sum_{n\geq 1} (\operatorname{irr} n)\cdot \underbrace{\log\left(\frac{1}{1-t^n}\right)}_{\substack{=-\log(1-t^n)=\sum_{u\geq 1}\frac{1}{u}(t^n)^u\\ (\text{by the Mercator series for the logarithm})}}$$

$$= \sum_{n\geq 1} (\operatorname{irr} n)\cdot \sum_{u\geq 1} \frac{1}{u}(t^n)^u = \sum_{n\geq 1}\sum_{u\geq 1} (\operatorname{irr} n)\frac{1}{u}\underbrace{(t^n)^u}_{=t^{nu}} = \sum_{n\geq 1}\sum_{u\geq 1}(\operatorname{irr} n)\frac{1}{u}t^{nu}$$

$$= \underbrace{\sum_{n\geq 1}\sum_{\substack{v\geq 1;\\ n\mid v}}}_{=\sum_{v\geq 1}\sum_{n\mid v}} (\operatorname{irr} n)\underbrace{\frac{1}{v/n}}_{=\frac{n}{v}} t^v \qquad (\text{here, we substituted } v/n \text{ for } u \text{ in the second sum})$$

$$= \sum_{v\geq 1}\sum_{n\mid v}(\operatorname{irr} n)\frac{n}{v}t^v = \sum_{n\geq 1}\sum_{d\mid n}(\operatorname{irr} d)\frac{d}{n}t^n$$

(here, we renamed the summation indices v and n as n and d). Since

$$\log\frac{1}{1-qt} = -\log(1-qt) = \sum_{n\geq 1}\frac{1}{n}(qt)^n \qquad (\text{by the Mercator series for the logarithm})$$
$$= \sum_{n\geq 1}\frac{1}{n}q^n t^n,$$

this rewrites as

$$\sum_{n\geq 1}\frac{1}{n}q^n t^n = \sum_{n\geq 1}\sum_{d\mid n}(\operatorname{irr} d)\frac{d}{n}t^n.$$

Comparing coefficients, we conclude that every positive integer n satisfies

$$\frac{1}{n}q^n = \sum_{d\mid n}(\operatorname{irr} d)\frac{d}{n}.$$

Multiplying this with n, we obtain

$$q^n = \sum_{d\mid n}(\operatorname{irr} d)\, d. \tag{13.123.5}$$

Now, every positive integer n satisfies

$$\begin{aligned}\sum_{d|n}\mu(d)\,q^{n/d} &= \sum_{e|n}\mu(e)\underbrace{q^{n/e}}_{\substack{=\sum_{d|n/e}(\operatorname{irr} d)d \\ \text{(by (13.123.5), applied} \\ \text{to } n/e \text{ instead of } n)}} = \sum_{e|n}\mu(e)\sum_{d|n/e}(\operatorname{irr} d)\,d \\ &= \underbrace{\sum_{e|n}\sum_{d|n/e}}_{=\sum_{d|n}\sum_{e|n/d}}\mu(e)(\operatorname{irr} d)\,d = \sum_{d|n}\underbrace{\sum_{e|n/d}\mu(e)}_{\substack{=\delta_{n/d,1} \\ \text{(by (13.123.1), applied} \\ \text{to } n/d \text{ instead of } n)}}(\operatorname{irr} d)\,d \\ &= \sum_{d|n}\underbrace{\delta_{n/d,1}}_{=\delta_{n,d}}(\operatorname{irr} d)\,d = \sum_{d|n}\delta_{n,d}(\operatorname{irr} d)\,d = (\operatorname{irr} n)\,n.\end{aligned}$$

Dividing this by n, we obtain $\frac{1}{n}\sum_{d|n}\mu(d)\,q^{n/d} = \operatorname{irr} n$. Now, (13.123.2) yields

$$(\text{the number of all irreducible monic degree-}n\text{ polynomials in }\mathbb{F}_q[x]) = \operatorname{irr} n = \frac{1}{n}\sum_{d|n}\mu(d)\,q^{n/d}.$$

This proves Lemma 13.123.1. □

Now, let us solve Exercise 4.6.4(a). Let $n \geq 2$ be an integer. We know that $|\mathcal{F}_n|$ is the number of irreducible monic degree-n polynomials $f(x) \neq x$ in $\mathbb{F}_q[x]$ with nonzero constant term. Since the irreducible monic degree-n polynomials $f(x) \neq x$ in $\mathbb{F}_q[x]$ with nonzero constant term are precisely the irreducible monic degree-n polynomials in $\mathbb{F}_q[x]$ [895], this statement rewrites as follows: $|\mathcal{F}_n|$ is the number of irreducible monic degree-n polynomials in $\mathbb{F}_q[x]$. In other words,

$$\begin{aligned}|\mathcal{F}_n| &= (\text{the number of all irreducible monic degree-}n\text{ polynomials in }\mathbb{F}_q[x]) \\ &= \frac{1}{n}\sum_{d|n}\mu\left(\frac{n}{d}\right)q^d \qquad \text{(by Lemma 13.123.1)}.\end{aligned}$$

This solves Exercise 4.6.4(a).

(b) We shall use the results of Exercise 6.1.34 (which provides a more systematic introduction to necklaces).

Let $\mathfrak{A}$ be the set $\mathbb{F}_q$. Consider the notion of an n-necklace defined in Exercise 6.1.34. The "n-necklaces" (as defined in Exercise 6.1.34) are precisely the "necklaces with n beads of q colors" (as defined in Exercise 4.6.4(b))[896]. Moreover, it is easy to see that the "aperiodic n-necklaces" (as defined in Exercise 6.1.34) are

[895] *Proof.* Let f be an irreducible polynomial monic degree-n polynomial in $\mathbb{F}_q[x]$. We will now show that $f(x) \neq x$ and that f has nonzero constant term.

Since f is a degree-n polynomial, we have $\deg f = n \geq 2 > 1 = \deg x$, thus $\deg f \neq \deg x$ and therefore $f \neq x$. In other words, $f(x) \neq x$.

Now, let us assume (for the sake of contradiction) that the constant term of f is zero. Then, the polynomial x divides f in $\mathbb{F}_q[x]$. But since f is irreducible, the polynomial f is a scalar multiple of every non-constant polynomial which divides f. In particular, f is a scalar multiple of x (since x is a non-constant polynomial which divides f). Consequently, $\deg f = \deg x$, which contradicts $\deg f \neq \deg x$. This contradiction proves that our assumption (that the constant term of f is zero) was wrong. Hence, the constant term of f is nonzero. In other words, f has nonzero constant term.

Now, let us forget that we fixed f. We thus have proven that every irreducible monic degree-n polynomial f in $\mathbb{F}_q[x]$ satisfies $f(x) \neq x$ and has nonzero constant term. Thus, all irreducible monic degree-n polynomials in $\mathbb{F}_q[x]$ are irreducible monic degree-n polynomials $f(x) \neq x$ in $\mathbb{F}_q[x]$ with nonzero constant term. Combining this statement with the (obvious) converse statement (which states that all irreducible monic degree-n polynomials $f(x) \neq x$ in $\mathbb{F}_q[x]$ with nonzero constant term are irreducible monic degree-n polynomials in $\mathbb{F}_q[x]$), we conclude that the irreducible monic degree-n polynomials $f(x) \neq x$ in $\mathbb{F}_q[x]$ with nonzero constant term are precisely the irreducible monic degree-n polynomials in $\mathbb{F}_q[x]$. Qed.

[896] *Proof.* Consider the group C, its generator c and the action of C on $\mathfrak{A}^n$ which are defined in Exercise 6.1.34. Then, the "n-necklaces" (as defined in Exercise 6.1.34) are the orbits of the C-action on $\mathfrak{A}^n$. In other words, the "n-necklaces" (as defined in Exercise 6.1.34) are the equivalence classes of n-tuples $(a_1, a_2, ..., a_n) \in \mathfrak{A}^n$ with respect to cyclic rotation (because C acts on $\mathfrak{A}^n$ by cyclic rotation). But the same can be said about the "necklaces with n beads of q colors" (as defined in Exercise 4.6.4(b)). Thus, the "n-necklaces" (as defined in Exercise 6.1.34) are precisely the "necklaces with n beads of q colors" (as defined in Exercise 4.6.4(b)), qed.

precisely the "primitive necklaces with n beads of q colors" (as defined in Exercise 4.6.4(b))[897]. Hence,

$$\begin{aligned}&(\text{the number of all aperiodic } n\text{-necklaces})\\&= (\text{the number of all primitive necklaces with } n \text{ beads of } q \text{ colors}),\end{aligned}$$

so that

$$\begin{aligned}&(\text{the number of all primitive necklaces with } n \text{ beads of } q \text{ colors})\\&= (\text{the number of all aperiodic } n\text{-necklaces}) = \frac{1}{n}\sum_{d\mid n}\mu\left(d\right)\underbrace{\left|\mathfrak{A}\right|^{n/d}}_{\substack{=q^{n/d}\\ (\text{since } \left|\mathfrak{A}\right|=q)}} \qquad (\text{by Exercise 6.1.34(f)})\\&= \frac{1}{n}\sum_{d\mid n}\mu\left(d\right)q^{n/d}.\end{aligned}$$

This solves Exercise 4.6.4(b).

13.124. **Solution to Exercise 4.9.6.** *Solution to Exercise 4.9.6.* Let us first notice that any $k \in \mathbb{N}$ and any k partitions $\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}$ satisfy

$$\underline{1}_{J_{\lambda^{(1)}}}\underline{1}_{J_{\lambda^{(2)}}}\cdots\underline{1}_{J_{\lambda^{(k)}}} = \sum_{\lambda\in\operatorname{Par}} g^{\lambda}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k)}}\left(q\right)\underline{1}_{J_\lambda} = \sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k)}}\left(q\right)\underline{1}_{J_\mu} \tag{13.124.1}$$

(here, we renamed the summation index λ as μ). Any two partitions μ and ν satisfy

$$\underline{1}_{J_\mu}\underline{1}_{J_\nu} = \sum_{\lambda\in\operatorname{Par}} g^{\lambda}_{\mu,\nu}\left(q\right)\underline{1}_{J_\lambda} = \sum_{\tau\in\operatorname{Par}} g^{\tau}_{\mu,\nu}\left(q\right)\underline{1}_{J_\tau} \tag{13.124.2}$$

(here, we renamed the summation index λ as τ).

(a) We shall prove the statement of Exercise 4.9.6(a) by induction over k. The base cases ($k = 0$ and $k = 1$) are left to the reader. We will now handle the induction step. So let us solve Exercise 4.9.6(a) for some positive integer $k > 1$, assuming (as the induction hypothesis) that Exercise 4.9.6(a) is already solved for $k - 1$ instead of k.

From (13.124.1), we obtain

$$\begin{aligned}&\sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k)}}\left(q\right)\underline{1}_{J_\mu}\\&= \underline{1}_{J_{\lambda^{(1)}}}\underline{1}_{J_{\lambda^{(2)}}}\cdots\underline{1}_{J_{\lambda^{(k)}}} = \underbrace{\underline{1}_{J_{\lambda^{(1)}}}\underline{1}_{J_{\lambda^{(2)}}}\cdots\underline{1}_{J_{\lambda^{(k-1)}}}}_{\substack{=\sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}(q)\underline{1}_{J_\mu}\\ (\text{by (13.124.1), applied to } k-1 \text{ instead of } k)}}\cdot\underline{1}_{J_{\lambda^{(k)}}}\\&= \left(\sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}\left(q\right)\underline{1}_{J_\mu}\right)\cdot\underline{1}_{J_{\lambda^{(k)}}} = \sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}\left(q\right)\underbrace{\underline{1}_{J_\mu}\underline{1}_{J_{\lambda^{(k)}}}}_{\substack{=\sum_{\tau\in\operatorname{Par}} g^{\tau}_{\mu,\lambda^{(k)}}(q)\underline{1}_{J_\tau}\\ (\text{by (13.124.2), applied to } \nu=\lambda^{(k)})}}\\&= \sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}\left(q\right)\sum_{\tau\in\operatorname{Par}} g^{\tau}_{\mu,\lambda^{(k)}}\left(q\right)\underline{1}_{J_\tau} = \sum_{\tau\in\operatorname{Par}}\sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}\left(q\right)g^{\tau}_{\mu,\lambda^{(k)}}\left(q\right)\underline{1}_{J_\tau}.\end{aligned}$$

Comparing coefficients in front of $\underline{1}_{J_\lambda}$ on both sides of this equality, we obtain

$$g^{\lambda}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k)}}\left(q\right) = \sum_{\mu\in\operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}\left(q\right)g^{\lambda}_{\mu,\lambda^{(k)}}\left(q\right). \tag{13.124.3}$$

Our $\mathbb{F}_q$-vector space V is n-dimensional. Hence, we can WLOG assume that $V = \mathbb{F}_q^n$ (because nothing changes if we map V isomorphically to $\mathbb{F}_q^n$ and change g accordingly). Assume this.

[897] This follows from Exercise 6.1.34(b) (because for an n-tuple $(w_1, w_2, ..., w_n) \in \mathfrak{A}^n$, the statement that no nontrivial rotation (in $\mathbb{Z}/n\mathbb{Z}$) fixes w is equivalent to the statement that every $k \in \{1, 2, \ldots, n-1\}$ satisfies $(w_{k+1}, w_{k+2}, \ldots, w_n, w_1, w_2, \ldots, w_k) \neq w$).

In the following, an *ender* will mean a g-stable $\mathbb{F}_q$-vector subspace $W \subset \mathbb{F}_q^n$ for which the induced map $\bar{g}$ on the quotient space $\mathbb{F}_q^n / W$ has Jordan type $\lambda^{(k)}$. Notice that if $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_k = V$ is a $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$-compatible g-flag, then V_{k-1} is an ender (because the definition of a $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$-compatible g-flag shows that the endomorphism of $\underbrace{\mathbb{F}_q^n}_{=V=V_k} / V_{k-1} = V_k / V_{k-1}$ induced by g has Jordan type $\lambda^{(k)}$). (This is why we have chosen the name "ender" – an ender is the last proper subspace in a $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$-compatible g-flag.)

Whenever h is a unipotent endomorphism of a finite-dimensional vector space, we let $\operatorname{type} h$ denote the Jordan type of h.

Proposition 4.9.4 (applied to $\nu = \lambda^{(k)}$) yields that for every $\mu \in \operatorname{Par}$, the number $g^{\lambda}_{\mu, \lambda^{(k)}}(q)$ counts the g-stable $\mathbb{F}_q$-subspaces $W \subset \mathbb{F}_q^n$ for which the restriction $g|W$ acts with Jordan type μ, and the induced map $\bar{g}$ on the quotient space $\mathbb{F}_q^n / W$ has Jordan type $\lambda^{(k)}$ [898]. In other words, for every $\mu \in \operatorname{Par}$, the number $g^{\lambda}_{\mu, \lambda^{(k)}}(q)$ counts the enders W for which the restriction $g|W$ acts with Jordan type μ. In other words, for every $\mu \in \operatorname{Par}$, the number $g^{\lambda}_{\mu, \lambda^{(k)}}(q)$ counts the enders W for which $\operatorname{type}(g|W) = \mu$. In other words, for every $\mu \in \operatorname{Par}$, we have

$$g^{\lambda}_{\mu, \lambda^{(k)}}(q) = \sum_{\substack{W \text{ is an ender;} \\ \operatorname{type}(g|W) = \mu}} 1.$$

Hence, (13.124.3) becomes

$$g^{\lambda}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}}(q) = \sum_{\mu \in \operatorname{Par}} g^{\mu}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}}(q) \underbrace{g^{\lambda}_{\mu, \lambda^{(k)}}(q)}_{= \sum_{\substack{W \text{ is an ender;} \\ \operatorname{type}(g|W) = \mu}} 1} = \sum_{\mu \in \operatorname{Par}} g^{\mu}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}}(q) \sum_{\substack{W \text{ is an ender;} \\ \operatorname{type}(g|W) = \mu}} 1$$

$$= \sum_{\mu \in \operatorname{Par}} \sum_{\substack{W \text{ is an ender;} \\ \operatorname{type}(g|W) = \mu}} g^{\mu}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}}(q) = \sum_{W \text{ is an ender}} g^{\operatorname{type}(g|W)}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}}(q). \tag{13.124.4}$$

Now, let us fix an ender W. By the definition of an ender, this W is a g-stable $\mathbb{F}_q$-subspace of $\mathbb{F}_q^n$ for which the induced map $\bar{g}$ on the quotient space $\mathbb{F}_q^n / W$ has Jordan type $\lambda^{(k)}$. Let $m = \dim W$.

By the induction hypothesis, we can apply Exercise 4.9.6(a) to $\operatorname{type}(g|W)$, m, W, $g|W$, $k-1$ and $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}\right)$ instead of λ, n, V, g, k and $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$. As a result, we conclude that

$$g^{\operatorname{type}(g|W)}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}}(q) \text{ is the number of } \left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}\right)\text{-compatible } g|W\text{-flags.} \tag{13.124.5}$$

Now, forget that we fixed W. Combining (13.124.4) with (13.124.5), we see that $g^{\lambda}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}}(q)$ is the number of all pairs $(W, \mathbf{F})$, where W is an ender and $\mathbf{F}$ is a $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}\right)$-compatible $g|W$-flag. But (in order to complete the induction step) we have to prove that $g^{\lambda}_{\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}}(q)$ is the number of $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$-compatible g-flags. So an obvious way to prove this would be to find a bijection between $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$-compatible g-flags and pairs $(W, \mathbf{F})$, where W is an ender and $\mathbf{F}$ is a $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}\right)$-compatible $g|W$-flag. This bijection is very easy to define: It sends a $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$-compatible g-flag $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_k = V$ to the pair $(V_{k-1}, \mathbf{F})$, where $\mathbf{F}$ is the $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}\right)$-compatible $g|V_{k-1}$-flag $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_{k-1} = V_{k-1}$. Showing that this bijection is well-defined and bijective is completely straightforward[899]; thus, the induction step is complete, and the solution of Exercise 4.9.6(a) is finished.

(b) We shall prove the statement of Exercise 4.9.6(b) by induction over k. The base cases ($k = 0$ and $k = 1$) are left to the reader. We will now handle the induction step. So let us solve Exercise 4.9.6(b) for some positive integer $k > 1$, assuming (as the induction hypothesis) that Exercise 4.9.6(b) is already solved for $k - 1$ instead of k.

[898] Note that the variable that I am calling W here has been denoted by V in Proposition 4.9.4.

[899] The inverse map takes a pair $(W, \mathbf{F})$, where W is an ender and $\mathbf{F}$ is a $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k-1)}\right)$-compatible $g|W$-flag $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_{k-1} = W$, and maps it to the $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$-compatible g-flag $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_{k-1} \subset V = V$.

We need to prove that $g^{\lambda}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k)}}(q) = 0$ unless $\left|\lambda^{(1)}\right| + \left|\lambda^{(2)}\right| + \cdots + \left|\lambda^{(k)}\right| = |\lambda|$ and $\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k)} \triangleright \lambda$. In other words, we need to prove that if $g^{\lambda}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k)}}(q) \neq 0$, then

$$\left|\lambda^{(1)}\right| + \left|\lambda^{(2)}\right| + \cdots + \left|\lambda^{(k)}\right| = |\lambda| \qquad \text{and} \qquad \lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k)} \triangleright \lambda. \tag{13.124.6}$$

So let us assume that $g^{\lambda}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k)}}(q) \neq 0$. Due to (13.124.3), this rewrites as

$$\sum_{\mu \in \operatorname{Par}} g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}(q)\, g^{\lambda}_{\mu,\lambda^{(k)}}(q) \neq 0.$$

Hence, there exists a $\mu \in \operatorname{Par}$ satisfying $g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}(q) \neq 0$ and $g^{\lambda}_{\mu,\lambda^{(k)}}(q) \neq 0$. Consider this μ.

By the induction hypothesis, we can apply Exercise 4.9.6(b) to μ, $k-1$ and $\left(\lambda^{(1)}, \lambda^{(2)}, ..., \lambda^{(k-1)}\right)$ instead of λ, k and $\left(\lambda^{(1)}, \lambda^{(2)}, \ldots, \lambda^{(k)}\right)$. Thus, we conclude that $g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}(q) = 0$ unless $\left|\lambda^{(1)}\right| + \left|\lambda^{(2)}\right| + \cdots + \left|\lambda^{(k-1)}\right| = |\mu|$ and $\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k-1)} \triangleright \mu$. Since we have $g^{\mu}_{\lambda^{(1)},\lambda^{(2)},\ldots,\lambda^{(k-1)}}(q) \neq 0$, we therefore must have $\left|\lambda^{(1)}\right| + \left|\lambda^{(2)}\right| + \cdots + \left|\lambda^{(k-1)}\right| = |\mu|$ and $\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k-1)} \triangleright \mu$.

But let $n = |\lambda|$. Fix a unipotent endomorphism g of $\mathbb{F}_q^n$ having Jordan type λ (such a g clearly exists). The number $g^{\lambda}_{\mu,\lambda^{(k)}}(q)$ counts the g-stable $\mathbb{F}_q$-subspaces $W \subset \mathbb{F}_q^n$ for which the restriction $g|W$ acts with Jordan type μ, and the induced map $\bar{g}$ on the quotient space $\mathbb{F}_q^n/W$ has Jordan type $\lambda^{(k)}$ (by Proposition 4.9.4, applied to $\nu = \lambda^{(k)}$). Since $g^{\lambda}_{\mu,\lambda^{(k)}}(q) \neq 0$, this yields that there exists such a subspace W. If we define a nilpotent endomorphism f of $\mathbb{F}_q^n$ by $f = g - \operatorname{id}_{\mathbb{F}_q^n}$ (this is indeed nilpotent because g is unipotent), then this W is also an f-stable $\mathbb{F}_q$-subspace of $\mathbb{F}_q^n$ (because any g-stable subspace of $\mathbb{F}_q^n$ is f-stable) for which the restriction $f|W$ acts with Jordan type μ (since $f|W = g|W - \operatorname{id}_W$), and the induced map $\overline{f}$ on the quotient space $\mathbb{F}_q^n/W$ has Jordan type $\lambda^{(k)}$ (since $\overline{f} = \overline{g} - \operatorname{id}_{\mathbb{F}_q^n/W}$). Therefore, Exercise 2.9.22(b) (applied to $\mathbb{K} = \mathbb{F}_q$, $V = \mathbb{F}_q^n$, $U = W$ and $\nu = \lambda^{(k)}$) yields $c^{\lambda}_{\mu,\lambda^{(k)}} \neq 0$. Consequently, $|\lambda| = |\mu| + \left|\lambda^{(k)}\right|$. Exercise 2.9.17(c) (applied to $|\lambda|$, $|\mu|$ and $\lambda^{(k)}$ instead of n, k and ν) thus yields $\mu + \lambda^{(k)} \triangleright \lambda \triangleright \mu \sqcup \lambda^{(k)}$.

Exercise 2.9.17(d) (applied to $|\mu|$, $\left|\lambda^{(k)}\right|$, $\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k-1)}$, μ, $\lambda^{(k)}$ and $\lambda^{(k)}$ instead of n, m, α, β, γ and δ) yields

$$\left(\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k-1)}\right) + \lambda^{(k)} \triangleright \mu + \lambda^{(k)}$$

(since $\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k-1)} \triangleright \mu$ and $\lambda^{(k)} \triangleright \lambda^{(k)}$).

Now,

$$\left|\lambda^{(1)}\right| + \left|\lambda^{(2)}\right| + \cdots + \left|\lambda^{(k)}\right| = \underbrace{\left|\lambda^{(1)}\right| + \left|\lambda^{(2)}\right| + \cdots + \left|\lambda^{(k-1)}\right|}_{=|\mu|} + \left|\lambda^{(k)}\right| = |\mu| + \left|\lambda^{(k)}\right| = |\lambda|$$

and

$$\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k)} = \left(\lambda^{(1)} + \lambda^{(2)} + \cdots + \lambda^{(k-1)}\right) + \lambda^{(k)} \triangleright \mu + \lambda^{(k)} \triangleright \lambda.$$

Thus, we have proven (13.124.6), and so the induction step is complete. We thus have solved Exercise 4.9.6(b).

(c) Let $n = |\lambda|$. Fix a unipotent endomorphism g of $\mathbb{F}_q^n$ having Jordan type λ (such a g clearly exists).

Exercise 4.9.6(a) (applied to $V = \mathbb{F}_q^n$, $k = \ell$ and $\lambda^{(i)} = \left(1^{(\lambda^t)_i}\right)$) shows that $g^{\lambda}_{\left(1^{(\lambda^t)_1}\right),\left(1^{(\lambda^t)_2}\right),\ldots,\left(1^{(\lambda^t)_\ell}\right)}(q)$ is the number of $\left(\left(1^{(\lambda^t)_1}\right), \left(1^{(\lambda^t)_2}\right), \ldots, \left(1^{(\lambda^t)_\ell}\right)\right)$-compatible g-flags. Hence, in order to prove $g^{\lambda}_{\left(1^{(\lambda^t)_1}\right),\left(1^{(\lambda^t)_2}\right),\ldots,\left(1^{(\lambda^t)_\ell}\right)}(q) \neq 0$ (and thus, to solve Exercise 4.9.6(c)), it will be enough to prove that there exists at least one $\left(\left(1^{(\lambda^t)_1}\right), \left(1^{(\lambda^t)_2}\right), \ldots, \left(1^{(\lambda^t)_\ell}\right)\right)$-compatible g-flag.

Let $f = g - \operatorname{id}_{\mathbb{F}_q^n}$. Then, f is a nilpotent endomorphism of $\mathbb{F}_q^n$ having Jordan type λ (since g is a unipotent endomorphism of $\mathbb{F}_q^n$ having Jordan type λ). Also, $g = f + \operatorname{id}_{\mathbb{F}_q^n}$ (since $f = g - \operatorname{id}_{\mathbb{F}_q^n}$).

Let us define a sequence $V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_\ell$ of $\mathbb{F}_q$-vector subspaces of $\mathbb{F}_q^n$ by setting

$$V_i = \ker\left(f^i\right) \qquad \text{for every } i \in \{0, 1, ..., \ell\}.$$

Then, $V_0 = \ker \left(\underbrace{f^0}_{=\mathrm{id}} \right) = \ker \mathrm{id} = 0$. Also, it follows readily from Exercise 2.9.22(a) that

$$\dim \left(\ker \left(f^k \right) \right) = \left(\lambda^t \right)_1 + \left(\lambda^t \right)_2 + \ldots + \left(\lambda^t \right)_k \qquad \text{for every } k \in \mathbb{N}. \tag{13.124.7}$$

[900] Applying this to $k = \ell$, we obtain

$$\begin{aligned} \dim \left(\ker \left(f^\ell \right) \right) &= \left(\lambda^t \right)_1 + \left(\lambda^t \right)_2 + \ldots + \left(\lambda^t \right)_\ell = \left| \lambda^t \right| \qquad \left(\text{since } \lambda^t = \left(\left(\lambda^t \right)_1, \left(\lambda^t \right)_2, \ldots, \left(\lambda^t \right)_\ell \right) \right) \\ &= |\lambda| = n = \dim \left(\mathbb{F}_q^n \right) \end{aligned}$$

which yields $\ker \left(f^\ell \right) = \mathbb{F}_q^n$ (since $\ker \left(f^\ell \right) \subset \mathbb{F}_q^n$). Thus, $V_\ell = \ker \left(f^\ell \right) = \mathbb{F}_q^n$. Since $V_0 = 0$ and $V_\ell = \mathbb{F}_q^n$, our sequence $V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_\ell$ thus can be written as $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_\ell = \mathbb{F}_q^n$.

For every $i \in \{0, 1, ..., \ell\}$, the $\mathbb{F}_q$-vector subspace V_i of $\mathbb{F}_q^n$ is g-invariant (since $V_i = \ker \left(f^i \right)$ is f-invariant and thus g-invariant). Also, for every $i \in \{1, 2, ..., \ell\}$, we have $\underbrace{V_i}_{=\ker(f^i)} / \underbrace{V_{i-1}}_{=\ker(f^{i-1})} = \ker \left(f^i \right) / \ker \left(f^{i-1} \right)$; thus, the endomorphism of V_i / V_{i-1} induced by f is the zero map, and therefore the endomorphism of V_i / V_{i-1} induced by g is the identity map (since $g = f + \mathrm{id}_{\mathbb{F}_q^n}$). Hence, for every $i \in \{1, 2, ..., \ell\}$, this latter endomorphism has Jordan type $\left(1^{\dim(V_i / V_{i-1})} \right)$. But since every $i \in \{1, 2, ..., \ell\}$ satisfies

$$\begin{aligned} \dim \left(\underbrace{V_i / V_{i-1}}_{=\ker(f^i) / \ker(f^{i-1})} \right) &= \dim \left(\ker \left(f^i \right) / \ker \left(f^{i-1} \right) \right) = \underbrace{\dim \left(\ker \left(f^i \right) \right)}_{\substack{=(\lambda^t)_1 + (\lambda^t)_2 + \ldots + (\lambda^t)_i \\ \text{(by (13.124.7),} \\ \text{applied to } k=i)}} - \underbrace{\dim \left(\ker \left(f^{i-1} \right) \right)}_{\substack{=(\lambda^t)_1 + (\lambda^t)_2 + \ldots + (\lambda^t)_{i-1} \\ \text{(by (13.124.7),} \\ \text{applied to } k=i-1)}} \\ &= \left(\left(\lambda^t \right)_1 + \left(\lambda^t \right)_2 + \ldots + \left(\lambda^t \right)_i \right) - \left(\left(\lambda^t \right)_1 + \left(\lambda^t \right)_2 + \ldots + \left(\lambda^t \right)_{i-1} \right) = \left(\lambda^t \right)_i, \end{aligned}$$

this rewrites as follows: For every $i \in \{1, 2, ..., \ell\}$, the endomorphism of V_i / V_{i-1} induced by g has Jordan type $\left(1^{(\lambda^t)_i} \right)$.

Altogether, we now know that $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_\ell = \mathbb{F}_q^n$ is a sequence of g-invariant $\mathbb{F}_q$-vector subspaces V_i of $\mathbb{F}_q^n$ such that for every $i \in \{1, 2, \ldots, \ell\}$, the endomorphism of V_i / V_{i-1} induced by g has Jordan type $\left(1^{(\lambda^t)_i} \right)$. In other words, $0 = V_0 \subset V_1 \subset V_2 \subset \cdots \subset V_\ell = \mathbb{F}_q^n$ is a $\left(\left(1^{(\lambda^t)_1} \right), \left(1^{(\lambda^t)_2} \right), \ldots, \left(1^{(\lambda^t)_\ell} \right) \right)$-compatible g-flag (according the definition of the latter notion). Hence, there exists at least one $\left(\left(1^{(\lambda^t)_1} \right), \left(1^{(\lambda^t)_2} \right), \ldots, \left(1^{(\lambda^t)_\ell} \right) \right)$-compatible g-flag. Exercise 4.9.6(c) is solved.

(d) Write the partition λ as $\lambda = (\lambda_1, \lambda_2, ..., \lambda_\ell)$ with $\ell = \ell(\lambda)$. Then, $\left(\lambda^t \right)^t = \lambda = (\lambda_1, \lambda_2, ..., \lambda_\ell)$. Hence, Exercise 4.9.6(c) (applied to λ^t instead of λ) yields

$$g^{\lambda^t}_{(1^{\lambda_1}), (1^{\lambda_2}), \ldots, (1^{\lambda_\ell})}(q) \neq 0. \tag{13.124.8}$$

[900] *Proof of (13.124.7):* Let $k \in \mathbb{N}$. Let $N \in \mathbb{F}_q^{n \times n}$ be the matrix representing the endomorphism f of $\mathbb{F}_q^n$. Then, N is nilpotent (since f is nilpotent) and has Jordan type λ (since f has Jordan type λ), and thus satisfies $\dim \left(\ker \left(N^k \right) \right) = \left(\lambda^t \right)_1 + \left(\lambda^t \right)_2 + \ldots + \left(\lambda^t \right)_k$ (by Exercise 2.9.22(a)). But since N is a matrix representing the map f, we have $\dim \left(\ker \left(N^k \right) \right) = \dim \left(\ker \left(f^k \right) \right)$, so that $\dim \left(\ker \left(f^k \right) \right) = \dim \left(\ker \left(N^k \right) \right) = \left(\lambda^t \right)_1 + \left(\lambda^t \right)_2 + \ldots + \left(\lambda^t \right)_k$. This proves (13.124.7).

But since $\lambda = (\lambda_1, \lambda_2, ..., \lambda_\ell)$, we have $e_\lambda = e_{\lambda_1} e_{\lambda_2} \cdots e_{\lambda_\ell}$ and thus

$$\begin{aligned}
\varphi(e_\lambda) &= \varphi(e_{\lambda_1} e_{\lambda_2} \cdots e_{\lambda_\ell}) \\
&= \varphi(e_{\lambda_1}) \varphi(e_{\lambda_2}) \cdots \varphi(e_{\lambda_\ell}) \qquad (\text{since } \varphi \text{ is a } \mathbb{C}\text{-algebra homomorphism}) \\
&= \prod_{i=1}^{\ell} \underbrace{\varphi(e_{\lambda_i})}_{\substack{= q^{\binom{\lambda_i}{2}} \underline{1}_{J_{(1^{\lambda_i})}} \\ (\text{since Theorem 4.9.5 yields} \\ \varphi(e_p) = q^{\binom{p}{2}} \underline{1}_{J_{(1^p)}} \text{ for every } p \in \mathbb{N})}} = \prod_{i=1}^{\ell} \left(q^{\binom{\lambda_i}{2}} \underline{1}_{J_{(1^{\lambda_i})}} \right) \\
&= \left(\prod_{i=1}^{\ell} q^{\binom{\lambda_i}{2}} \right) \underbrace{\prod_{i=1}^{\ell} \underline{1}_{J_{(1^{\lambda_i})}}}_{\substack{= \underline{1}_{J_{(1^{\lambda_1})}} \underline{1}_{J_{(1^{\lambda_2})}} \cdots \underline{1}_{J_{(1^{\lambda_\ell})}} \\ = \sum_{\mu \in \operatorname{Par}} g^{\mu}_{(1^{\lambda_1}), (1^{\lambda_2}), ..., (1^{\lambda_\ell})}(q) \underline{1}_{J_\mu} \\ (\text{by (13.124.1), applied to } k = \ell \text{ and } \lambda^{(i)} = (1^{\lambda_i}))}} \\
&= \left(\prod_{i=1}^{\ell} q^{\binom{\lambda_i}{2}} \right) \sum_{\mu \in \operatorname{Par}} g^{\mu}_{(1^{\lambda_1}), (1^{\lambda_2}), ..., (1^{\lambda_\ell})}(q) \underline{1}_{J_\mu}. \qquad (13.124.9)
\end{aligned}$$

Now, we notice that

$$\lambda^t = (1^{\lambda_1}) + (1^{\lambda_2}) + \cdots + (1^{\lambda_\ell}) \qquad (13.124.10)$$

[901]. Now, for every partition μ, we have $g^{\mu}_{(1^{\lambda_1}), (1^{\lambda_2}), ..., (1^{\lambda_\ell})}(q) = 0$ unless $\mu \in \operatorname{Par}_n$ and $\lambda^t \triangleright \mu$ [902]. Hence, we can replace the summation sign "$\sum_{\mu \in \operatorname{Par}}$" on the right hand side of (13.124.9) by a more restricted

[901] *Proof of (13.124.10):* In the following, we use the so-called *Iverson bracket notation*: For every assertion $\mathcal{A}$, we let $[\mathcal{A}]$ denote the integer $\begin{cases} 1, & \text{if } \mathcal{A} \text{ is true;} \\ 0, & \text{if } \mathcal{A} \text{ is false} \end{cases}$. (This integer is called the *truth value* of $\mathcal{A}$.)

For every $p \in \mathbb{N}$ and $i \in \{1, 2, 3, ...\}$, we have

$$(1^p)_i = [p \geq i]. \qquad (13.124.11)$$

Now, every $i \in \{1, 2, 3, ...\}$ satisfies

$$\begin{aligned}
\left((1^{\lambda_1}) + (1^{\lambda_2}) + \cdots + (1^{\lambda_\ell}) \right)_i &= (1^{\lambda_1})_i + (1^{\lambda_2})_i + \cdots + (1^{\lambda_\ell})_i \qquad (\text{by the definition of } \mu + \nu \text{ for two partitions } \mu \text{ and } \nu) \\
&= \sum_{k=1}^{\ell} \underbrace{(1^{\lambda_k})_i}_{\substack{= [\lambda_k \geq i] \\ (\text{by (13.124.11)})}} = \sum_{k=1}^{\ell} [\lambda_k \geq i] \\
&= |\{j \in \{1, 2, ..., \ell\} \mid \lambda_j \geq i\}| = (\lambda^t)_i \qquad (\text{by (2.2.7)}).
\end{aligned}$$

Hence, $(1^{\lambda_1}) + (1^{\lambda_2}) + \cdots + (1^{\lambda_\ell}) = \lambda^t$, qed.

[902] *Proof.* Let μ be a partition. Exercise 4.9.6(b) (applied to ℓ, (1^{λ_i}) and μ instead of k, $\lambda^{(i)}$ and λ) shows that we have $g^{\mu}_{(1^{\lambda_1}), (1^{\lambda_2}), ..., (1^{\lambda_\ell})}(q) = 0$ unless $|(1^{\lambda_1})| + |(1^{\lambda_2})| + \cdots + |(1^{\lambda_\ell})| = |\mu|$ and $(1^{\lambda_1}) + (1^{\lambda_2}) + \cdots + (1^{\lambda_\ell}) \triangleright \mu$. Since $|(1^{\lambda_1})| + |(1^{\lambda_2})| + \cdots + |(1^{\lambda_\ell})| = \left| \underbrace{(1^{\lambda_1}) + (1^{\lambda_2}) + \cdots + (1^{\lambda_\ell})}_{\substack{= \lambda^t \\ (\text{by (13.124.10)})}} \right| = |\lambda^t| = |\lambda| = n$ and $(1^{\lambda_1}) + (1^{\lambda_2}) + \cdots + (1^{\lambda_\ell}) = \lambda^t$ (by (13.124.10)), this rewrites as follows: We have $g^{\mu}_{(1^{\lambda_1}), (1^{\lambda_2}), ..., (1^{\lambda_\ell})}(q) = 0$ unless $n = |\mu|$ and $\lambda^t \triangleright \mu$. In other words, we have $g^{\mu}_{(1^{\lambda_1}), (1^{\lambda_2}), ..., (1^{\lambda_\ell})}(q) = 0$ unless $\mu \in \operatorname{Par}_n$ and $\lambda^t \triangleright \mu$, qed.

summation “$\sum_{\mu\in\operatorname{Par}_n;\ \lambda^t\triangleright\mu}$” without changing the value of the sum (since all addends that we lose are 0). Thus, (13.124.9) rewrites as

$$\varphi\left(e_\lambda\right)=\left(\prod_{i=1}^{\ell} q^{\binom{\lambda_i}{2}}\right)\sum_{\mu\in\operatorname{Par}_n;\ \lambda^t\triangleright\mu} g^{\mu}_{\left(1^{\lambda_1}\right),\left(1^{\lambda_2}\right),\ldots,\left(1^{\lambda_\ell}\right)}\left(q\right)\underline{1}_{J_\mu}$$
$$=\sum_{\mu\in\operatorname{Par}_n;\ \lambda^t\triangleright\mu}\left(\prod_{i=1}^{\ell} q^{\binom{\lambda_i}{2}}\right) g^{\mu}_{\left(1^{\lambda_1}\right),\left(1^{\lambda_2}\right),\ldots,\left(1^{\lambda_\ell}\right)}\left(q\right)\underline{1}_{J_\mu}.$$

Setting $\alpha_{\lambda,\mu}=\left(\prod_{i=1}^{\ell} q^{\binom{\lambda_i}{2}}\right) g^{\mu}_{\left(1^{\lambda_1}\right),\left(1^{\lambda_2}\right),\ldots,\left(1^{\lambda_\ell}\right)}\left(q\right)$, we can rewrite this as $\varphi\left(e_\lambda\right)=\sum_{\mu\in\operatorname{Par}_n;\ \lambda^t\triangleright\mu}\alpha_{\lambda,\mu}\underline{1}_{J_\mu}$. Thus, we will be done solving Exercise 4.9.6(d) as soon as we can prove the inequality

$$\left(\prod_{i=1}^{\ell} q^{\binom{\lambda_i}{2}}\right) g^{\lambda^t}_{\left(1^{\lambda_1}\right),\left(1^{\lambda_2}\right),\ldots,\left(1^{\lambda_\ell}\right)}\left(q\right)\neq 0.$$

But the latter inequality follows from $q\neq 0$ and (13.124.8). Thus, Exercise 4.9.6(d) is solved.

(e) The map $\varphi:\Lambda_{\mathbb{C}}\to\mathcal{H}$ is graded, and thus, in order to prove that φ is injective, it is enough to show that the restriction $\varphi\mid_{\left(\Lambda_{\mathbb{C}}\right)_n}$ of φ to $\left(\Lambda_{\mathbb{C}}\right)_n$ is injective for every $n\in\mathbb{N}$. So let us fix $n\in\mathbb{N}$.

We know that $\left(e_\lambda\right)_{\lambda\in\operatorname{Par}_n}$ is a basis of the $\mathbb{C}$-vector space $\left(\Lambda_{\mathbb{C}}\right)_n$. [903] Hence, $\left(e_{\lambda^t}\right)_{\lambda\in\operatorname{Par}_n}$ also is a basis of the $\mathbb{C}$-vector space $\left(\Lambda_{\mathbb{C}}\right)_n$. Every $\lambda\in\operatorname{Par}_n$ satisfies

$$\varphi\left(e_{\lambda^t}\right)=\sum_{\mu\in\operatorname{Par}_n;\ \left(\lambda^t\right)^t\triangleright\mu}\alpha_{\lambda^t,\mu}\underline{1}_{J_\mu}$$

for some coefficients $\alpha_{\lambda^t,\mu}\in\mathbb{C}$ satisfying $\alpha_{\lambda^t,\left(\lambda^t\right)^t}\neq 0$ (according to Exercise 4.9.6(d)). In other words, every $\lambda\in\operatorname{Par}_n$ satisfies

$$\varphi\left(e_{\lambda^t}\right)=\sum_{\mu\in\operatorname{Par}_n;\ \lambda\triangleright\mu}\alpha_{\lambda^t,\mu}\underline{1}_{J_\mu}\qquad(13.124.12)$$

for some coefficients $\alpha_{\lambda^t,\mu}\in\mathbb{C}$ satisfying $\alpha_{\lambda^t,\lambda}\neq 0$ (since $\left(\lambda^t\right)^t=\lambda$).

Now, regard the set Par_n as a poset with the smaller-or-equal relation $\triangleright$.

The $\mathbb{C}$-vector space basis $\left(e_{\lambda^t}\right)_{\lambda\in\operatorname{Par}_n}$ of $\left(\Lambda_{\mathbb{C}}\right)_n$ and the $\mathbb{C}$-vector space basis $\left(\underline{1}_{J_\lambda}\right)_{\lambda\in\operatorname{Par}_n}$ of $\mathcal{H}_n$ are both indexed by the poset Par_n, and the $\operatorname{Par}_n\times\operatorname{Par}_n$-matrix that represents the map $\varphi\mid_{\left(\Lambda_{\mathbb{C}}\right)_n}$ with respect to these bases[904] is triangular[905] (by (13.124.12)). Furthermore, the diagonal entries of this triangular matrix are nonzero (due to $\alpha_{\lambda^t,\lambda}\neq 0$), and therefore invertible (in $\mathbb{C}$). Hence, this matrix is invertibly triangular, and thus invertible[906]. Therefore, the map $\varphi\mid_{\left(\Lambda_{\mathbb{C}}\right)_n}$ (which is represented by this matrix) is invertible (as a linear map $\left(\Lambda_{\mathbb{C}}\right)_n\to\mathcal{H}_n$) and thus injective. This completes the solution to Exercise 4.9.6(e).

13.125. **Solution to Exercise 5.2.13.** *Solution to Exercise 5.2.13.*

Alternative proof of Theorem 5.2.11. Let P be a labelled poset.

First of all, let f be any map $P\to\{1,2,3,\ldots\}$. We define a binary relation $\prec_f$ on the set P by letting $i\prec_f j$ hold if and only if

$$\left(f\left(i\right)<f\left(j\right)\ \text{ or }\ \left(f\left(i\right)=f\left(j\right)\ \text{ and }\ i<_{\mathbb{Z}} j\right)\right).$$

[903] This has been proven in the proof of Proposition 2.2.10. (Alternatively, this can be easily concluded from Proposition 2.2.10.)

[904] i.e., the $\operatorname{Par}_n\times\operatorname{Par}_n$-matrix whose $\left(\mu,\lambda\right)$-th entry is the $\underline{1}_{J_\mu}$-coordinate of $\varphi\left(e_{\lambda^t}\right)$

[905] See Definition 11.1.7 for the notation we are using here.

[906] by Proposition 11.1.10(d)

It is straightforward to see that this binary relation $\prec_f$ is the smaller relation of a total order on P. Let us define $\mathbf{w}(f)$ to be the set P endowed with this total order. Thus, $\mathbf{w}(f) = P$ as sets, but the smaller relation $<_{\mathbf{w}(f)}$ of the totally ordered set $\mathbf{w}(f)$ is the relation $\prec_f$.

Let us now forget that we fixed f. Thus, for every map $f : P \to \{1, 2, 3, \ldots\}$, we have constructed a binary relation $\prec_f$ on the set P and a totally ordered poset $\mathbf{w}(f)$. It is easy to see that, for every $f \in \mathcal{A}(P)$, we have

$$\mathbf{w}(f) \in \mathcal{L}(P) \tag{13.125.1}$$

[907].

Now, fix $w \in \mathcal{L}(P)$. Thus, w is a linear extension of P. That is, w is a totally ordered set with ground set P, and extends the poset P.

Let us first show that

$$\{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\} \subset \mathcal{A}(w). \tag{13.125.2}$$

[*Proof of (13.125.2):* Let $f \in \{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\}$. Hence, f is an element of $\mathcal{A}(P)$ and satisfies $\mathbf{w}(f) = w$. Therefore, $w = \mathbf{w}(f) = P$ as sets.

Our next goal is to prove $f \in \mathcal{A}(w)$. In other words, we want to prove that f is a w-partition.

Indeed, we claim that

$$(\text{if } i \in w \text{ and } j \in w \text{ satisfy } i <_w j \text{ and } i <_{\mathbb{Z}} j, \text{ then } f(i) \leq f(j)) \tag{13.125.3}$$

and

$$(\text{if } i \in w \text{ and } j \in w \text{ satisfy } i <_w j \text{ and } i >_{\mathbb{Z}} j, \text{ then } f(i) < f(j)). \tag{13.125.4}$$

Let us prove (13.125.3) first. So let i and j be two elements of w satisfying $i <_w j$ and $i <_{\mathbb{Z}} j$. We have $i <_w j$, thus $i <_{\mathbf{w}(f)} j$ (since $w = \mathbf{w}(f)$), and thus $i \prec_f j$ (since the relation $<_{\mathbf{w}(f)}$ is the relation $\prec_f$). By the definition of $\prec_f$, this means that we have $(f(i) < f(j)$ or $(f(i) = f(j)$ and $i <_{\mathbb{Z}} j))$. From this, we immediately obtain $f(i) \leq f(j)$. Thus, (13.125.3) is proven.

The proof of (13.125.4) is similar to the proof that we just gave for (13.125.3), but with a minor twist: In order to derive $f(i) < f(j)$ from $(f(i) < f(j)$ or $(f(i) = f(j)$ and $i <_{\mathbb{Z}} j))$, we need to recall the assumption $i >_{\mathbb{Z}} j$ (which rules out the possibility $(f(i) = f(j)$ and $i <_{\mathbb{Z}} j)$).

Thus, both (13.125.3) and (13.125.4) are proven. In other words, f is a w-partition. In yet other words, $f \in \mathcal{A}(w)$.

Let us now forget that we fixed f. We thus have proven that every $f \in \{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\}$ satisfies $f \in \mathcal{A}(w)$. In other words, (13.125.2) is proven.]

Let us next show that

$$\mathcal{A}(w) \subset \{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\}. \tag{13.125.5}$$

[*Proof of (13.125.5):* Let $f \in \mathcal{A}(w)$. Thus, f is a w-partition. We shall next prove that $f \in \{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\}$.

Indeed, let us first make a general and trivial observation: If Q and R are two labelled posets such that $Q = R$ as sets, and if every two elements i and j of Q satisfying $i <_Q j$ satisfy $i <_R j$ (that is, the poset R is

[907] *Proof of (13.125.1):* Let $f \in \mathcal{A}(P)$. We need to show that $\mathbf{w}(f) \in \mathcal{L}(P)$. In other words, we need to show that $\mathbf{w}(f)$ is a linear extension of P. In order to show this, it clearly suffices to prove that every two elements i and j of P satisfying $i <_P j$ satisfy $i <_{\mathbf{w}(f)} j$ (because we already know that $\mathbf{w}(f)$ is a totally ordered set). So, let us fix two elements i and j of P satisfying $i <_P j$. We need to prove that $i <_{\mathbf{w}(f)} j$.

We have $i <_P j$ and thus $i \neq j$. Hence, either $i <_{\mathbb{Z}} j$ or $i >_{\mathbb{Z}} j$. In other words, we are in one of the following two Cases:

Case 1: We have $i <_{\mathbb{Z}} j$.

Case 2: We have $i >_{\mathbb{Z}} j$.

Let us first consider Case 1. In this case, $i <_{\mathbb{Z}} j$. But f is a P-partition (since $f \in \mathcal{A}(P)$), and thus, by the definition of a P-partition, we conclude that $f(i) \leq f(j)$ (since $i <_P j$ and $i <_{\mathbb{Z}} j$). In other words, either $f(i) < f(j)$ or $f(i) = f(j)$. Therefore, either $f(i) < f(j)$ or $(f(i) = f(j)$ and $i <_{\mathbb{Z}} j)$ (because we have $i <_{\mathbb{Z}} j$ by assumption). In other words, $i \prec_f j$. This rewrites as $i <_{\mathbf{w}(f)} j$ (since the relation $<_{\mathbf{w}(f)}$ is the relation $\prec_f$). Thus, $i <_{\mathbf{w}(f)} j$ is proven in Case 1.

Let us now consider Case 2. In this case, $i >_{\mathbb{Z}} j$. But f is a P-partition (since $f \in \mathcal{A}(P)$), and thus, by the definition of a P-partition, we conclude that $f(i) < f(j)$ (since $i <_P j$ and $i >_{\mathbb{Z}} j$). Therefore, either $f(i) < f(j)$ or $(f(i) = f(j)$ and $i <_{\mathbb{Z}} j)$. In other words, $i \prec_f j$. This rewrites as $i <_{\mathbf{w}(f)} j$ (since the relation $<_{\mathbf{w}(f)}$ is the relation $\prec_f$). Thus, $i <_{\mathbf{w}(f)} j$ is proven in Case 2.

We have now proven $i <_{\mathbf{w}(f)} j$ in both Cases 1 and 2; thus, $i <_{\mathbf{w}(f)} j$ always holds. This completes the proof of (13.125.1).

an extension of the poset Q), then every R-partition is a Q-partition.[908] Applying this to $Q = P$ and $R = w$, we conclude that every w-partition is a P-partition. Thus, f is a P-partition (since f is a w-partition). In other words, $f \in \mathcal{A}(P)$.

Next, we want to check that $\mathbf{w}(f) = w$.

It is easy to check that every two elements i and j of w satisfying $i <_w j$ satisfy

$$i <_{\mathbf{w}(f)} j \tag{13.125.6}$$

[909]. Now, let us again state a triviality: If Q and R are two totally ordered sets such that $Q = R$ as sets, and if every two elements i and j of Q satisfying $i <_Q j$ satisfy $i <_R j$, then $Q = R$ as totally ordered sets.[910] Applying this to $Q = w$ and $R = \mathbf{w}(f)$, we conclude that $w = \mathbf{w}(f)$ as totally ordered sets (since every two elements i and j of w satisfying $i <_w j$ satisfy $i <_{\mathbf{w}(f)} j$). In other words, $\mathbf{w}(f) = w$.

Now, we know that $f \in \mathcal{A}(P)$ and $\mathbf{w}(f) = w$. In other words, $f \in \{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\}$.

Let us now forget that we fixed f. We thus have shown that $f \in \{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\}$ for every $f \in \mathcal{A}(w)$. This proves (13.125.5).]

Combining (13.125.2) with (13.125.5), we obtain

$$\{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\} = \mathcal{A}(w). \tag{13.125.7}$$

Let us now forget that we fixed w. We thus have proven (13.125.7) for every $w \in \mathcal{L}(P)$.

Now, the definition of $F_P(\mathbf{x})$ yields

$$\begin{aligned} F_P(\mathbf{x}) &= \sum_{f \in \mathcal{A}(P)} \mathbf{x}_f = \underbrace{\sum_{w \in \mathcal{L}(P)} \underbrace{\sum_{\substack{f \in \mathcal{A}(P); \\ \mathbf{w}(f) = w}}}_{\substack{= \sum_{f \in \{g \in \mathcal{A}(P) \mid \mathbf{w}(g) = w\}} \\ = \sum_{f \in \mathcal{A}(w)} \\ \text{(by (13.125.7))}}} \mathbf{x}_f}_{} \\ &\qquad \left(\text{since } \mathbf{w}(f) \in \mathcal{L}(P) \text{ for every } f \in \mathcal{A}(P) \text{ (by (13.125.1))}\right) \\ &= \sum_{w \in \mathcal{L}(P)} \underbrace{\sum_{f \in \mathcal{A}(w)} \mathbf{x}_f}_{\substack{= F_w(\mathbf{x}) \\ \text{(since } F_w(\mathbf{x}) = \sum_{f \in \mathcal{A}(w)} \mathbf{x}_f \\ \text{(by the definition of } F_w(\mathbf{x})\text{))}}} = \sum_{w \in \mathcal{L}(P)} F_w(\mathbf{x}). \end{aligned}$$

This completes our proof of Theorem 5.2.11. □

13.126. **Solution to Exercise 5.3.7.** *Solution to Exercise 5.3.7.* Let us first state a basic fact about totally ordered sets:

Lemma 13.126.1. *Let T be a totally ordered set, and let $<_T$ be the smaller relation of T. Let $(a_1, a_2, \ldots, a_n)$ be a finite list of* ***distinct*** *elements of T. Then, there is a* ***unique*** *permutation $\sigma \in \mathfrak{S}_n$ such that $a_{\sigma(1)} <_T a_{\sigma(2)} <_T \cdots <_T a_{\sigma(n)}$.*

[908] This is clear, because the requirements for an R-partition are at least as strong as the requirements for a Q-partition.

[909] *Proof of (13.125.6):* Let i and j be two elements of w satisfying $i <_w j$. We must prove that $i <_{\mathbf{w}(f)} j$.

We have $i <_w j$ and thus $i \neq j$. Hence, either $i <_{\mathbb{Z}} j$ or $i >_{\mathbb{Z}} j$. In other words, we are in one of the following two Cases:

Case 1: We have $i <_{\mathbb{Z}} j$.

Case 2: We have $i >_{\mathbb{Z}} j$.

Let us consider Case 1 first. In this case, we have $i <_{\mathbb{Z}} j$. Since f is a w-partition, we have $f(i) \leq f(j)$ (because $i <_w j$ and $i <_{\mathbb{Z}} j$). In other words, $(f(i) < f(j)$ or $f(i) = f(j))$. Hence, $(f(i) < f(j)$ or $(f(i) = f(j)$ and $i <_{\mathbb{Z}} j))$ (because we have assumed that $i <_{\mathbb{Z}} j$). Therefore, $i \prec_f j$ (because of the definition of "$i \prec_f j$"). In other words, $i <_{\mathbf{w}(f)} j$ (since the relation $<_{\mathbf{w}(f)}$ is the relation $\prec_f$). Thus, $i <_{\mathbf{w}(f)} j$ is proven in Case 1.

We can similarly prove $i <_{\mathbf{w}(f)} j$ in Case 2 (but now we obtain $f(i) < f(j)$ instead of $f(i) \leq f(j)$).

We have now shown that $i <_{\mathbf{w}(f)} j$ in both Cases 1 and 2. Thus, (13.125.6) is proven.

[910] In other words: If a totally ordered set R is an extension of a totally ordered set Q, then $Q = R$.

Lemma 13.126.1 is well-known (it essentially says that a finite list of distinct elements of a totally ordered set can be sorted into increasing order by a unique permutation). We shall use it to prove Proposition 5.3.2 later.

Next, we state an elementary property of permutations:

Proposition 13.126.2. *Let $n \in \mathbb{N}$. Let φ and ψ be two elements of $\mathfrak{S}_n$. Assume that for every two elements $a \in \{1, 2, \ldots, n\}$ and $b \in \{1, 2, \ldots, n\}$ satisfying $a < b$, we have*

$$(\varphi(a) < \varphi(b) \text{ if and only if } \psi(a) < \psi(b)). \tag{13.126.1}$$

Then, $\varphi = \psi$.

Proof of Proposition 13.126.2. If a and b are two elements of $\{1, 2, \ldots, n\}$ satisfying $a < b$, then we have the logical equivalence

$$(\varphi(a) < \varphi(b)) \iff (\psi(a) < \psi(b)) \tag{13.126.2}$$

(by (13.126.1)). We next will show that this equivalence holds even if we don't require $a < b$:

> *Observation 1:* Let $p \in \{1, 2, \ldots, n\}$ and $q \in \{1, 2, \ldots, n\}$. Then, we have the logical equivalence
> $$(\varphi(p) < \varphi(q)) \iff (\psi(p) < \psi(q)).$$

[*Proof of Observation 1:* Let us first prove the logical implication

$$(\varphi(p) < \varphi(q)) \implies (\psi(p) < \psi(q)). \tag{13.126.3}$$

[*Proof of (13.126.3):* Assume that $\varphi(p) < \varphi(q)$. We want to show that $\psi(p) < \psi(q)$.

If $p < q$, then (13.126.2) (applied to $a = p$ and $b = q$) yields the equivalence $(\varphi(p) < \varphi(q)) \iff (\psi(p) < \psi(q))$, and thus $\psi(p) < \psi(q)$ follows (since $\varphi(p) < \varphi(q)$). Hence, for the rest of the proof of $\psi(p) < \psi(q)$, we WLOG assume that we don't have $p < q$. Hence, we have $p \geq q$.

From $\varphi(p) < \varphi(q)$, we also obtain $\varphi(p) \neq \varphi(q)$, so that $p \neq q$. Combining this with $p \geq q$, we obtain $p > q$. Hence, $q < p$. Thus, (13.126.2) (applied to $a = q$ and $b = p$) yields the logical equivalence $(\varphi(q) < \varphi(p)) \iff (\psi(q) < \psi(p))$. Since we don't have $\varphi(q) < \varphi(p)$ (because $\varphi(p) < \varphi(q)$), we thus conclude that we don't have $\psi(q) < \psi(p)$. Therefore, we have $\psi(p) \leq \psi(q)$. But the map ψ is injective (since $\psi \in \mathfrak{S}_n$); therefore, from $p \neq q$, we obtain $\psi(p) \neq \psi(q)$. Combining this with $\psi(p) \leq \psi(q)$, we obtain $\psi(p) < \psi(q)$. This completes the proof of (13.126.3).]

So we have proven (13.126.3). The same argument (but with the roles of φ and ψ interchanged) yields the logical implication

$$(\psi(p) < \psi(q)) \implies (\varphi(p) < \varphi(q)).$$

Combining this with (13.126.3), we obtain the equivalence $(\varphi(p) < \varphi(q)) \iff (\psi(p) < \psi(q))$. This proves Observation 1.]

Now, let $q \in \{1, 2, \ldots, n\}$. Then, the map φ is a bijection $\{1, 2, \ldots, n\} \to \{1, 2, \ldots, n\}$ (since $\varphi \in \mathfrak{S}_n$). Thus, we can substitute i for $\varphi(p)$ in the sum $\sum_{\substack{p \in \{1,2,\ldots,n\}; \\ \varphi(p) < \varphi(q)}} 1$. We thus obtain

$$\sum_{\substack{p \in \{1,2,\ldots,n\}; \\ \varphi(p) < \varphi(q)}} 1 = \sum_{\substack{i \in \{1,2,\ldots,n\}; \\ i < \varphi(q)}} 1 = \sum_{i \in \{1,2,\ldots,\varphi(q)-1\}} 1 = (\varphi(q) - 1) \cdot 1 = \varphi(q) - 1. \tag{13.126.4}$$

The same argument (applied to ψ instead of φ) yields

$$\sum_{\substack{p \in \{1,2,\ldots,n\}; \\ \psi(p) < \psi(q)}} 1 = \psi(q) - 1.$$

However, Observation 1 shows that the sums $\sum_{\substack{p \in \{1,2,\ldots,n\}; \\ \varphi(p) < \varphi(q)}} 1$ and $\sum_{\substack{p \in \{1,2,\ldots,n\}; \\ \psi(p) < \psi(q)}} 1$ range over the same values of p. Thus,

$$\sum_{\substack{p \in \{1,2,\ldots,n\}; \\ \varphi(p) < \varphi(q)}} 1 = \sum_{\substack{p \in \{1,2,\ldots,n\}; \\ \psi(p) < \psi(q)}} 1 = \psi(q) - 1.$$

Comparing this with (13.126.4), we obtain $\varphi(q) - 1 = \psi(q) - 1$. Hence, $\varphi(q) = \psi(q)$.

Now, forget that we fixed q. We thus have shown that $\varphi(q) = \psi(q)$ for each $q \in \{1, 2, \ldots, n\}$. In other words, $\varphi = \psi$. This proves Proposition 13.126.2. □

For later use (in a different solution further below), let us derive another proposition from Proposition 13.126.2. It relies on the following notation:

Definition 13.126.3. Let $n \in \mathbb{N}$. Let $\varphi \in \mathfrak{S}_n$. Define the *inversion set* $\operatorname{Inv}\varphi$ of φ to be the set $\left\{(i,j) \in \{1,2,\ldots,n\}^2 \mid i < j;\ \varphi(i) > \varphi(j)\right\}$.

(Note that this notation is not completely standard. Some authors, instead, define $\operatorname{Inv}\varphi$ to be $\left\{(\varphi(i), \varphi(j)) \mid (i,j) \in \{1,2,\ldots,n\}^2;\ i < j;\ \varphi(i) > \varphi(j)\right\}$. This is a different set, although of the same size.)

Proposition 13.126.4. *Let $n \in \mathbb{N}$. Let φ and ψ be two elements of $\mathfrak{S}_n$ satisfying $\operatorname{Inv}\varphi = \operatorname{Inv}\psi$. Then, $\varphi = \psi$.*

(Proposition 13.126.4 can be restated as follows: If $n \in \mathbb{N}$, then a permutation in $\mathfrak{S}_n$ is uniquely determined by its inversion set.)

Proposition 13.126.4 is a known fact in elementary combinatorics; let us quickly derive it from Proposition 13.126.2:

Proof of Proposition 13.126.4. Let $a \in \{1,2,\ldots,n\}$ and $b \in \{1,2,\ldots,n\}$ be such that $a < b$. We shall prove that $\varphi(a) < \varphi(b)$ if and only if $\psi(a) < \psi(b)$.

The pair (a,b) is an element of $\{1,2,\ldots,n\}^2$ satisfying $a < b$. Thus, (a,b) belongs to $\operatorname{Inv}\varphi$ if and only if it satisfies $\varphi(a) > \varphi(b)$ (by the definition of $\operatorname{Inv}\varphi$). In other words, we have the following logical equivalence:

$$((a,b) \in \operatorname{Inv}\varphi) \iff (\varphi(a) > \varphi(b)). \tag{13.126.5}$$

But the map φ is injective (since $\varphi \in \mathfrak{S}_n$). Thus, from $a \neq b$ (which follows from $a < b$), we obtain $\varphi(a) \neq \varphi(b)$. Hence, $\varphi(a) < \varphi(b)$ holds if and only if $\varphi(a) \leq \varphi(b)$. Hence, we have the following chain of equivalences:

$$(\varphi(a) < \varphi(b)) \iff (\varphi(a) \leq \varphi(b)) \iff \left(\text{not } \underbrace{(\varphi(a) > \varphi(b))}_{\substack{\iff (a,b)\in\operatorname{Inv}\varphi \\ \text{(by (13.126.5))}}}\right)$$
$$\iff (\text{not } ((a,b) \in \operatorname{Inv}\varphi)). \tag{13.126.6}$$

The same argument (applied to ψ instead of φ) yields the equivalence

$$(\psi(a) < \psi(b)) \iff (\text{not } ((a,b) \in \operatorname{Inv}\psi)). \tag{13.126.7}$$

Now, due to (13.126.6), we have the following chain of equivalences:

$$(\varphi(a) < \varphi(b)) \iff (\text{not } ((a,b) \in \operatorname{Inv}\varphi)) \iff (\text{not } ((a,b) \in \operatorname{Inv}\psi)) \qquad (\text{since } \operatorname{Inv}\varphi = \operatorname{Inv}\psi)$$
$$\iff (\psi(a) < \psi(b))$$

(by (13.126.7)). In other words, we have $\varphi(a) < \varphi(b)$ if and only if $\psi(a) < \psi(b)$.

Now, forget that we fixed a and b. We thus have shown that for every two elements $a \in \{1,2,\ldots,n\}$ and $b \in \{1,2,\ldots,n\}$ satisfying $a < b$, we have

$$(\varphi(a) < \varphi(b) \text{ if and only if } \psi(a) < \psi(b)).$$

Thus, Proposition 13.126.2 yields $\varphi = \psi$. This proves Proposition 13.126.4. □

We are now ready to prove Proposition 5.3.2:

Proof of Proposition 5.3.2. Define a binary relation $\prec$ on the set $\{1, 2, \ldots, n\}$ by letting $i \prec j$ hold if and only if

$$\left(w_i < w_j \text{ or } \left(w_i = w_j \text{ and } i <_{\mathbb{Z}} j\right)\right).$$

It is easy to see that this relation $\prec$ is the smaller relation of a total order. Let T denote the set $\{1, 2, \ldots, n\}$ endowed with this total order. Thus, $T = \{1, 2, \ldots, n\}$ as sets, but the smaller relation $<_T$ of the poset T is the relation $\prec$.

Clearly, $(1, 2, \ldots, n)$ is a finite list of distinct elements of this totally ordered set T. Hence, Lemma 13.126.1 (applied to $a_i = i$) yields that there is a **unique** permutation $\sigma \in \mathfrak{S}_n$ such that $\sigma(1) <_T \sigma(2) <_T \cdots <_T \sigma(n)$. Consider this σ, and denote it by γ. Thus, γ is a permutation in $\mathfrak{S}_n$ and satisfies $\gamma(1) <_T \gamma(2) <_T \cdots <_T \gamma(n)$. Hence, $\gamma^{-1} \in \mathfrak{S}_n$ as well.

We have $\gamma(1) <_T \gamma(2) <_T \cdots <_T \gamma(n)$. In other words, if i and j are two elements of $\{1, 2, \ldots, n\}$ satisfying $i < j$, then

$$\gamma(i) <_T \gamma(j). \tag{13.126.8}$$

Thus, for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have

$$\left(\gamma^{-1}(a) < \gamma^{-1}(b) \text{ if and only if } w_a \leq w_b\right). \tag{13.126.9}$$

[*Proof of (13.126.9):* Let a and b be two elements of $\{1, 2, \ldots, n\}$ satisfying $a < b$. Set $i = \gamma^{-1}(a)$ and $j = \gamma^{-1}(b)$. Thus, i and j are two elements of $\{1, 2, \ldots, n\}$ (since $\gamma^{-1} \in \mathfrak{S}_n$). Also, from $i = \gamma^{-1}(a)$, we obtain $\gamma(i) = a$. From $j = \gamma^{-1}(b)$, we obtain $\gamma(j) = b$.

We are in one of the following two cases:

Case 1: We have $i < j$.

Case 2: We have $i \geq j$.

Let us first consider Case 1. In this case, we have $i < j$. This rewrites as $\gamma^{-1}(a) < \gamma^{-1}(b)$ (since $i = \gamma^{-1}(a)$ and $j = \gamma^{-1}(b)$). On the other hand, from $i < j$, we obtain $\gamma(i) <_T \gamma(j)$ (by (13.126.8)). This rewrites as $a <_T b$ (since $\gamma(i) = a$ and $\gamma(j) = b$). This rewrites as $a \prec b$ (since the relation $<_T$ is the relation $\prec$). In other words, $\left(f(a) < f(b) \text{ or } \left(f(a) = f(b) \text{ and } a <_{\mathbb{Z}} b\right)\right)$ (by the definition of the relation $\prec$). Thus, $f(a) \leq f(b)$. But the definition of f yields $f(a) = w_a$ and $f(b) = w_b$. Thus, $w_a = f(a) \leq f(b) = w_b$. Now, we have shown that both statements $\left(\gamma^{-1}(a) < \gamma^{-1}(b)\right)$ and $(w_a \leq w_b)$ are true. Hence, we have $\left(\gamma^{-1}(a) < \gamma^{-1}(b) \text{ if and only if } w_a \leq w_b\right)$. This proves (13.126.9) in Case 1.

Let us now consider Case 2. In this case, we have $i \geq j$. This rewrites as $\gamma^{-1}(a) \geq \gamma^{-1}(b)$ (since $i = \gamma^{-1}(a)$ and $j = \gamma^{-1}(b)$). Hence, the statement $\left(\gamma^{-1}(a) < \gamma^{-1}(b)\right)$ is false.

We have $a < b$. Thus, we cannot have $b < a$. In other words, we cannot have $b <_{\mathbb{Z}} a$. Thus, we cannot have $\left(f(b) = f(a) \text{ and } b <_{\mathbb{Z}} a\right)$.

If we had $i = j$, then we would have $a = \gamma\left(\underbrace{i}_{=j}\right) = \gamma(j) = b$, which would contradict $a < b$. Hence, we cannot have $i = j$. Thus, we have $i \neq j$. Combining this with $i \geq j$, we obtain $i > j$. Therefore, $j < i$. Therefore, (13.126.8) (applied to j and i instead of i and j) yields $\gamma(j) <_T \gamma(i)$. This rewrites as $b <_T a$ (since $\gamma(i) = a$ and $\gamma(j) = b$). This rewrites as $b \prec a$ (since the relation $<_T$ is the relation $\prec$). In other words, $\left(f(b) < f(a) \text{ or } \left(f(b) = f(a) \text{ and } b <_{\mathbb{Z}} a\right)\right)$ (by the definition of the relation $\prec$). Hence, we must have $f(b) < f(a)$ (since we cannot have $\left(f(b) = f(a) \text{ and } b <_{\mathbb{Z}} a\right)$). But the definition of f yields $f(a) = w_a$ and $f(b) = w_b$. Thus, $w_b = f(b) < f(a) = w_a$. Hence, the statement $(w_a \leq w_b)$ is false. Now, we have shown that both statements $\left(\gamma^{-1}(a) < \gamma^{-1}(b)\right)$ and $(w_a \leq w_b)$ are false. Hence, we have $\left(\gamma^{-1}(a) < \gamma^{-1}(b) \text{ if and only if } w_a \leq w_b\right)$. This proves (13.126.9) in Case 2.

We have now proven (13.126.9) in each of the two Cases 1 and 2. Hence, (13.126.9) is always proven.]

So we know that γ^{-1} is a permutation in $\mathfrak{S}_n$, and that for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have $\left(\gamma^{-1}(a) < \gamma^{-1}(b) \text{ if and only if } w_a \leq w_b\right)$ (by (13.126.9)). Thus, there exists **at least one** permutation $\sigma \in \mathfrak{S}_n$ such that for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have $\left(\sigma(a) < \sigma(b) \text{ if and only if } w_a \leq w_b\right)$ (namely, $\sigma = \gamma^{-1}$).

It remains to prove that there exists **at most one** such permutation σ. In other words, it remains to prove that any two such permutations σ are equal. In other words, it remains to prove the following claim:

> *Claim 1:* Let φ and ψ be two permutations $\sigma \in \mathfrak{S}_n$ such that for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have $(\sigma(a) < \sigma(b)$ if and only if $w_a \leq w_b)$. Then, $\varphi = \psi$.

[*Proof of Claim 1:* We know that φ is a permutation $\sigma \in \mathfrak{S}_n$ such that for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have $(\sigma(a) < \sigma(b)$ if and only if $w_a \leq w_b)$. In other words, φ is a permutation in $\mathfrak{S}_n$, and has the property that for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have

$$(\varphi(a) < \varphi(b) \text{ if and only if } w_a \leq w_b). \tag{13.126.10}$$

Now, let a and b be two elements of $\{1, 2, \ldots, n\}$ satisfying $a < b$. Then, from (13.126.10), we obtain the logical equivalence $(\varphi(a) < \varphi(b)) \iff (w_a \leq w_b)$. The same argument (applied to ψ instead of φ) yields the logical equivalence $(\psi(a) < \psi(b)) \iff (w_a \leq w_b)$. Hence, we have the following chain of logical equivalences:

$$(\varphi(a) < \varphi(b)) \iff (w_a \leq w_b) \iff (\psi(a) < \psi(b))$$

(because of the equivalence $(\psi(a) < \psi(b)) \iff (w_a \leq w_b)$). In other words, we have

$$(\varphi(a) < \varphi(b) \text{ if and only if } \psi(a) < \psi(b)).$$

Now, forget that we fixed a and b. We thus have proven that for every two elements $a \in \{1, 2, \ldots, n\}$ and $b \in \{1, 2, \ldots, n\}$ satisfying $a < b$, we have

$$(\varphi(a) < \varphi(b) \text{ if and only if } \psi(a) < \psi(b)).$$

Thus, Proposition 13.126.2 yields that $\varphi = \psi$. This proves Claim 1.]

Hence, Proposition 5.3.2 is proven. □

Next, we shall show a lemma that will be crucial in our proof of Lemma 5.3.6:

Lemma 13.126.5. *Let $n \in \mathbb{N}$. Let $\tau \in \mathfrak{S}_n$. Let P be the labelled poset whose underlying set is $\{1, 2, \ldots, n\}$ and which (as a poset) is the total order $(\tau(1) < \tau(2) < \cdots < \tau(n))$ (that is, the order $<_P$ is given by $\tau(1) <_P \tau(2) <_P \cdots <_P \tau(n)$).*

Let $\mathfrak{A}$ denote the totally ordered set $\{1 < 2 < 3 < \cdots\}$ of positive integers. Let $f : P \to \mathfrak{A}$ be any map. Then, we have the following logical equivalence:

$$(f \in \mathcal{A}(P)) \iff \left(\operatorname{std}(f(1), f(2), \ldots, f(n)) = \tau^{-1}\right)$$

(where we treat $(f(1), f(2), \ldots, f(n))$ as a word in $\mathfrak{A}^n$).

Proof of Lemma 13.126.5. We have $P = \{1, 2, \ldots, n\}$ as sets. Also, the definition of the order $<_P$ yields

$$\tau(1) <_P \tau(2) <_P \cdots <_P \tau(n).$$

Hence, for any two elements i and j of $\{1, 2, \ldots, n\}$, we have

$$(\tau(i) <_P \tau(j) \text{ if and only if } i < j) \tag{13.126.11}$$

(where the "$<$" sign in "$i < j$" refers to the usual smaller relation $<_{\mathbb{Z}}$ of the totally ordered set $\mathbb{Z}$).

The map f is a map from P to $\mathfrak{A}$. In other words, the map f is a map from P to $\{1, 2, 3, \ldots\}$ (since $\mathfrak{A} = \{1, 2, 3, \ldots\}$).

Also, $(f(1), f(2), \ldots, f(n))$ is a word in $\mathfrak{A}^n$. Denote this word by w. Thus,

$$w = (f(1), f(2), \ldots, f(n)) \in \mathfrak{A}^n.$$

For each $i \in \{1, 2, \ldots, n\}$, the i-th letter of the word w has been denoted by w_i. Thus, $w = (w_1, w_2, \ldots, w_n)$, so that $(w_1, w_2, \ldots, w_n) = w = (f(1), f(2), \ldots, f(n))$. In other words,

$$w_i = f(i) \qquad \text{for each } i \in \{1, 2, \ldots, n\}. \tag{13.126.12}$$

The definition of the standardization $\operatorname{std} w$ shows that $\operatorname{std} w$ is the unique permutation $\sigma \in \mathfrak{S}_n$ such that for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have $(\sigma(a) < \sigma(b)$ if and only if $w_a \leq w_b)$. In particular, $\operatorname{std} w$ is such a permutation. In other words, $\operatorname{std} w$ is a permutation in $\mathfrak{S}_n$ and has the property that for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have

$$((\operatorname{std} w)(a) < (\operatorname{std} w)(b) \text{ if and only if } w_a \leq w_b). \tag{13.126.13}$$

Hence, for every two elements a and b of $\{1, 2, \ldots, n\}$ satisfying $a < b$, we have

$$\left((\operatorname{std} w)(a) < (\operatorname{std} w)(b) \text{ if and only if } f(a) \leq f(b)\right). \tag{13.126.14}$$

(Indeed, this just a restatement of (13.126.13), since (13.126.12) yields $w_a = f(a)$ and $w_b = f(b)$.)

We shall next prove the following two claims:

Claim 1: If $f \in \mathcal{A}(P)$, then $\operatorname{std} w = \tau^{-1}$.

Claim 2: If $\operatorname{std} w = \tau^{-1}$, then $f \in \mathcal{A}(P)$.

[*Proof of Claim 1:* Assume that $f \in \mathcal{A}(P)$. Thus, f is a P-partition (since $\mathcal{A}(P)$ is the set of all P-partitions). In other words, f is a map $P \to \{1, 2, 3, \ldots\}$ with the properties

$$(\text{if } i \in P \text{ and } j \in P \text{ satisfy } i <_P j \text{ and } i <_{\mathbb{Z}} j, \text{ then } f(i) \leq f(j)) \tag{13.126.15}$$

and

$$(\text{if } i \in P \text{ and } j \in P \text{ satisfy } i <_P j \text{ and } i >_{\mathbb{Z}} j, \text{ then } f(i) < f(j)) \tag{13.126.16}$$

(because this is how a P-partition is defined).

For every two elements $a \in \{1, 2, \ldots, n\}$ and $b \in \{1, 2, \ldots, n\}$ satisfying $a < b$, we have

$$\left((\operatorname{std} w)(a) < (\operatorname{std} w)(b) \text{ if and only if } \tau^{-1}(a) < \tau^{-1}(b)\right) \tag{13.126.17}$$

[911]. Hence, Proposition 13.126.2 (applied to $\varphi = \operatorname{std} w$ and $\psi = \tau^{-1}$) yields $\operatorname{std} w = \tau^{-1}$. Thus, Claim 1 is proven.]

[*Proof of Claim 2:* Assume that $\operatorname{std} w = \tau^{-1}$. The map $f : P \to \{1, 2, 3, \ldots\}$ has the following properties:

$$(\text{if } i \in P \text{ and } j \in P \text{ satisfy } i <_P j \text{ and } i <_{\mathbb{Z}} j, \text{ then } f(i) \leq f(j)) \tag{13.126.18}$$

[912] and

$$(\text{if } i \in P \text{ and } j \in P \text{ satisfy } i <_P j \text{ and } i >_{\mathbb{Z}} j, \text{ then } f(i) < f(j)) \tag{13.126.19}$$

[911] *Proof of (13.126.17):* Let $a \in \{1, 2, \ldots, n\}$ and $b \in \{1, 2, \ldots, n\}$ be such that $a < b$. We must prove (13.126.17).

We have $a \in \{1, 2, \ldots, n\} = P$ and $b \in \{1, 2, \ldots, n\} = P$.

Note that $a < b$. In other words, $a <_{\mathbb{Z}} b$. In other words, $b >_{\mathbb{Z}} a$.

Let $i = \tau^{-1}(a)$ and $j = \tau^{-1}(b)$. Thus, i and j belong to $\{1, 2, \ldots, n\}$. From $i = \tau^{-1}(a)$, we obtain $a = \tau(i)$. From $j = \tau^{-1}(b)$, we obtain $b = \tau(j)$. If we had $i = j$, then we would have $a = \tau\left(\underbrace{i}_{=j}\right) = \tau(j) = b$, which would contradict $a < b$. Thus, $i \neq j$. Hence, we are in one of the following two cases:

Case 1: We have $i < j$.

Case 2: We have $i > j$.

Let us first consider Case 1. In this case, we have $i < j$. Hence, (13.126.11) shows that $\tau(i) <_P \tau(j)$. In view of $\tau(i) = a$ and $\tau(j) = b$, this rewrites as $a <_P b$. Also, $a <_{\mathbb{Z}} b$. Hence, (13.126.15) (applied to a and b instead of i and j) yields $f(a) \leq f(b)$. Because of (13.126.14), this shows that $(\operatorname{std} w)(a) < (\operatorname{std} w)(b)$. Also, $\tau^{-1}(a) = i < j = \tau^{-1}(b)$. Thus, both statements $((\operatorname{std} w)(a) < (\operatorname{std} w)(b))$ and $\left(\tau^{-1}(a) < \tau^{-1}(b)\right)$ are true. Hence, we have $\left((\operatorname{std} w)(a) < (\operatorname{std} w)(b) \text{ if and only if } \tau^{-1}(a) < \tau^{-1}(b)\right)$. Thus, (13.126.17) is proven in Case 1.

Let us now consider Case 2. In this case, we have $i > j$. Hence, $j < i$. But (13.126.11) (applied to j and i instead of i and j) shows that $\tau(j) <_P \tau(i)$ if and only if $j < i$. Hence, we have $\tau(j) <_P \tau(i)$ (since we have $j < i$). In view of $\tau(i) = a$ and $\tau(j) = b$, this rewrites as $b <_P a$. Also, $b >_{\mathbb{Z}} a$. Hence, (13.126.16) (applied to b and a instead of i and j) yields $f(b) < f(a)$. In other words, we don't have $f(a) \leq f(b)$. Because of (13.126.14), this shows that we don't have $(\operatorname{std} w)(a) < (\operatorname{std} w)(b)$. Also, $\tau^{-1}(a) = i > j = \tau^{-1}(b)$. Hence, we don't have $\tau^{-1}(a) < \tau^{-1}(b)$. Thus, both statements $((\operatorname{std} w)(a) < (\operatorname{std} w)(b))$ and $\left(\tau^{-1}(a) < \tau^{-1}(b)\right)$ are false. Hence, we have $\left((\operatorname{std} w)(a) < (\operatorname{std} w)(b) \text{ if and only if } \tau^{-1}(a) < \tau^{-1}(b)\right)$. Thus, (13.126.17) is proven in Case 2.

We have now proven (13.126.17) in both Cases 1 and 2. Thus, (13.126.17) always holds.

[912] *Proof of (13.126.18):* Let $i \in P$ and $j \in P$ be such that $i <_P j$ and $i <_{\mathbb{Z}} j$. We must prove that $f(i) \leq f(j)$.

Let $a = \tau^{-1}(i)$ and $b = \tau^{-1}(j)$. Thus, $a = \tau^{-1}(i) \in \{1, 2, \ldots, n\} = P$ and $b = \tau^{-1}(j) \in \{1, 2, \ldots, n\} = P$. From $a = \tau^{-1}(i)$, we obtain $\tau(a) = i$. From $b = \tau^{-1}(j)$, we obtain $\tau(b) = j$.

We have $i <_P j$. In view of $i = \tau(a)$ and $j = \tau(b)$, this rewrites as $\tau(a) <_P \tau(b)$.

But (13.126.11) (applied to a and b instead of i and j) shows that $(\tau(a) <_P \tau(b) \text{ if and only if } a < b)$. Hence, we have $a < b$ (since we have $\tau(a) <_P \tau(b)$). Because of $\operatorname{std} w = \tau^{-1}$, we now have $\underbrace{(\operatorname{std} w)}_{=\tau^{-1}}(i) = \tau^{-1}(i) = a < b = \underbrace{\tau^{-1}}_{=\operatorname{std} w}(j) = (\operatorname{std} w)(j)$.

But $i <_{\mathbb{Z}} j$. In other words, $i < j$. Thus, (13.126.14) (applied to i and j instead of a and b) shows that $((\operatorname{std} w)(i) < (\operatorname{std} w)(j) \text{ if and only if } f(i) \leq f(j))$. Thus, $f(i) \leq f(j)$ (since $(\operatorname{std} w)(i) < (\operatorname{std} w)(j)$). This proves (13.126.18).

[913]. Thus, f is a P-partition (because this is how a P-partition is defined). In other words, $f \in \mathcal{A}(P)$ (since $\mathcal{A}(P)$ is the set of all P-partitions). This proves Claim 2.]

Combining Claim 1 with Claim 2, we obtain the logical equivalence $(f \in \mathcal{A}(P)) \iff \left(\operatorname{std} w = \tau^{-1}\right)$. In view of $w = (f(1), f(2), \ldots, f(n))$, this rewrites as

$$(f \in \mathcal{A}(P)) \iff \left(\operatorname{std}(f(1), f(2), \ldots, f(n)) = \tau^{-1}\right).$$

This proves Lemma 13.126.5. □

Next, we will use a trivial consequence of Proposition 5.2.10:

Lemma 13.126.6. *Let $n \in \mathbb{N}$. Let $\sigma \in \mathfrak{S}_n$. Let P be the labelled poset whose underlying set is $\{1, 2, \ldots, n\}$ and which (as a poset) is the total order $(\sigma(1) < \sigma(2) < \cdots < \sigma(n))$ (that is, the order $<_P$ is given by $\sigma(1) <_P \sigma(2) <_P \cdots <_P \sigma(n)$). Then, $F_P(\mathbf{x}) = L_{\gamma(\sigma)}$.*

Proof of Lemma 13.126.6. In Proposition 5.2.10, we have defined $\operatorname{Des} w$ for any labelled poset w that is a total order. Applying this definition to $w = P$, we obtain

$$\operatorname{Des} P = \{i \in \{1, 2, \ldots, n-1\} \mid \sigma(i) >_{\mathbb{Z}} \sigma(i+1)\}$$

(since P is the total order $(\sigma(1) < \sigma(2) < \cdots < \sigma(n))$). Comparing this with

$$\begin{aligned} \operatorname{Des} \sigma &= \{i \in \{1, 2, \ldots, n-1\} \mid \sigma(i) > \sigma(i+1)\} \qquad \text{(by the definition of } \operatorname{Des} \sigma) \\ &= \{i \in \{1, 2, \ldots, n-1\} \mid \sigma(i) >_{\mathbb{Z}} \sigma(i+1)\} \\ &\qquad \text{(since the greater relation } > \text{ of } \mathbb{Z} \text{ is the relation } >_{\mathbb{Z}}), \end{aligned}$$

we obtain $\operatorname{Des} \sigma = \operatorname{Des} P$.

Recall that $\gamma(\sigma)$ is the unique composition α of n satisfying $D(\alpha) = \operatorname{Des} \sigma$ (by the definition of $\gamma(\sigma)$). In other words, $\gamma(\sigma)$ is the unique composition $\alpha \in \operatorname{Comp}_n$ having partial sums $D(\alpha) = \operatorname{Des} \sigma$. In other words, $\gamma(\sigma)$ is the unique composition $\alpha \in \operatorname{Comp}_n$ having partial sums $D(\alpha) = \operatorname{Des} P$ (since $\operatorname{Des} \sigma = \operatorname{Des} P$).

Hence, Proposition 5.2.10 (applied to P, $\sigma(i)$ and $\gamma(\sigma)$ instead of w, w_i and α) yields that the generating function $F_P(\mathbf{x})$ equals the fundamental quasisymmetric function $L_{\gamma(\sigma)}$. Thus, $F_P(\mathbf{x}) = L_{\gamma(\sigma)}$. This proves Lemma 13.126.6. □

Proof of Lemma 5.3.6. We have $\mathfrak{A} = \{1 < 2 < 3 < \cdots\}$; thus, $\mathfrak{A} = \{1, 2, 3, \ldots\}$ as sets.

Let P be the labelled poset whose underlying set is $\{1, 2, \ldots, n\}$ and which (as a poset) is the total order $(\sigma(1) < \sigma(2) < \cdots < \sigma(n))$ (that is, the order $<_P$ is given by $\sigma(1) <_P \sigma(2) <_P \cdots <_P \sigma(n)$). Lemma 13.126.5 (applied to $\tau = \sigma$) yields that if $f : P \to \mathfrak{A}$ is any map, then we have the following logical equivalence:

$$(f \in \mathcal{A}(P)) \iff \left(\operatorname{std}(f(1), f(2), \ldots, f(n)) = \sigma^{-1}\right)$$

(where we treat $(f(1), f(2), \ldots, f(n))$ as a word in $\mathfrak{A}^n$). Hence, we have the following equality of summation signs:

$$\sum_{\substack{f : P \to \mathfrak{A}; \\ f \in \mathcal{A}(P)}} = \sum_{\substack{f : P \to \mathfrak{A}; \\ \operatorname{std}(f(1), f(2), \ldots, f(n)) = \sigma^{-1}}} . \tag{13.126.20}$$

[913] *Proof of (13.126.19):* Let $i \in P$ and $j \in P$ be such that $i <_P j$ and $i >_{\mathbb{Z}} j$. We must prove that $f(i) < f(j)$.

Assume the contrary. Thus, $f(i) \geq f(j)$. In other words, $f(j) \leq f(i)$.

Let $a = \tau^{-1}(i)$ and $b = \tau^{-1}(j)$. Thus, $a = \tau^{-1}(i) \in \{1, 2, \ldots, n\} = P$ and $b = \tau^{-1}(j) \in \{1, 2, \ldots, n\} = P$. From $a = \tau^{-1}(i)$, we obtain $\tau(a) = i$. From $b = \tau^{-1}(j)$, we obtain $\tau(b) = j$.

We have $i <_P j$. In view of $i = \tau(a)$ and $j = \tau(b)$, this rewrites as $\tau(a) <_P \tau(b)$.

But (13.126.11) (applied to a and b instead of i and j) shows that ($\tau(a) <_P \tau(b)$ if and only if $a < b$). Hence, we have $a < b$ (since we have $\tau(a) <_P \tau(b)$).

We have $i >_{\mathbb{Z}} j$. In other words, $i > j$. In other words, $j < i$. Hence, (13.126.14) (applied to j and i instead of a and b) shows that $((\operatorname{std} w)(j) < (\operatorname{std} w)(i)$ if and only if $f(j) \leq f(i))$. Thus, $(\operatorname{std} w)(j) < (\operatorname{std} w)(i)$ (since $f(j) \leq f(i)$). In view of $\operatorname{std} w = \tau^{-1}$, this rewrites as $\tau^{-1}(j) < \tau^{-1}(i)$. Thus, $b = \tau^{-1}(j) < \tau^{-1}(i) = a$. This contradicts $a < b$. This contradiction shows that our assumption was wrong. Hence, $f(i) < f(j)$. This proves (13.126.19).

But every P-partition is a function $P \to \{1,2,3,\ldots\}$. In other words, every P-partition is a function $P \to \mathfrak{A}$ (since $\{1,2,3,\ldots\} = \mathfrak{A}$). In other words, every $f \in \mathcal{A}(P)$ is a function $P \to \mathfrak{A}$ (since $\mathcal{A}(P)$ is the set of all P-partitions). Hence, we have the following equality of summation sums:

$$\sum_{f\in\mathcal{A}(P)} = \sum_{\substack{f:P\to\mathfrak{A};\\ f\in\mathcal{A}(P)}} = \sum_{\substack{f:P\to\mathfrak{A};\\ \operatorname{std}(f(1),f(2),\ldots,f(n))=\sigma^{-1}}}$$

(by (13.126.20)). But Lemma 13.126.6 yields $F_P(\mathbf{x}) = L_{\gamma(\sigma)}$. Hence,

$$\begin{aligned}
L_{\gamma(\sigma)} = F_P(\mathbf{x}) &= \underbrace{\sum_{f\in\mathcal{A}(P)}}_{=\sum_{\substack{f:P\to\mathfrak{A};\\ \operatorname{std}(f(1),f(2),\ldots,f(n))=\sigma^{-1}}}} \underbrace{\mathbf{x}_f}_{\substack{=\prod_{i\in P} x_{f(i)}\\ \text{(by the definition of } \mathbf{x}_f)}} \\
&\qquad \text{(by the definition of } F_P(\mathbf{x})) \\
&= \underbrace{\sum_{\substack{f:P\to\mathfrak{A};\\ \operatorname{std}(f(1),f(2),\ldots,f(n))=\sigma^{-1}}}}_{\substack{=\sum_{\substack{f:\{1,2,\ldots,n\}\to\mathfrak{A};\\ \operatorname{std}(f(1),f(2),\ldots,f(n))=\sigma^{-1}}}\\ \text{(since } P=\{1,2,\ldots,n\})}} \underbrace{\prod_{i\in P} x_{f(i)}}_{\substack{=x_{f(1)}x_{f(2)}\cdots x_{f(n)}\\ \text{(since } P=\{1,2,\ldots,n\})}}
\end{aligned}$$

$$= \sum_{\substack{f:\{1,2,\ldots,n\}\to\mathfrak{A};\\ \operatorname{std}(f(1),f(2),\ldots,f(n))=\sigma^{-1}}} x_{f(1)}x_{f(2)}\cdots x_{f(n)}. \tag{13.126.21}$$

But the map

$$\begin{aligned}
\{\text{functions } \{1,2,\ldots,n\} \to \mathfrak{A}\} &\to \mathfrak{A}^n, \\
f &\mapsto (f(1), f(2), \ldots, f(n))
\end{aligned}$$

is a bijection (indeed, this is just the standard bijection between the functions $\{1,2,\ldots,n\} \to \mathfrak{A}$ and the n-tuples of elements of $\mathfrak{A}$). Hence, we can substitute $(w_1, w_2, \ldots, w_n)$ for $(f(1), f(2), \ldots, f(n))$ in the sum on the right hand side of (13.126.21). We thus obtain

$$\sum_{\substack{f:\{1,2,\ldots,n\}\to\mathfrak{A};\\ \operatorname{std}(f(1),f(2),\ldots,f(n))=\sigma^{-1}}} x_{f(1)}x_{f(2)}\cdots x_{f(n)} = \sum_{\substack{(w_1,w_2,\ldots,w_n)\in\mathfrak{A}^n;\\ \operatorname{std}(w_1,w_2,\ldots,w_n)=\sigma^{-1}}} x_{w_1}x_{w_2}\cdots x_{w_n}.$$

Hence, (13.126.21) becomes

$$L_{\gamma(\sigma)} = \sum_{\substack{f:\{1,2,\ldots,n\}\to\mathfrak{A};\\ \operatorname{std}(f(1),f(2),\ldots,f(n))=\sigma^{-1}}} x_{f(1)}x_{f(2)}\cdots x_{f(n)} = \sum_{\substack{(w_1,w_2,\ldots,w_n)\in\mathfrak{A}^n;\\ \operatorname{std}(w_1,w_2,\ldots,w_n)=\sigma^{-1}}} x_{w_1}x_{w_2}\cdots x_{w_n}.$$

Comparing this with

$$\begin{aligned}
\sum_{\substack{w\in\mathfrak{A}^n;\\ \operatorname{std} w=\sigma^{-1}}} \mathbf{x}_w &= \sum_{\substack{(w_1,w_2,\ldots,w_n)\in\mathfrak{A}^n;\\ \operatorname{std}(w_1,w_2,\ldots,w_n)=\sigma^{-1}}} \underbrace{\mathbf{x}_{(w_1,w_2,\ldots,w_n)}}_{\substack{=x_{w_1}x_{w_2}\cdots x_{w_n}\\ \text{(by the definition of } \mathbf{x}_{(w_1,w_2,\ldots,w_n)})}} \\
&\qquad \text{(here, we have renamed the summation index } w \text{ as } (w_1,w_2,\ldots,w_n)) \\
&= \sum_{\substack{(w_1,w_2,\ldots,w_n)\in\mathfrak{A}^n;\\ \operatorname{std}(w_1,w_2,\ldots,w_n)=\sigma^{-1}}} x_{w_1}x_{w_2}\cdots x_{w_n},
\end{aligned}$$

we obtain $L_{\gamma(\sigma)} = \sum_{\substack{w\in\mathfrak{A}^n;\\ \operatorname{std} w=\sigma^{-1}}} \mathbf{x}_w$. This proves Lemma 5.3.6. □

Proposition 5.3.2 and Lemma 5.3.6 have now been proven. Thus, Exercise 5.3.7 is solved.

13.127. **Solution to Exercise 5.4.5.** *Solution to Exercise 5.4.5.* Consider the power series $\widetilde{H}(t)$ and $\xi(t)$ defined in (5.4.6). From (5.4.6), we know that

$$\sum_{n\geq 1} \xi_n t^n = \log \widetilde{H}(t) = \log\left(\sum_{n\geq 0} H_n t^n\right). \tag{13.127.1}$$

(a) The fact that ξ_n is primitive was proven for $\mathbf{k} = \mathbb{Q}$ in Remark 5.4.4, and can be proven in the same way for general $\mathbf{k}$. It remains to show that ξ_n is homogeneous of degree n for each $n \geq 1$. This can be done as follows:

Let us say that a power series $f \in A[[t]]$ over a graded $\mathbf{k}$-algebra A is *equigraded* if, for every $n \in \mathbb{N}$, the coefficient of f before t^n is homogeneous of degree n. Then, the set of all equigraded power series in $A[[t]]$ is a $\mathbf{k}$-subalgebra of $A[[t]]$ which is closed under the usual topology on $A[[t]]$. In particular, if g is an equigraded power series in $A[[t]]$ having constant term 1, then $\log g$ is equigraded. Applied to $A = \operatorname{NSym}$ and $g = \sum_{n\geq 0} H_n t^n$, this yields that the power series $\log\left(\sum_{n\geq 0} H_n t^n\right)$ is equigraded. Due to (13.127.1), this rewrites as follows: The power series $\sum_{n\geq 1} \xi_n t^n$ is equigraded. In other words, ξ_n is homogeneous of degree n for each $n \geq 1$. This completes the solution of Exercise 5.4.5(a).

For an alternative proof of Exercise 5.4.5(a), one can simply notice that it follows immediately from Exercise 5.4.5(c).

(b) The ring homomorphism $\pi : \operatorname{NSym} \to \Lambda$ induces a ring homomorphism $\operatorname{NSym}[[t]] \to \Lambda[[t]]$ which is continuous with respect to the usual topology on power series. Applying this latter homomorphism to the equality (13.127.1), we obtain

$$\sum_{n\geq 1} \pi(\xi_n) t^n = \log\left(\sum_{n\geq 0} \pi(H_n) t^n\right) = \log\left(\sum_{n\geq 0} h_n t^n\right) = \sum_{m=1}^{\infty} \frac{1}{m} p_m t^m$$

(where in the last step, we have used the equality (2.5.12)). Comparing coefficients, we obtain $\pi(\xi_n) = \frac{1}{n} p_n$ for all $n \geq 1$. Multiplying this by n, we obtain $\pi(n\xi_n) = p_n$ for all $n \geq 1$. This solves part (b) of the exercise.

Remark: Another way to solve Exercise 5.4.5(b) proceeds as follows: We know that $\pi(n\xi_n)$ is a primitive homogeneous element of Λ of degree n (by Exercise 5.4.5(a) and since π is a graded homomorphism of Hopf algebras). But Exercise 3.1.9 shows that all such elements are scalar multiples of p_n. Thus, $\pi(n\xi_n)$ is a scalar multiple of p_n. Finding the scalar is easy (e.g., it can be obtained by specializing at (1)).

(c) From (13.127.1), we have

$$
\begin{aligned}
\sum_{n\geq 1} \xi_n t^n &= \log\left(\underbrace{\sum_{n\geq 0} H_n t^n}_{=1+\sum_{n\geq 1} H_n t^n}\right) = \log\left(1+\sum_{n\geq 1} H_n t^n\right) \\
&= \sum_{i\geq 1} \frac{(-1)^{i-1}}{i} \underbrace{\left(\sum_{n\geq 1} H_n t^n\right)^i}_{=\sum_{n_1,n_2,\ldots,n_i\geq 1}\left(H_{n_1}t^{n_1}\right)\left(H_{n_2}t^{n_2}\right)\cdots\left(H_{n_i}t^{n_i}\right)} \\
&\qquad \text{(by the Mercator series for the logarithm)} \\
&= \sum_{i\geq 1} \frac{(-1)^{i-1}}{i} \underbrace{\sum_{n_1,n_2,\ldots,n_i\geq 1}}_{\substack{=\sum\limits_{\substack{(n_1,n_2,\ldots,n_i) \text{ is a composition} \\ \text{of length } i}}}} \underbrace{\left(H_{n_1}t^{n_1}\right)\left(H_{n_2}t^{n_2}\right)\cdots\left(H_{n_i}t^{n_i}\right)}_{=H_{n_1}H_{n_2}\cdots H_{n_i}t^{n_1+n_2+\cdots+n_i}} \\
&= \sum_{i\geq 1} \frac{(-1)^{i-1}}{i} \sum_{\substack{(n_1,n_2,\ldots,n_i) \text{ is a composition} \\ \text{of length } i}} \underbrace{H_{n_1}H_{n_2}\cdots H_{n_i}}_{=H_{(n_1,n_2,\ldots,n_i)}} \underbrace{t^{n_1+n_2+\cdots+n_i}}_{=t^{\left|(n_1,n_2,\ldots,n_i)\right|}} \\
&= \sum_{i\geq 1} \frac{(-1)^{i-1}}{i} \sum_{\substack{(n_1,n_2,\ldots,n_i) \text{ is a composition} \\ \text{of length } i}} H_{(n_1,n_2,\ldots,n_i)} t^{\left|(n_1,n_2,\ldots,n_i)\right|} \\
&= \sum_{i\geq 1} \frac{(-1)^{i-1}}{i} \sum_{\substack{\alpha \text{ is a composition} \\ \text{of length } i}} H_\alpha t^{|\alpha|} \\
&\qquad \text{(here, we renamed the summation index } (n_1, n_2, \ldots, n_i) \text{ as } \alpha \text{ in the inner sum)} \\
&= \sum_{i\geq 1} \sum_{\substack{\alpha \text{ is a composition} \\ \text{of length } i}} \underbrace{\frac{(-1)^{i-1}}{i}}_{\substack{=\frac{(-1)^{\ell(\alpha)-1}}{\ell(\alpha)} \\ (\text{since } i=\ell(\alpha))}} H_\alpha t^{|\alpha|} = \underbrace{\sum_{i\geq 1} \sum_{\substack{\alpha \text{ is a composition} \\ \text{of length } i}}}_{\substack{=\sum\limits_{\substack{\alpha \text{ is a nonempty} \\ \text{composition}}} \\ =\sum_{n\geq 1}\sum_{\alpha\in\operatorname{Comp}_n}}} \frac{(-1)^{\ell(\alpha)-1}}{\ell(\alpha)} H_\alpha t^{|\alpha|} \\
&= \sum_{n\geq 1} \sum_{\alpha\in\operatorname{Comp}_n} \frac{(-1)^{\ell(\alpha)-1}}{\ell(\alpha)} H_\alpha \underbrace{t^{|\alpha|}}_{\substack{=t^n \\ (\text{since } \alpha\in\operatorname{Comp}_n)}} = \sum_{n\geq 1} \sum_{\alpha\in\operatorname{Comp}_n} \frac{(-1)^{\ell(\alpha)-1}}{\ell(\alpha)} H_\alpha t^n \\
&= \sum_{n\geq 1} \left(\sum_{\alpha\in\operatorname{Comp}_n} \frac{(-1)^{\ell(\alpha)-1}}{\ell(\alpha)} H_\alpha\right) t^n .
\end{aligned}
$$

Comparing coefficients in this identity, we conclude that every $n \geq 1$ satisfies

$$
\xi_n = \sum_{\alpha\in\operatorname{Comp}_n} \frac{(-1)^{\ell(\alpha)-1}}{\ell(\alpha)} H_\alpha = \sum_{\alpha\in\operatorname{Comp}_n} (-1)^{\ell(\alpha)-1} \frac{1}{\ell(\alpha)} H_\alpha .
$$

This solves part (c) of the exercise.

(d) Applying the exponential to $\sum_{n\geq 1}\xi_n t^n = \log H(t)$, we obtain $\exp\left(\sum_{n\geq 1}\xi_n t^n\right) = H(t)$. Thus,

$$H(t) = \exp\left(\sum_{n\geq 1}\xi_n t^n\right) = \sum_{i\geq 0}\frac{1}{i!}\underbrace{\left(\sum_{n\geq 1}\xi_n t^n\right)^i}_{=\sum_{n_1,n_2,\ldots,n_i\geq 1}(\xi_{n_1}t^{n_1})(\xi_{n_2}t^{n_2})\cdots(\xi_{n_i}t^{n_i})}$$

$$= \sum_{i\geq 0}\frac{1}{i!}\underbrace{\sum_{n_1,n_2,\ldots,n_i\geq 1}}_{=\sum_{\substack{(n_1,n_2,\ldots,n_i)\text{ is a composition}\\ \text{of length } i}}}\underbrace{(\xi_{n_1}t^{n_1})(\xi_{n_2}t^{n_2})\cdots(\xi_{n_i}t^{n_i})}_{=\xi_{n_1}\xi_{n_2}\cdots\xi_{n_i}t^{n_1+n_2+\cdots+n_i}}$$

$$= \sum_{i\geq 0}\frac{1}{i!}\sum_{\substack{(n_1,n_2,\ldots,n_i)\text{ is a composition}\\ \text{of length } i}}\underbrace{\xi_{n_1}\xi_{n_2}\cdots\xi_{n_i}}_{\substack{=\xi_{(n_1,n_2,\ldots,n_i)}\\ \text{(because we defined }\xi_{(n_1,n_2,\ldots,n_i)}\\ \text{in such a way that this holds)}}}\underbrace{t^{n_1+n_2+\ldots+n_i}}_{=t^{|(n_1,n_2,\ldots,n_i)|}}$$

$$= \sum_{i\geq 0}\frac{1}{i!}\sum_{\substack{(n_1,n_2,\ldots,n_i)\text{ is a composition}\\ \text{of length } i}}\xi_{(n_1,n_2,\ldots,n_i)}t^{|(n_1,n_2,\ldots,n_i)|} = \sum_{i\geq 0}\frac{1}{i!}\sum_{\substack{\alpha\text{ is a composition}\\ \text{of length } i}}\xi_\alpha t^{|\alpha|}$$

$$\text{(here, we renamed the summation index } (n_1,n_2,\ldots,n_i) \text{ as } \alpha \text{ in the inner sum)}$$

$$= \sum_{i\geq 0}\sum_{\substack{\alpha\text{ is a composition}\\ \text{of length } i}}\underbrace{\frac{1}{i!}}_{\substack{=\frac{1}{\ell(\alpha)!}\\ \text{(since } i=\ell(\alpha))}}\xi_\alpha t^{|\alpha|} = \underbrace{\sum_{i\geq 0}\sum_{\substack{\alpha\text{ is a composition}\\ \text{of length } i}}}_{\substack{=\sum_{\alpha\text{ is a composition}}\\ =\sum_{n\geq 0}\sum_{\alpha\in\mathrm{Comp}_n}}}\frac{1}{\ell(\alpha)!}\xi_\alpha t^{|\alpha|}$$

$$= \sum_{n\geq 0}\sum_{\alpha\in\mathrm{Comp}_n}\frac{1}{\ell(\alpha)!}\xi_\alpha\underbrace{t^{|\alpha|}}_{\substack{=t^n\\ \text{(since } \alpha\in\mathrm{Comp}_n\text{)}}} = \sum_{n\geq 0}\sum_{\alpha\in\mathrm{Comp}_n}\frac{1}{\ell(\alpha)!}\xi_\alpha t^n = \sum_{n\geq 0}\left(\sum_{\alpha\in\mathrm{Comp}_n}\frac{1}{\ell(\alpha)!}\xi_\alpha\right)t^n.$$

Comparing coefficients in this identity, we conclude that every $n\geq 0$ satisfies

$$H_n = \sum_{\alpha\in\mathrm{Comp}_n}\frac{1}{\ell(\alpha)!}\xi_\alpha$$

(since the coefficient of t^n in $H(t)$ is H_n). This proves (5.4.8).

Notice that, for every $n\geq 1$, the element ξ_n of NSym is homogeneous of degree n (by Exercise 5.4.5(a)). Hence, for every composition α, the element ξ_α of NSym is homogeneous of degree $|\alpha|$. In particular, for every $n\in\mathbb{N}$, it is clear that $(\xi_\alpha)_{\alpha\in\mathrm{Comp}_n}$ is a family of elements of NSym_n. We now need to prove that this family is a $\mathbf{k}$-basis of NSym_n for every $n\in\mathbb{N}$.

Let $\mathfrak{A}$ be the $\mathbf{k}$-subalgebra of NSym generated by the elements ξ_1, ξ_2, ξ_3, ... Then, $\mathfrak{A}$ contains ξ_α for every composition α (by the definition of ξ_α). Therefore, $\mathfrak{A}$ contains H_n for every $n\geq 1$ (by (5.4.7)). Consequently, $\mathfrak{A} = \mathrm{NSym}$ (because NSym is generated as a $\mathbf{k}$-algebra by H_1, H_2, H_3, ...). In other words, the $\mathbf{k}$-algebra NSym is generated by the elements ξ_1, ξ_2, ξ_3, ... (since we defined $\mathfrak{A}$ as the $\mathbf{k}$-subalgebra of NSym generated by the elements ξ_1, ξ_2, ξ_3, ...). In other words, the $\mathbf{k}$-module NSym is spanned by all possible products of the elements ξ_1, ξ_2, ξ_3, ... In other words, the $\mathbf{k}$-module NSym is spanned by the elements ξ_α with $\alpha\in\mathrm{Comp}$ (because the elements ξ_α with $\alpha\in\mathrm{Comp}$ are precisely all possible products of the elements ξ_1, ξ_2, ξ_3, ...). In yet other words, the family $(\xi_\alpha)_{\alpha\in\mathrm{Comp}}$ spans the $\mathbf{k}$-module NSym.

Now, fix $n\in\mathbb{N}$. Every element of NSym_n can be written as a $\mathbf{k}$-linear combination of the elements ξ_α with $\alpha\in\mathrm{Comp}$ (since the family $(\xi_\alpha)_{\alpha\in\mathrm{Comp}}$ spans the $\mathbf{k}$-module NSym). In this $\mathbf{k}$-linear combination, we can remove all terms ξ_α with $\alpha\notin\mathrm{Comp}_n$ without changing the result (by gradedness, because ξ_α is homogeneous of degree $|\alpha|$), and so we conclude that every element of NSym_n can be written as a $\mathbf{k}$-linear combination of the elements ξ_α with $\alpha\in\mathrm{Comp}_n$. In other words, the family $(\xi_\alpha)_{\alpha\in\mathrm{Comp}_n}$ spans the $\mathbf{k}$-module NSym_n.

Now, we can apply Exercise 2.5.18(b) to $A = \operatorname{NSym}_n$, $I = \operatorname{Comp}_n$, $(\gamma_i)_{i\in I} = (H_\alpha)_{\alpha\in\operatorname{Comp}_n}$ and $(\beta_i)_{i\in I} = (\xi_\alpha)_{\alpha\in\operatorname{Comp}_n}$ (since we know that $(H_\alpha)_{\alpha\in\operatorname{Comp}_n}$ is a $\mathbf{k}$-basis of NSym_n, whereas $(\xi_\alpha)_{\alpha\in\operatorname{Comp}_n}$ spans the $\mathbf{k}$-module NSym_n). We conclude that $(\xi_\alpha)_{\alpha\in\operatorname{Comp}_n}$ is a $\mathbf{k}$-basis of NSym_n. Thus, Exercise 5.4.5(d) is solved.

13.128. **Solution to Exercise 5.4.6.** *Solution to Exercise 5.4.6.* We follow the hint.

Let f be the endomorphism $\operatorname{id}_A - u\epsilon$ of A. Then, $f = \sum_{n\geq 1}\pi_n$ (because the definition of the π_n yields that $\operatorname{id}_A = \sum_{n\geq 0}\pi_n = \underbrace{\pi_0}_{=u\epsilon} + \sum_{n\geq 1}\pi_n = u\epsilon + \sum_{n\geq 1}\pi_n$ and thus $\operatorname{id}_A - u\epsilon = \sum_{n\geq 1}\pi_n$). Notice that $f = \operatorname{id}_A - u\epsilon$, so that $\operatorname{id}_A = f + u\epsilon$. Now, $\mathfrak{e} = \log^\star\left(\underbrace{\operatorname{id}_A}_{=f+u\epsilon}\right) = \log^\star(f+u\epsilon) = \sum_{n\geq 1}(-1)^{n-1}\frac{1}{n}f^{\star n}$.

We let $\operatorname{End}_{\mathrm{gr}} A$ be the $\mathbf{k}$-submodule of $\operatorname{End} A$ consisting of all graded $\mathbf{k}$-linear maps $A \to A$. Then, it is easy to see that this $\mathbf{k}$-submodule $\operatorname{End}_{\mathrm{gr}} A$ is closed under convolution (i.e., if g_1 and g_2 are two graded $\mathbf{k}$-linear maps $A \to A$, then $g_1 \star g_2$ is also a graded $\mathbf{k}$-linear map $A \to A$) and contains the unity $u\epsilon$ of the algebra $(\operatorname{End} A, \star)$ (since $u\epsilon : A \to A$ is a graded $\mathbf{k}$-linear map). Hence, $(\operatorname{End}_{\mathrm{gr}} A, \star)$ is a $\mathbf{k}$-subalgebra of $(\operatorname{End} A, \star)$. Moreover, $(\operatorname{End}_{\mathrm{gr}} A, \star)$ contains π_n for every $n \geq 1$. Hence, the $\mathbf{k}$-algebra homomorphism $\mathfrak{W} : \operatorname{NSym} \to (\operatorname{End} A, \star)$ maps the generators H_n of NSym to elements of $(\operatorname{End}_{\mathrm{gr}} A, \star)$. Thus, the image of $\mathfrak{W}$ is contained in $(\operatorname{End}_{\mathrm{gr}} A, \star)$. In other words,

$$\mathfrak{W}(x) \in \operatorname{End}_{\mathrm{gr}} A \qquad \text{for every } x \in \operatorname{NSym}. \tag{13.128.1}$$

It is immediate to check that the $\mathbf{k}$-subalgebra $(\operatorname{End}_{\mathrm{gr}} A, \star)$ of $(\operatorname{End} A, \star)$ is closed under the topology of pointwise convergence. Hence, it is closed under taking logarithms. In other words, $\log^\star g \in \operatorname{End}_{\mathrm{gr}} A$ for every $g \in \operatorname{End}_{\mathrm{gr}} A$ for which $\log^\star g$ makes sense. Applied to $g = \operatorname{id}_A$, this yields that $\log^\star(\operatorname{id}_A) \in \operatorname{End}_{\mathrm{gr}} A$ (since $\operatorname{id}_A \in \operatorname{End}_{\mathrm{gr}} A$). Since $\log^\star(\operatorname{id}_A) = \mathfrak{e}$, this yields that $\mathfrak{e} \in \operatorname{End}_{\mathrm{gr}} A$. In other words, $\mathfrak{e}$ is a graded $\mathbf{k}$-linear map. The definition of $\mathfrak{e}_n$ is legitimate because the gradedness of $\mathfrak{e}$ yields $\pi_n \circ \mathfrak{e} = \mathfrak{e} \circ \pi_n$. This solves Exercise 5.4.6(a).

We notice for future use the fact that $\mathfrak{e}_0 = 0$ [914].

We also record the fact that

$$\Delta_A \circ \pi_n = \left(\sum_{k=0}^{n} \pi_k \otimes \pi_{n-k}\right) \circ \Delta_A \qquad \text{for all } n \in \mathbb{N}. \tag{13.128.2}$$

(This follows by checking that both sides of (13.128.2) are equal to Δ_A on the n-th homogeneous component A_n, while vanishing on all other components[915].)

[914] *Proof.* The definition of $\mathfrak{e}_0$ yields $\mathfrak{e}_0 = \pi_0 \circ \mathfrak{e} = \mathfrak{e} \circ \pi_0$. Thus, $\mathfrak{e}_0(A) = (\mathfrak{e} \circ \pi_0)(A) = \mathfrak{e}\left(\underbrace{\pi_0(A)}_{=\mathbf{k}\cdot 1_A}\right) = \mathfrak{e}(\mathbf{k}\cdot 1_A) = \mathbf{k}\cdot\mathfrak{e}(1_A)$. But every $n \geq 1$ satisfies $f^{\star n}(1_A) = 0$ (since $\Delta^{(n-1)}(1_A) = \underbrace{1_A \otimes 1_A \otimes \ldots \otimes 1_A}_{n \text{ times}}$ and $f(1_A) = 0$). Since $\mathfrak{e} = \sum_{n\geq 1}(-1)^{n-1}\frac{1}{n}f^{\star n}$, we have

$$\mathfrak{e}(1_A) = \left(\sum_{n\geq 1}(-1)^{n-1}\frac{1}{n}f^{\star n}\right)(1_A) = \sum_{n\geq 1}(-1)^{n-1}\frac{1}{n}\underbrace{f^{\star n}(1_A)}_{=0} = \sum_{n\geq 1}(-1)^{n-1}\frac{1}{n}0 = 0.$$

Now, $\mathfrak{e}_0(A) = \mathbf{k}\cdot\underbrace{\mathfrak{e}(1_A)}_{=0} = 0$, so that $\mathfrak{e}_0 = 0$, qed.

[915] And this is because Δ_A is graded.

(b) From (13.127.1), we have

$$\begin{aligned}\sum_{n\geq 1}\xi_n t^n &= \log\left(\sum_{n\geq 0}H_n t^n\right) = \log\left(1+\sum_{n\geq 1}H_n t^n\right)\\ &= \sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\underbrace{\left(\sum_{n\geq 1}H_n t^n\right)^i}_{=\sum_{n_1,n_2,\ldots,n_i\geq 1}H_{n_1}H_{n_2}\ldots H_{n_i}t^{n_1+n_2+\ldots+n_i}} \qquad \text{(by the Mercator series for the logarithm)}\\ &= \sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\sum_{n_1,n_2,\ldots,n_i\geq 1}H_{n_1}H_{n_2}\ldots H_{n_i}t^{n_1+n_2+\ldots+n_i}\\ &= \sum_{n\geq 1}\sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\sum_{\substack{n_1,n_2,\ldots,n_i\geq 1;\\ n_1+n_2+\ldots+n_i=n}}H_{n_1}H_{n_2}\ldots H_{n_i}t^n\end{aligned}$$

in the power series ring $\operatorname{NSym}[[t]]$. Comparing coefficients in this equality, we obtain

$$\xi_n = \sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\sum_{\substack{n_1,n_2,\ldots,n_i\geq 1;\\ n_1+n_2+\ldots+n_i=n}}H_{n_1}H_{n_2}\ldots H_{n_i} \tag{13.128.3}$$

for every $n\geq 1$. Hence, every $n\geq 1$ satisfies

$$\begin{aligned}\mathfrak{W}(\xi_n) &= \mathfrak{W}\left(\sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\sum_{\substack{n_1,n_2,\ldots,n_i\geq 1;\\ n_1+n_2+\ldots+n_i=n}}H_{n_1}H_{n_2}\ldots H_{n_i}\right)\\ &= \sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\sum_{\substack{n_1,n_2,\ldots,n_i\geq 1;\\ n_1+n_2+\ldots+n_i=n}}\mathfrak{W}(H_{n_1})\star\mathfrak{W}(H_{n_2})\star\ldots\star\mathfrak{W}(H_{n_i})\\ &\qquad \text{(since }\mathfrak{W}\text{ is a }\mathbf{k}\text{-algebra homomorphism)}\\ &= \sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\sum_{\substack{n_1,n_2,\ldots,n_i\geq 1;\\ n_1+n_2+\ldots+n_i=n}}\pi_{n_1}\star\pi_{n_2}\star\ldots\star\pi_{n_i} \qquad (13.128.4)\end{aligned}$$

(since $\mathfrak{W}$ maps every H_m to π_m).

On the other hand, $f=\sum_{n\geq 1}\pi_n$. Thus,

$$f^{\star i} = \left(\sum_{n\geq 1}\pi_n\right)^{\star i} = \sum_{n_1,n_2,\ldots,n_i\geq 1}\pi_{n_1}\star\pi_{n_2}\star\ldots\star\pi_{n_i}$$

for every $i\in\mathbb{N}$. Now,

$$\begin{aligned}\mathfrak{e} &= \sum_{n\geq 1}(-1)^{n-1}\frac{1}{n}f^{\star n} = \sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\underbrace{f^{\star i}}_{=\sum_{n_1,n_2,\ldots,n_i\geq 1}\pi_{n_1}\star\pi_{n_2}\star\ldots\star\pi_{n_i}}\\ &= \sum_{i\geq 1}(-1)^{i-1}\frac{1}{i}\sum_{n_1,n_2,\ldots,n_i\geq 1}\pi_{n_1}\star\pi_{n_2}\star\ldots\star\pi_{n_i}. \qquad (13.128.5)\end{aligned}$$

Now,

$$\begin{aligned}
\mathfrak{e}_n &= \pi_n \circ \mathfrak{e} \\
&= \pi_n \circ \left(\sum_{i\geq 1} (-1)^{i-1} \frac{1}{i} \sum_{n_1, n_2, \ldots, n_i \geq 1} \pi_{n_1} \star \pi_{n_2} \star \ldots \star \pi_{n_i} \right) \qquad \text{(by (13.128.5))} \\
&= \sum_{i\geq 1} (-1)^{i-1} \frac{1}{i} \sum_{n_1, n_2, \ldots, n_i \geq 1} \pi_n \circ \left(\pi_{n_1} \star \pi_{n_2} \star \ldots \star \pi_{n_i} \right) \\
&= \underbrace{\sum_{i\geq 1} (-1)^{i-1} \frac{1}{i} \sum_{\substack{n_1, n_2, \ldots, n_i \geq 1; \\ n_1+n_2+\ldots+n_i = n}} \pi_n \circ \left(\pi_{n_1} \star \pi_{n_2} \star \ldots \star \pi_{n_i} \right)}_{\substack{=\mathfrak{W}(\xi_n) \\ \text{(by (13.128.4))}}} \\
&\qquad + \sum_{i\geq 1} (-1)^{i-1} \frac{1}{i} \sum_{\substack{n_1, n_2, \ldots, n_i \geq 1; \\ n_1+n_2+\ldots+n_i \neq n}} \underbrace{\pi_n \circ \left(\pi_{n_1} \star \pi_{n_2} \star \ldots \star \pi_{n_i} \right)}_{\substack{=0 \\ \text{(because the image of} \\ \pi_{n_1} \star \pi_{n_2} \star \ldots \star \pi_{n_i} = m^{(i-1)} \circ \left(\pi_{n_1} \otimes \pi_{n_2} \otimes \ldots \otimes \pi_{n_i} \right) \circ \Delta^{(i-1)} \\ \text{is contained in} \\ m^{(i-1)} \left(\left(\pi_{n_1} \otimes \pi_{n_2} \otimes \ldots \otimes \pi_{n_i} \right) \left(A^{\otimes i} \right) \right) = A_{n_1} A_{n_2} \ldots A_{n_i} \subset A_{n_1+n_2+\ldots+n_i}, \\ \text{which is a different homogeneous component of } A \text{ than } A_n \text{)}}} \\
&= \mathfrak{W}\left(\xi_n\right) + \underbrace{\sum_{i\geq 1} (-1)^{i-1} \frac{1}{i} \sum_{\substack{n_1, n_2, \ldots, n_i \geq 1; \\ n_1+n_2+\ldots+n_i \neq n}} 0}_{=0} = \mathfrak{W}\left(\xi_n\right).
\end{aligned}$$

This solves Exercise 5.4.6(b).

(c) Exercise 1.5.6(a) (applied to $C = A$) yields that the comultiplication $\Delta_A : A \to A \otimes A$ is a **k**-coalgebra homomorphism (since A is cocommutative). Also, the comultiplications Δ_A and Δ_{NSym} are **k**-algebra homomorphisms (as is the comultiplication of any **k**-bialgebra).

Let R be the **k**-linear map $(\operatorname{End} A, \star) \otimes (\operatorname{End} A, \star) \to (\operatorname{End}(A \otimes A), \star)$ which sends every tensor $f \otimes g \in (\operatorname{End} A, \star) \otimes (\operatorname{End} A, \star)$ to the map $f \otimes g : A \otimes A \to A \otimes A$. This map R is a **k**-algebra homomorphism[916].

Let Ω_1 be the composition

$$\mathrm{NSym} \xrightarrow{\mathfrak{W}} (\operatorname{End} A, \star) \xrightarrow{\operatorname{post}(\Delta_A)} (\operatorname{Hom}(A, A \otimes A), \star),$$

where $\operatorname{post}(\Delta_A)$ denotes the **k**-linear map sending every $\gamma \in (\operatorname{End} A, \star)$ to $\Delta_A \circ \gamma \in (\operatorname{Hom}(A, A \otimes A), \star)$. Since the map $\mathfrak{W}$ is a **k**-algebra homomorphism, and since the map $\operatorname{post}(\Delta_A)$ is a **k**-algebra homomorphism[917], their composition Ω_1 also is a **k**-algebra homomorphism.

Let Ω_2 be the composition

$$\mathrm{NSym} \xrightarrow{\Delta_{\mathrm{NSym}}} \mathrm{NSym} \otimes \mathrm{NSym} \xrightarrow{\mathfrak{W} \otimes \mathfrak{W}} (\operatorname{End} A, \star) \otimes (\operatorname{End} A, \star) \xrightarrow{R} (\operatorname{End}(A \otimes A), \star) \xrightarrow{\operatorname{pre}(\Delta_A)} (\operatorname{Hom}(A, A \otimes A), \star),$$

where $\operatorname{pre}(\Delta_A)$ denotes the **k**-linear map sending every $\gamma \in (\operatorname{End}(A \otimes A), \star)$ to $\gamma \circ \Delta_A \in (\operatorname{Hom}(A, A \otimes A), \star)$. Since the maps Δ_{NSym}, $\mathfrak{W} \otimes \mathfrak{W}$ and R are **k**-algebra homomorphisms, and since the map $\operatorname{pre}(\Delta_A)$ is a **k**-algebra homomorphism[918], their composition Ω_2 also is a **k**-algebra homomorphism.

In order to solve Exercise 5.4.6(c), we need to show that every $w \in \mathrm{NSym}$ satisfies $\Delta \circ (\mathfrak{W}(w)) = \left(\sum_{(w)} \mathfrak{W}(w_1) \otimes \mathfrak{W}(w_2) \right) \circ \Delta$. Since

$$\Delta \circ (\mathfrak{W}(w)) = \Delta_A \circ (\mathfrak{W}(w)) = (\operatorname{post}(\Delta_A))(\mathfrak{W}(w)) = \underbrace{(\operatorname{post}(\Delta_A) \circ \mathfrak{W})}_{=\Omega_1}(w) = \Omega_1(w)$$

[916] In fact, this is a particular case of Exercise 1.4.4(b).

[917] This follows from Proposition 1.4.3 (applied to A, A, A, $A \otimes A$, id_A and Δ_A instead of C, C', A, A', γ and α) (because we know that Δ_A is a **k**-algebra homomorphism).

[918] This follows from Proposition 1.4.3 (applied to A, $A \otimes A$, $A \otimes A$, $A \otimes A$, Δ_A and $\mathrm{id}_{A \otimes A}$ instead of C, C', A, A', γ and α) (because we know that Δ_A is a **k**-coalgebra homomorphism).

and

$$\begin{aligned}\underbrace{\left(\sum_{(w)}\mathfrak{W}(w_1)\otimes\mathfrak{W}(w_2)\right)}_{=R((\mathfrak{W}\otimes\mathfrak{W})(\Delta_{\mathrm{NSym}}(w)))}\circ\underbrace{\Delta}_{=\Delta_A} &= \left(R\left((\mathfrak{W}\otimes\mathfrak{W})(\Delta_{\mathrm{NSym}}(w))\right)\right)\circ\Delta_A \\ &= (\operatorname{pre}(\Delta_A))\left(R\left((\mathfrak{W}\otimes\mathfrak{W})(\Delta_{\mathrm{NSym}}(w))\right)\right) \\ &= \underbrace{(\operatorname{pre}(\Delta_A)\circ R\circ(\mathfrak{W}\otimes\mathfrak{W})\circ\Delta_{\mathrm{NSym}})}_{=\Omega_2}(w)=\Omega_2(w),\end{aligned}$$

this is equivalent to showing that every $w\in\mathrm{NSym}$ satisfies $\Omega_1(w)=\Omega_2(w)$. In other words, we need to prove that $\Omega_1=\Omega_2$. Since Ω_1 and Ω_2 are $\mathbf{k}$-algebra homomorphisms, it will be enough to verify this on the generators $H_1,H_2,H_3,\ldots$ of the $\mathbf{k}$-algebra NSym. But on said generators, this is easily seen to hold, because every $n\geq 1$ satisfies

$$\begin{aligned}\Omega_1(H_n) &= (\operatorname{post}(\Delta_A)\circ\mathfrak{W})(H_n)=(\operatorname{post}(\Delta_A))\left(\underbrace{\mathfrak{W}(H_n)}_{=\pi_n}\right) \\ &= (\operatorname{post}(\Delta_A))(\pi_n)=\Delta_A\circ\pi_n=\left(\sum_{k=0}^{n}\pi_k\otimes\pi_{n-k}\right)\circ\Delta_A \qquad (\text{by } (13.128.2))\end{aligned}$$

and

$$\begin{aligned}\Omega_2(H_n) &= (\operatorname{pre}(\Delta_A)\circ R\circ(\mathfrak{W}\otimes\mathfrak{W})\circ\Delta_{\mathrm{NSym}})(H_n) \\ &= (\operatorname{pre}(\Delta_A)\circ R\circ(\mathfrak{W}\otimes\mathfrak{W}))\left(\underbrace{\Delta_{\mathrm{NSym}}(H_n)}_{=\sum_{k=0}^{n}H_k\otimes H_{n-k}}\right) \\ &= (\operatorname{pre}(\Delta_A)\circ R\circ(\mathfrak{W}\otimes\mathfrak{W}))\left(\sum_{k=0}^{n}H_k\otimes H_{n-k}\right) \\ &= (\operatorname{pre}(\Delta_A)\circ R)\left((\mathfrak{W}\otimes\mathfrak{W})\left(\sum_{k=0}^{n}H_k\otimes H_{n-k}\right)\right) \\ &= (\operatorname{pre}(\Delta_A)\circ R)\left(\sum_{k=0}^{n}\underbrace{\mathfrak{W}(H_k)}_{=\pi_k}\otimes\underbrace{\mathfrak{W}(H_{n-k})}_{=\pi_{n-k}}\right) \\ &= (\operatorname{pre}(\Delta_A)\circ R)\left(\sum_{k=0}^{n}\pi_k\otimes\pi_{n-k}\right) \\ &= (\operatorname{pre}(\Delta_A))\left(R\left(\sum_{k=0}^{n}\pi_k\otimes\pi_{n-k}\right)\right)=\underbrace{R\left(\sum_{k=0}^{n}\pi_k\otimes\pi_{n-k}\right)}_{=\sum_{k=0}^{n}\pi_k\otimes\pi_{n-k}}\circ\Delta_A \\ &= \left(\sum_{k=0}^{n}\pi_k\otimes\pi_{n-k}\right)\circ\Delta_A.\end{aligned}$$

Exercise 5.4.6(c) is proven.

(d) Let $n\geq 0$. We need to prove that $\mathfrak{e}_n(A)\subset\mathfrak{p}$. If $n=0$, then this is clear because $\mathfrak{e}_0=0$. Hence, we assume WLOG that we don't have $n=0$. Thus, $n\geq 1$. Hence, Exercise 5.4.5(a) yields that ξ_n is primitive, so that $\Delta(\xi_n)=\xi_n\otimes 1+1\otimes\xi_n$.

Applying Exercise 5.4.6(c) to $w = \xi_n$, we obtain

$$\begin{aligned}\Delta \circ (\mathfrak{W}(\xi_n)) &= \left(\sum_{(\xi_n)} \mathfrak{W}((\xi_n)_1) \otimes \mathfrak{W}((\xi_n)_2) \right) \circ \Delta \\ &= (\mathfrak{W}(\xi_n) \otimes \mathfrak{W}(1) + \mathfrak{W}(1) \otimes \mathfrak{W}(\xi_n)) \circ \Delta \\ &\qquad \left(\text{since } \sum_{(\xi_n)} (\xi_n)_1 \otimes (\xi_n)_2 = \Delta(\xi_n) = \xi_n \otimes 1 + 1 \otimes \xi_n \right).\end{aligned}$$

Since $\mathfrak{W}(1) = u\epsilon$ and $\mathfrak{W}(\xi_n) = \mathfrak{e}_n$, this rewrites as

$$\Delta \circ \mathfrak{e}_n = (\mathfrak{e}_n \otimes (u\epsilon) + (u\epsilon) \otimes \mathfrak{e}_n) \circ \Delta.$$

Now, let $x \in A$. Then,

$$\begin{aligned}\Delta(\mathfrak{e}_n(x)) &= \underbrace{(\Delta \circ \mathfrak{e}_n)}_{=(\mathfrak{e}_n \otimes (u\epsilon) + (u\epsilon) \otimes \mathfrak{e}_n) \circ \Delta} (x) = ((\mathfrak{e}_n \otimes (u\epsilon) + (u\epsilon) \otimes \mathfrak{e}_n) \circ \Delta)(x) \\ &= (\mathfrak{e}_n \otimes (u\epsilon))(\Delta(x)) + ((u\epsilon) \otimes \mathfrak{e}_n)(\Delta(x)) \\ &= \sum_{(x)} \mathfrak{e}_n(x_1) \otimes \underbrace{(u\epsilon)(x_2)}_{=1_A \epsilon(x_2)} + \sum_{(x)} \underbrace{(u\epsilon)(x_1)}_{=1_A \epsilon(x_1)} \otimes \mathfrak{e}_n(x_2) \\ &= \sum_{(x)} \mathfrak{e}_n(x_1) \otimes 1_A \epsilon(x_2) + \sum_{(x)} 1_A \epsilon(x_1) \otimes \mathfrak{e}_n(x_2) \\ &= \mathfrak{e}_n \left(\underbrace{\sum_{(x)} x_1 \epsilon(x_2)}_{=x} \right) \otimes 1_A + 1_A \otimes \mathfrak{e}_n \left(\underbrace{\sum_{(x)} \epsilon(x_1) x_2}_{=x} \right) \\ &= \mathfrak{e}_n(x) \otimes 1_A + 1_A \otimes \mathfrak{e}_n(x).\end{aligned}$$

Hence, $\mathfrak{e}_n(x)$ is a primitive element of A; thus, $\mathfrak{e}_n(x) \in \mathfrak{p}$. Forget now that we fixed x. We thus have seen that every $x \in A$ satisfies $\mathfrak{e}_n(x) \in \mathfrak{p}$. In other words, $\mathfrak{e}_n(A) \subset \mathfrak{p}$. This solves Exercise 5.4.6(d).

(e) Every $n \geq 0$ satisfies $\mathfrak{e}_n(A) \subset \mathfrak{p}$ (by Exercise 5.4.6(d)).

We have $\operatorname{id}_A = \sum_{n \geq 0} \pi_n$ (by the definition of π_n), and

$$\mathfrak{e} = \underbrace{\operatorname{id}_A}_{=\sum_{n \geq 0} \pi_n} \circ \mathfrak{e} = \sum_{n \geq 0} \underbrace{\pi_n \circ \mathfrak{e}}_{\substack{=\mathfrak{e}_n \\ \text{(since the definition of } \mathfrak{e}_n \\ \text{yields } \mathfrak{e}_n = \pi_n \circ \mathfrak{e})}} = \sum_{n \geq 0} \mathfrak{e}_n.$$

Hence, $\mathfrak{e}(A) = \left(\sum_{n \geq 0} \mathfrak{e}_n \right)(A) \subset \sum_{n \geq 0} \underbrace{\mathfrak{e}_n(A)}_{\subset \mathfrak{p}} \subset \sum_{n \geq 0} \mathfrak{p} \subset \mathfrak{p}$. This proves part (e) of the exercise.

(f) Let $x \in \mathfrak{p}$. Then, $\Delta(x) = x \otimes 1_A + 1_A \otimes x$.

Let $\mathfrak{g}(A, A)$ denote the $\mathbf{k}$-submodule of $\operatorname{End} A$ which consists of all $g \in \operatorname{End} A$ satisfying $g(1_A) = 0$. Then, it is easy to see that $\mathfrak{g}(A, A)$ is an ideal of the algebra $(\operatorname{End} A, \star)$ (indeed, any $g_1 \in \operatorname{End} A$ and $g_2 \in \mathfrak{g}(A, A)$ satisfy $g_1 \star g_2 \in \mathfrak{g}(A, A)$ and $g_2 \star g_1 \in \mathfrak{g}(A, A)$). We have $f \in \mathfrak{g}(A, A)$. Since $\mathfrak{g}(A, A)$ is an ideal of $(\operatorname{End} A, \star)$, this yields that every $n \geq 2$ satisfies $f^{\star n} \in (\mathfrak{g}(A, A))^{\star 2}$ (where $I^{\star 2}$ denotes the square of the ideal I for any ideal I of the $\mathbf{k}$-algebra $(\operatorname{End} A, \star)$). But it is easy to see that

$$g(x) = 0 \qquad \text{for every } g \in (\mathfrak{g}(A, A))^{\star 2}. \tag{13.128.6}$$

[919] In particular, this yields that

$$f^{\star n}(x) = 0 \qquad \text{for every } n \geq 2 \tag{13.128.7}$$

(since $f^{\star n} \in (\mathfrak{g}(A,A))^{\star 2}$ for every $n \geq 2$). Now, $\mathfrak{e} = \sum_{n \geq 1} (-1)^{n-1} \frac{1}{n} f^{\star n}$, so that

$$\begin{aligned}
\mathfrak{e}(x) &= \left(\sum_{n \geq 1} (-1)^{n-1} \frac{1}{n} f^{\star n} \right)(x) = \sum_{n \geq 1} (-1)^{n-1} \frac{1}{n} f^{\star n}(x) \\
&= \underbrace{(-1)^{1-1} \frac{1}{1}}_{=1} \underbrace{f^{\star 1}}_{=f = \operatorname{id}_A - u\epsilon} (x) + \sum_{n \geq 2} (-1)^{n-1} \frac{1}{n} \underbrace{f^{\star n}(x)}_{\substack{=0 \\ \text{(by (13.128.7))}}} \\
&= (\operatorname{id}_A - u\epsilon)(x) + \underbrace{\sum_{n \geq 2} (-1)^{n-1} \frac{1}{n} 0}_{=0} = (\operatorname{id}_A - u\epsilon)(x) = x - u \left(\underbrace{\epsilon(x)}_{\substack{=0 \\ \text{(by Proposition 1.4.17)}}} \right) = x - \underbrace{u(0)}_{=0} = x.
\end{aligned}$$

Now, forget that we fixed x. We thus have shown that $\mathfrak{e}(x) = x$ for every $x \in \mathfrak{p}$. In other words, the map $\mathfrak{e}$ fixes any element of $\mathfrak{p}$. This solves Exercise 5.4.6(f).

Combining the results of parts (e) and (f) of Exercise 5.4.6, we conclude that $\mathfrak{e}$ is a projection from A to the $\mathbf{k}$-submodule $\mathfrak{p}$. This completes the solution of the exercise.

13.129. **Solution to Exercise 5.4.8.** *Solution to Exercise 5.4.8.* Let us first show the following two lemmas, which have nothing to do with Hopf algebras:

Lemma 13.129.1. *Let V be any torsionfree abelian group (written additively). Let $N \in \mathbb{N}$. For every $k \in \{0, 1, ..., N\}$, let w_k be an element of V. Assume that*

$$\sum_{k=0}^{N} w_k n^k = 0 \qquad \text{for all } n \in \mathbb{N}. \tag{13.129.1}$$

Then, $w_k = 0$ for every $k \in \{0, 1, ..., N\}$.

Lemma 13.129.2. *Let V be any torsionfree abelian group (written additively). Let $N \in \mathbb{N}$. For every $(k, \ell) \in \{0, 1, ..., N\}^2$, let $v_{k,\ell}$ be an element of V. Assume that*

$$\sum_{k=0}^{N} \sum_{\ell=0}^{N} v_{k,\ell} n^k m^\ell = 0 \qquad \text{for all } n \in \mathbb{N} \text{ and } m \in \mathbb{N}. \tag{13.129.2}$$

Then, $v_{k,\ell} = 0$ for every $(k, \ell) \in \{0, 1, ..., N\}^2$.

Proof of Lemma 13.129.1. Lemma 13.129.1 has already appeared above (namely, as Lemma 1.7.24), and has already been proven (in the solution to Exercise 1.7.28). □

Proof of Lemma 13.129.2. Fix $m \in \mathbb{N}$. Every $n \in \mathbb{N}$ satisfies

$$\sum_{k=0}^{N} \left(\sum_{\ell=0}^{N} v_{k,\ell} m^\ell \right) n^k = \sum_{k=0}^{N} \sum_{\ell=0}^{N} v_{k,\ell} n^k m^\ell = 0.$$

Thus, Lemma 13.129.1 (applied to $w_k = \sum_{\ell=0}^{N} v_{k,\ell} m^\ell$) yields that $\sum_{\ell=0}^{N} v_{k,\ell} m^\ell = 0$ for every $k \in \{0, 1, ..., N\}$.

[919] *Proof of* (13.128.6)*:* It is clearly enough to check that $(g_1 \star g_2)(x) = 0$ for every $g_1 \in \mathfrak{g}(A,A)$ and $g_2 \in \mathfrak{g}(A,A)$. But this is easy: If $g_1 \in \mathfrak{g}(A,A)$ and $g_2 \in \mathfrak{g}(A,A)$, then $g_1(1_A) = 0$ and $g_2(1_A) = 0$, so that

$$\begin{aligned}
(g_1 \star g_2)(x) &= g_1(x) \underbrace{g_2(1_A)}_{=0} + \underbrace{g_1(1_A)}_{=0} g_2(x) \qquad (\text{since } \Delta(x) = x \otimes 1_A + 1_A \otimes x) \\
&= 0 + 0 = 0.
\end{aligned}$$

This proves (13.128.6).

Now, forget that we fixed m. We thus have proven that

$$\sum_{\ell=0}^{N} v_{k,\ell} m^{\ell} = 0 \qquad \text{for every } m \in \mathbb{N} \text{ and } k \in \{0,1,...,N\}. \tag{13.129.3}$$

Now, fix $g \in \{0,1,...,N\}$. For every $n \in \mathbb{N}$, we have

$$\begin{aligned} \sum_{k=0}^{N} v_{g,k} n^k &= \sum_{\ell=0}^{N} v_{g,\ell} n^{\ell} \qquad \text{(here, we renamed the summation index } k \text{ as } \ell\text{)} \\ &= 0 \qquad \text{(by (13.129.3), applied to } k = g \text{ and } m = n\text{)}. \end{aligned}$$

Hence, Lemma 13.129.1 (applied to $w_k = v_{g,k}$) yields that $v_{g,k} = 0$ for every $k \in \{0,1,...,N\}$.

Now, forget that we fixed g. We thus have shown that $v_{g,k} = 0$ for every $g \in \{0,1,...,N\}$ and $k \in \{0,1,...,N\}$. Renaming the indices g and k as k and ℓ in this statement, we obtain the following: We have $v_{k,\ell} = 0$ for every $k \in \{0,1,...,N\}$ and $\ell \in \{0,1,...,N\}$. In other words, $v_{k,\ell} = 0$ for every $(k,\ell) \in \{0,1,...,N\}^2$. This proves Lemma 13.129.2. □

Now, let us come to the solution of Exercise 5.4.8.

Define $\operatorname{End}_{\mathrm{gr}} A$ as in the solution of Exercise 5.4.6. We can prove (just as in the solution of Exercise 5.4.6) that $(\operatorname{End}_{\mathrm{gr}} A, \star)$ is a $\mathbf{k}$-subalgebra of $(\operatorname{End} A, \star)$. Since $\mathrm{id}_A \in \operatorname{End}_{\mathrm{gr}} A$, we thus have $\mathrm{id}_A^{\star \ell} \in \operatorname{End}_{\mathrm{gr}} A$ for every $\ell \in \mathbb{N}$. In other words,

$$\mathrm{id}_A^{\star \ell} \text{ is a graded } \mathbf{k}\text{-linear map for every } \ell \in \mathbb{N}. \tag{13.129.4}$$

We have $\mathfrak{e}(1_A) = 0$ (as was proven in a footnote in the solution of Exercise 5.4.6). Hence, $\mathfrak{e}\left(\underbrace{A_0}_{=\mathbf{k}\cdot 1_A}\right) = \mathfrak{e}(\mathbf{k} \cdot 1_A) = \mathbf{k} \cdot \underbrace{\mathfrak{e}(1_A)}_{=0} = 0$.

Notice that A is a $\mathbf{k}$-module, hence a $\mathbb{Q}$-module (since $\mathbb{Q}$ is a subring of $\mathbf{k}$), thus a torsionfree abelian group.

(a) For every $\mathbf{k}$-linear map $f : A \to A$ which annihilates A_0, we can define an endomorphism $\exp^\star f$ of A by setting $\exp^\star f = \sum_{\ell \geq 0} \frac{1}{\ell!} f^{\star \ell}$. (This follows from the same argument as the well-definedness of $\log^\star (f + u\epsilon)$. [920]) The usual rules for exponentials and logarithms apply:

- We have $\exp^\star(\log^\star(f + u\epsilon)) = f + u\epsilon$ for every $\mathbf{k}$-linear map $f : A \to A$ which annihilates A_0. [921]
- We have $\log^\star(\exp^\star f) = f$ for every $\mathbf{k}$-linear map $f : A \to A$ which annihilates A_0. [922]
- We have $\exp^\star(f + g) = (\exp^\star f) \star (\exp^\star g)$ for any two $\mathbf{k}$-linear maps $f : A \to A$ and $g : A \to A$ which annihilate A_0 and satisfy $f \star g = g \star f$. [923]

[920] This definition of $\exp^\star f$ is actually a particular case of Definition 1.7.10(d). This can be shown as follows: If $f : A \to A$ is a $\mathbf{k}$-linear map which annihilates A_0, then Proposition 1.7.11(h) (applied to $C = A$) yields $f \in \mathfrak{n}(A,A)$. Therefore, Definition 1.7.10(d) defines a map $\exp^\star f \in \mathfrak{n}(A,A)$. This map is identical to the map $\exp^\star f := \sum_{\ell \geq 0} \frac{1}{\ell!} f^{\star \ell}$ we have just defined, because the map $\exp^\star f$ defined using Definition 1.7.10(d) satisfies

$$\begin{aligned} \exp^\star f &= \sum_{n \geq 0} \frac{1}{n!} f^{\star n} \qquad \left(\text{since } \exp = \sum_{n \geq 0} \frac{1}{n!} T^n\right) \\ &= \sum_{\ell \geq 0} \frac{1}{\ell!} f^{\star \ell}. \end{aligned}$$

[921] Indeed, this follows from Proposition 1.7.18(b) (applied to $C = A$ and $g = f + u\epsilon$), after first observing that $f \in \mathfrak{n}(A,A)$ (by Proposition 1.7.11(h), applied to $C = A$).

[922] Indeed, this follows from Proposition 1.7.18(a) (applied to $C = A$), after first observing that $f \in \mathfrak{n}(A,A)$ (by Proposition 1.7.11(h), applied to $C = A$).

[923] Indeed, this follows from Proposition 1.7.18(c) (applied to $C = A$), after first observing that $f \in \mathfrak{n}(A,A)$ (by Proposition 1.7.11(h), applied to $C = A$) and $g \in \mathfrak{n}(A,A)$ (for similar reasons).

- We have $\exp^\star(nf) = (\exp^\star f)^{\star n}$ for every $n \in \mathbb{N}$ and any $\mathbf{k}$-linear map $f : A \to A$ which annihilates A_0. [924]

The map $\mathfrak{e}$ annihilates A_0 (since $\mathfrak{e}(A_0) = 0$), and thus an endomorphism $\exp^\star \mathfrak{e}$ of A is well-defined. We have $\mathfrak{e} = \log^\star(\mathrm{id}_A)$, so that $\exp^\star \mathfrak{e} = \exp^\star(\log^\star(\mathrm{id}_A)) = \mathrm{id}_A$ (since $\exp^\star(\log^\star(f + u\epsilon)) = f + u\epsilon$ for every $\mathbf{k}$-linear map $f : A \to A$ which annihilates A_0).

Let us recall that any f annihilating A_0 has the property that for each n one has that A_n is annihilated by $f^{\star m}$ for every $m > n$ (we saw this in the proof of Proposition 1.4.24). Applying this to $f = \mathfrak{e}$ (which, as we know, annihilates A_0), and renaming m and n as n and N, we obtain

$$\mathfrak{e}^{\star n}(A_N) = 0 \qquad \text{for every } N \in \mathbb{N} \text{ and every } n \in \mathbb{N} \text{ satisfying } n > N. \tag{13.129.5}$$

Recall that $\exp^\star(nf) = (\exp^\star f)^{\star n}$ for every $n \in \mathbb{N}$ and any $\mathbf{k}$-linear map $f : A \to A$ which annihilates A_0. Applying this to $f = \mathfrak{e}$, we see that every $n \in \mathbb{N}$ satisfies

$$\exp^\star(n\mathfrak{e}) = \Bigg(\underbrace{\exp^\star \mathfrak{e}}_{=\mathrm{id}_A}\Bigg)^{\star n} = \mathrm{id}_A^{\star n}. \tag{13.129.6}$$

Now, let us fix $M \in \mathbb{N}$. Let also N be any integer satisfying $N \geq M$. It is easy to see that

$$\mathrm{id}_A^{\star m}(v) = \sum_{\ell=0}^{N} \frac{1}{\ell!} m^\ell \mathfrak{e}^{\star\ell}(v) \qquad \text{for every } v \in A_M \text{ and every } m \in \mathbb{N}. \tag{13.129.7}$$

[925]

Now, let $v \in A_M$, $n \in \mathbb{N}$ and $m \in \mathbb{N}$ be arbitrary. Since $\mathrm{id}_A^{\star m}$ is a graded map (by (13.129.4), applied to $\ell = m$), we have $\mathrm{id}_A^{\star m}(v) \in A_M$ (since $v \in A_M$). Hence, (13.129.7) (applied to n and $\mathrm{id}_A^{\star m}(v)$ instead of m

[924] Indeed, this follows from Proposition 1.7.18(e) (applied to $C = A$), after first observing that $f \in \mathfrak{n}(A, A)$ (by Proposition 1.7.11(h), applied to $C = A$).

[925] *Proof of (13.129.7):* Let $v \in A_M$ and $m \in \mathbb{N}$. Every integer ℓ satisfying $\ell > M$ satisfies $\mathfrak{e}^{\star\ell}\left(\underbrace{v}_{\in A_M}\right) \in \mathfrak{e}^{\star\ell}(A_M) = 0$ (by (13.129.5), applied to ℓ and M instead of n and N). In other words,

$$\text{every integer } \ell \text{ satisfying } \ell > M \text{ satisfies } \mathfrak{e}^{\star\ell}(v) = 0. \tag{13.129.8}$$

From (13.129.6) (applied to m instead of n), we obtain $\exp^\star(m\mathfrak{e}) = \mathrm{id}_A^{\star m}$, so that

$$\mathrm{id}_A^{\star m} = \exp^\star(m\mathfrak{e}) = \sum_{\ell=0}^{\infty} \frac{1}{\ell!}(m\mathfrak{e})^{\star\ell} = \sum_{\ell=0}^{\infty} \frac{1}{\ell!} m^\ell \mathfrak{e}^{\star\ell}$$

and thus

$$\begin{aligned}\mathrm{id}_A^{\star m}(v) &= \sum_{\ell=0}^{\infty} \frac{1}{\ell!} m^\ell \mathfrak{e}^{\star\ell}(v) = \sum_{\ell=0}^{N} \frac{1}{\ell!} m^\ell \mathfrak{e}^{\star\ell}(v) + \sum_{\ell=N+1}^{\infty} \frac{1}{\ell!} m^\ell \underbrace{\mathfrak{e}^{\star\ell}(v)}_{\substack{=0 \\ (\text{by (13.129.8)}, \\ \text{since } \ell > N \geq M)}} \\ &= \sum_{\ell=0}^{N} \frac{1}{\ell!} m^\ell \mathfrak{e}^{\star\ell}(v) + \underbrace{\sum_{\ell=N+1}^{\infty} \frac{1}{\ell!} m^\ell 0}_{=0} = \sum_{\ell=0}^{N} \frac{1}{\ell!} m^\ell \mathfrak{e}^{\star\ell}(v).\end{aligned}$$

This proves (13.129.7).

and v) yields

$$\begin{aligned}
\operatorname{id}_A^{\star n}\left(\operatorname{id}_A^{\star m}(v)\right) &= \sum_{\ell=0}^{N} \frac{1}{\ell!} n^{\ell} \mathfrak{e}^{\star \ell}\left(\operatorname{id}_A^{\star m}(v)\right) = \sum_{k=0}^{N} \frac{1}{k!} n^{k} \mathfrak{e}^{\star k}\left(\underbrace{\operatorname{id}_A^{\star m}(v)}_{\substack{=\sum_{\ell=0}^{N} \frac{1}{\ell!} m^{\ell} \mathfrak{e}^{\star \ell}(v) \\ \text{(by (13.129.7))}}}\right) \\
&\qquad \left(\text{here, we have renamed the summation index } \ell \text{ as } k\right) \\
&= \sum_{k=0}^{N} \frac{1}{k!} n^{k} \underbrace{\mathfrak{e}^{\star k}\left(\sum_{\ell=0}^{N} \frac{1}{\ell!} m^{\ell} \mathfrak{e}^{\star \ell}(v)\right)}_{\substack{=\sum_{\ell=0}^{N} \frac{1}{\ell!} m^{\ell} \mathfrak{e}^{\star k}\left(\mathfrak{e}^{\star \ell}(v)\right) \\ \text{(since } \mathfrak{e}^{\star k} \text{ is a } \mathbf{k}\text{-linear map)}}} = \sum_{k=0}^{N} \frac{1}{k!} n^{k} \sum_{\ell=0}^{N} \frac{1}{\ell!} m^{\ell} \underbrace{\mathfrak{e}^{\star k}\left(\mathfrak{e}^{\star \ell}(v)\right)}_{=\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)} \\
&= \sum_{k=0}^{N} \frac{1}{k!} n^{k} \sum_{\ell=0}^{N} \frac{1}{\ell!} m^{\ell} \left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v) = \sum_{k=0}^{N} \sum_{\ell=0}^{N} \frac{\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)}{k!\ell!} n^{k} m^{\ell}. \qquad (13.129.9)
\end{aligned}$$

But

$$\begin{aligned}
\operatorname{id}_A^{\star n}\left(\operatorname{id}_A^{\star m}(v)\right) &= \underbrace{\left(\operatorname{id}_A^{\star n} \circ \operatorname{id}_A^{\star m}\right)}_{\substack{=\operatorname{id}_A^{\star (nm)} \\ \text{(by the dual of Exercise 1.5.11(f),} \\ \text{applied to } k=m \text{ and } \ell=n)}}(v) = \operatorname{id}_A^{\star (nm)}(v) \\
&= \sum_{\ell=0}^{N} \frac{1}{\ell!} (nm)^{\ell} \mathfrak{e}^{\star \ell}(v) \qquad \left(\text{by (13.129.7), applied to } nm \text{ instead of } m\right), \qquad (13.129.10)
\end{aligned}$$

Now,

$$\begin{aligned}
&\sum_{k=0}^{N} \sum_{\ell=0}^{N} \left(\frac{\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)}{k!\ell!} - \frac{\delta_{k,\ell} \mathfrak{e}^{\star k}(v)}{k!}\right) n^{k} m^{\ell} = \underbrace{\sum_{k=0}^{N} \sum_{\ell=0}^{N} \frac{\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)}{k!\ell!} n^{k} m^{\ell}}_{\substack{=\operatorname{id}_A^{\star n}\left(\operatorname{id}_A^{\star m}(v)\right) \\ \text{(by (13.129.9))}}} - \underbrace{\sum_{k=0}^{N} \sum_{\ell=0}^{N} \frac{\delta_{k,\ell} \mathfrak{e}^{\star k}(v)}{k!} n^{k} m^{\ell}}_{\substack{=\sum_{\ell=0}^{N} \frac{\mathfrak{e}^{\star \ell}(v)}{\ell!} n^{\ell} m^{\ell} \\ =\sum_{\ell=0}^{N} \frac{1}{\ell!} (nm)^{\ell} \mathfrak{e}^{\star \ell}(v) \\ =\operatorname{id}_A^{\star n}\left(\operatorname{id}_A^{\star m}(v)\right) \\ \text{(by (13.129.10))}}} \\
&= \operatorname{id}_A^{\star n}\left(\operatorname{id}_A^{\star m}(v)\right) - \operatorname{id}_A^{\star n}\left(\operatorname{id}_A^{\star m}(v)\right) = 0.
\end{aligned}$$

Now, let us forget that we fixed n and m. We thus have proven that

$$\sum_{k=0}^{N} \sum_{\ell=0}^{N} \left(\frac{\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)}{k!\ell!} - \frac{\delta_{k,\ell} \mathfrak{e}^{\star k}(v)}{k!}\right) n^{k} m^{\ell} = 0$$

for all $n \in \mathbb{N}$ and $m \in \mathbb{N}$. Hence, we can apply Lemma 13.129.2 to $V = A$ and $v_{k,\ell} = \frac{\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)}{k!\ell!} - \frac{\delta_{k,\ell} \mathfrak{e}^{\star k}(v)}{k!}$ (because A is a torsionfree abelian group). As a result, we obtain $\frac{\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)}{k!\ell!} - \frac{\delta_{k,\ell} \mathfrak{e}^{\star k}(v)}{k!} = 0$ for every $(k, \ell) \in \{0, 1, ..., N\}^2$. In other words,

$$\frac{\left(\mathfrak{e}^{\star k} \circ \mathfrak{e}^{\star \ell}\right)(v)}{k!\ell!} = \frac{\delta_{k,\ell} \mathfrak{e}^{\star k}(v)}{k!} \qquad \text{for every } (k, \ell) \in \{0, 1, ..., N\}^2. \qquad (13.129.11)$$

Now, forget that we fixed v, M and N. We thus have proven that every $M \in \mathbb{N}$, every integer N satisfying $N \geq M$, and every $v \in A_M$ satisfy (13.129.11).

Now, let us fix two elements $n \in \mathbb{N}$ and $m \in \mathbb{N}$. In order to finish the solution of Exercise 5.4.8(a), it remains to show that $\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star m} = n!\delta_{n,m}\mathfrak{e}^{\star n}$. In order to show this, it is clearly enough to prove that $\left(\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star m}\right)(v) = n!\delta_{n,m}\mathfrak{e}^{\star n}(v)$ for every $v \in A$. So let us fix some $v \in A$, and let us show that $\left(\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star m}\right)(v) = n!\delta_{n,m}\mathfrak{e}^{\star n}(v)$.

Since both sides of the identity $\left(\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star m}\right)(v) = n!\delta_{n,m}\mathfrak{e}^{\star n}(v)$ are $\mathbf{k}$-linear in v, we can WLOG assume that v is a homogeneous element of A (because every element of A is a $\mathbf{k}$-linear combination of homogeneous elements). Assume this. Thus, $v \in A_M$ for some $M \in \mathbb{N}$. Consider this M. Choose some $N \in \mathbb{N}$ satisfying $N \geq M$, $N \geq n$ and $N \geq m$. (Such an N clearly exists.) Then, $N \geq M$ and $(n,m) \in \{0,1,...,N\}^2$, and therefore we can apply (13.129.11) to $k = n$ and $\ell = m$. As a result, we obtain $\dfrac{\left(\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star m}\right)(v)}{n!m!} = \dfrac{\delta_{n,m}\mathfrak{e}^{\star n}(v)}{n!}$. Multiplying this identity with $n!m!$, we obtain

$$\left(\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star m}\right)(v) = \underbrace{m!\delta_{n,m}}_{\substack{=n!\delta_{n,m} \\ \text{(indeed, this is clear if } n=m\text{,} \\ \text{and otherwise follows from } \delta_{n,m}=0\text{)}}} \mathfrak{e}^{\star n}(v) = n!\delta_{n,m}\mathfrak{e}^{\star n}(v).$$

So we have proven $\left(\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star m}\right)(v) = n!\delta_{n,m}\mathfrak{e}^{\star n}(v)$. As we have seen, this completes the solution of Exercise 5.4.8(a).

(b) Let $n \in \mathbb{N}$ and $m \in \mathbb{N}$. From (13.129.6) (applied to m instead of n), we obtain $\exp^{\star}(m\mathfrak{e}) = \operatorname{id}_A^{\star m}$, so that

$$\operatorname{id}_A^{\star m} = \exp^{\star}(m\mathfrak{e}) = \sum_{\ell=0}^{\infty} \frac{1}{\ell!}(m\mathfrak{e})^{\star \ell} = \sum_{\ell=0}^{\infty} \frac{1}{\ell!} m^{\ell} \mathfrak{e}^{\star \ell}.$$

Thus,

$$\begin{aligned} \mathfrak{e}^{\star n} \circ \underbrace{\operatorname{id}_A^{\star m}}_{=\sum_{\ell=0}^{\infty} \frac{1}{\ell!} m^{\ell} \mathfrak{e}^{\star \ell}} &= \mathfrak{e}^{\star n} \circ \left(\sum_{\ell=0}^{\infty} \frac{1}{\ell!} m^{\ell} \mathfrak{e}^{\star \ell} \right) = \underbrace{\sum_{\ell=0}^{\infty}}_{=\sum_{\ell \in \mathbb{N}}} \frac{1}{\ell!} m^{\ell} \underbrace{\mathfrak{e}^{\star n} \circ \mathfrak{e}^{\star \ell}}_{\substack{=n!\delta_{n,\ell}\mathfrak{e}^{\star n} \\ \text{(by Exercise 5.4.8(a),} \\ \text{applied to } \ell \text{ instead of } m\text{)}}} \\ &= \sum_{\ell \in \mathbb{N}} \frac{1}{\ell!} m^{\ell} n! \delta_{n,\ell} \mathfrak{e}^{\star n} = \frac{1}{n!} m^n n! \mathfrak{e}^{\star n} = m^n \mathfrak{e}^{\star n} \end{aligned}$$

and similarly $\operatorname{id}_A^{\star m} \circ \mathfrak{e}^{\star n} = m^n \mathfrak{e}^{\star n}$. This solves Exercise 5.4.8(b).

13.130. **Solution to Exercise 5.4.12.** *Solution to Exercise 5.4.12.* (a) This is proven by induction over i. The induction step relies on the observation that $R_{(1^i,n-i)} + R_{(1^{i-1},n-i+1)} = R_{(1^i)}H_{n-i}$ (where $R_{(1^{-1},n+1)}$ is to be understood to mean 0 in the $i = 0$ case). Let us prove this observation. We assume WLOG that $i > 0$ (the proof in the $i = 0$ case is analogous but simpler). The equality (5.4.9) yields $H_{n-i} = R_{(n-i)}$ (since only $(n-i)$ coarsens $(n-i)$), so that

$$\begin{aligned} R_{(1^i)}H_{n-i} &= R_{(1^i)}R_{(n-i)} = R_{(1^i)\cdot(n-i)} + R_{(1^i)\odot(n-i)} \qquad \text{(by (5.4.11))} \\ &= R_{(1^i,n-i)} + R_{(1^{i-1},n-i+1)}, \end{aligned}$$

qed.

(b) Part (a) yields

$$\begin{aligned} (-1)^i R_{(1^i,n-i)} &= (-1)^i \sum_{j=0}^{i} (-1)^{i-j} R_{(1^j)} H_{n-j} = \sum_{j=0}^{i} \underbrace{(-1)^j R_{(1^j)}}_{\substack{=S\left(R_{(j)}\right) \\ \text{(by (5.4.12), since } \omega((j))=\left(1^j\right)\text{)}}} H_{n-j} \\ &= \sum_{j=0}^{i} S\left(\underbrace{R_{(j)}}_{\substack{=H_j \\ \text{(by (5.4.9))}}} \right) H_{n-j} = \sum_{j=0}^{i} S(H_j) H_{n-j}. \end{aligned}$$

This proves (b).

(c) We have

$$\begin{aligned}
\Psi_n &= \sum_{i=0}^{n-1} \underbrace{(-1)^i R_{(1^i,n-i)}}_{\substack{=\sum_{j=0}^{i} S(H_j) H_{n-j} \\ \text{(by part (b))}}} = \sum_{i=0}^{n-1} \sum_{j=0}^{i} S(H_j) H_{n-j} = \sum_{j=0}^{n} \sum_{i=j}^{n-1} S(H_j) H_{n-j} \\
&= \sum_{j=0}^{n} (n-j) S(H_j) H_{n-j} = \sum_{j=0}^{n} S(H_j) \underbrace{(n-j) H_{n-j}}_{=\deg(H_{n-j}) H_{n-j} = E(H_{n-j})} \\
&= \sum_{j=0}^{n} S(H_j) E(H_{n-j}) = \sum_{(H_n)} S((H_n)_1) E((H_n)_2) \\
&\qquad \left(\text{using Sweedler notation, since } \Delta(H_n) = \sum_{j=0}^{n} H_j \otimes H_{n-j} \right) \\
&= (S \star E)(H_n),
\end{aligned}$$

and thus Ψ_n is primitive (by Exercise 1.5.14 (a)). (That said, there are other ways to prove the primitivity of Ψ_n.)

(d) Let $n \in \mathbb{N}$. Then,

$$\begin{aligned}
\sum_{k=0}^{n-1} H_k \underbrace{\Psi_{n-k}}_{\substack{=(S\star E)(H_{n-k}) \\ \text{(by part (c))}}} &= \sum_{k=0}^{n-1} H_k (S \star E)(H_{n-k}) = \sum_{k=0}^{n} H_k (S \star E)(H_{n-k}) \\
&\qquad \text{(we added a } k = n \text{ term, which does not matter since it vanishes)} \\
&= \sum_{(H_n)} (H_n)_1 (S \star E)((H_n)_2) \\
&\qquad \left(\text{using Sweedler notation, since } \Delta(H_n) = \sum_{k=0}^{n} H_k \otimes H_{n-k} \right) \\
&= \left(\underbrace{\operatorname{id} \star S}_{=u\epsilon} \star E \right)(H_n) = \underbrace{(u\epsilon \star E)}_{=E}(H_n) = E(H_n) = nH_n,
\end{aligned}$$

qed.

(e) Comparing coefficients reduces this to part (d).

(f) The ring homomorphism $\pi : \operatorname{NSym} \to \Lambda$ induces a ring homomorphism $\operatorname{NSym}[[t]] \to \Lambda[[t]]$. Applying this latter homomorphism to the equality $\dfrac{d}{dt}\widetilde{H}(t) = \widetilde{H}(t) \cdot \psi(t)$ of part (e), we obtain $\dfrac{d}{dt} H(t) = H(t) \cdot \overline{\psi}(t)$, where $H(t)$ is defined as in (2.4.1), whereas $\overline{\psi}(t) \in \Lambda[[t]]$ is defined by

$$\overline{\psi}(t) = \sum_{n \geq 1} \pi(\Psi_n) t^{n-1}.$$

Hence,

$$\begin{aligned}
\overline{\psi}(t) &= \frac{\frac{d}{dt} H(t)}{H(t)} = \frac{H'(t)}{H(t)} = \sum_{m \geq 0} p_{m+1} t^m \qquad \text{(by (2.5.13))} \\
&= \sum_{n \geq 1} p_n t^{n-1}.
\end{aligned}$$

Comparing coefficients in this equality yields $\pi(\Psi_n) = p_n$ for every positive integer n. This solves part (f).

Remark: Another way to solve Exercise 5.4.12(f) proceeds as follows: We know that Ψ_n is a primitive homogeneous element of NSym of degree n (by Exercise 5.4.12(c)). Thus, $\pi(\Psi_n)$ is a primitive homogeneous element of Λ of degree n (since π is a graded homomorphism of Hopf algebras). But Exercise 3.1.9 shows that all such elements are scalar multiples of p_n. Thus, $\pi(\Psi_n)$ is a scalar multiple of p_n. Finding the scalar is easy (e.g., it can be obtained by specializing at (1)).

(g) Let n be a positive integer. We know that $\Psi_n = \sum_{i=0}^{n-1} (-1)^i R_{(1^i, n-i)}$. Applying π to this equation, we obtain $\pi(\Psi_n) = \sum_{i=0}^{n-1} (-1)^i \pi\left(R_{(1^i,n-i)}\right)$. Since $\pi(\Psi_n) = p_n$ (by part (f)), this rewrites as $p_n = \sum_{i=0}^{n-1} (-1)^i \pi\left(R_{(1^i,n-i)}\right)$. But we need to show that $p_n = \sum_{i=0}^{n-1} (-1)^i s_{(n-i,1^i)}$. Hence, it is enough to prove that every $i \in \{0, 1, \ldots, n-1\}$ satisfies $\pi\left(R_{(1^i,n-i)}\right) = s_{(n-i,1^i)}$.

So let $i \in \{0, 1, \ldots, n-1\}$ be arbitrary. Theorem 5.4.10(b) (applied to $\alpha = \left(1^i, n-i\right)$) shows that $\pi\left(R_{(1^i,n-i)}\right) = s_\alpha$, where α is the ribbon diagram of the composition $\left(1^i, n-i\right)$. But since the ribbon diagram of the composition $\left(1^i, n-i\right)$ is the Ferrers diagram for the partition $\left(n-i, 1^i\right)$ (because its row lengths are $\underbrace{1, 1, \ldots, 1}_{i \text{ times}}, n-i$ going from bottom to top, with an overlap of 1 between every two adjacent rows), we have $s_\alpha = s_{(n-i,1^i)}$. Hence, $\pi\left(R_{(1^i,n-i)}\right) = s_\alpha = s_{(n-i,1^i)}$. As we have seen, this completes the solution of part (g).

(h) We will prove (5.4.13) by strong induction over n. So let N be an arbitrary positive integer, and let us assume that (5.4.13) has been proven for every $n < N$. We now need to prove (5.4.13) for $n = N$.

We notice that the family $(H_\alpha)_{\alpha \in \mathrm{NSym}}$ is multiplicative, in the sense that any two compositions β and γ satisfy $H_{\beta \cdot \gamma} = H_\beta \cdot H_\gamma$ (where, as we recall, $\beta \cdot \gamma$ denotes the concatenation of the compositions β and γ). This follows from the definition of the H_α.

We have $N > 0$. Hence, every $\alpha \in \mathrm{Comp}_N$ can be written uniquely in the form $\alpha = (q) \cdot \beta$ for some $q \in \{1, 2, ..., N\}$ and some $\beta \in \mathrm{Comp}_{N-q}$ (indeed, the q is just the first entry of the composition α, and β is the composition obtained by erasing this first entry). Hence,

$$\begin{aligned}
&\sum_{\alpha \in \mathrm{Comp}_N} (-1)^{\ell(\alpha)-1} \operatorname{lp}(\alpha) H_\alpha \\
&= \underbrace{\sum_{\substack{q \in \{1,2,\ldots,N\};\\ \beta \in \mathrm{Comp}_{N-q}}}}_{=\sum_{q=1}^{N} \sum_{\beta \in \mathrm{Comp}_{N-q}}} \underbrace{(-1)^{\ell((q)\cdot\beta)-1}}_{\substack{=(-1)^{\ell(\beta)}\\ \text{(since it is easy to see that}\\ \ell((q)\cdot\beta)-1=\ell(\beta))}} \operatorname{lp}((q)\cdot\beta) \underbrace{H_{(q)\cdot\beta}}_{\substack{=H_{(q)}\cdot H_\beta\\ \text{(since the family}\\ (H_\alpha)_{\alpha\in\mathrm{NSym}} \text{ is}\\ \text{multiplicative)}}} \\
&= \sum_{q=1}^{N} \sum_{\beta \in \mathrm{Comp}_{N-q}} (-1)^{\ell(\beta)} \operatorname{lp}((q)\cdot\beta) \cdot H_{(q)} \cdot H_\beta \\
&= \sum_{q=1}^{N-1} \sum_{\beta \in \mathrm{Comp}_{N-q}} (-1)^{\ell(\beta)} \underbrace{\operatorname{lp}((q)\cdot\beta)}_{\substack{=\operatorname{lp}(\beta)\\ \text{(since } \beta \text{ is}\\ \text{nonempty)}}} \cdot H_{(q)} \cdot H_\beta + \underbrace{\sum_{\beta \in \mathrm{Comp}_{N-N}} (-1)^{\ell(\beta)} \operatorname{lp}((N)\cdot\beta) \cdot H_{(N)} \cdot H_\beta}_{\substack{=(-1)^{\ell(\varnothing)} \operatorname{lp}((N)\cdot\varnothing)\cdot H_{(N)}\cdot H_\varnothing\\ \text{(since the only element of } \mathrm{Comp}_{N-N}\\ \text{is the empty composition } \varnothing)}} \\
&= \sum_{q=1}^{N-1} \underbrace{\sum_{\beta \in \mathrm{Comp}_{N-q}} (-1)^{\ell(\beta)} \operatorname{lp}(\beta) \cdot H_{(q)} \cdot H_\beta}_{=H_{(q)}\cdot\left(\sum_{\beta\in\mathrm{Comp}_{N-q}} (-1)^{\ell(\beta)} \operatorname{lp}(\beta) H_\beta\right)} + \underbrace{(-1)^{\ell(\varnothing)}}_{=1} \underbrace{\operatorname{lp}((N)\cdot\varnothing)}_{=\operatorname{lp}((N))=N} \cdot \underbrace{H_{(N)}}_{=H_N} \cdot \underbrace{H_\varnothing}_{=1} \\
&= \sum_{q=1}^{N-1} H_{(q)} \cdot \left(\sum_{\beta \in \mathrm{Comp}_{N-q}} (-1)^{\ell(\beta)} \operatorname{lp}(\beta) H_\beta \right) + N H_N. \qquad (13.130.1)
\end{aligned}$$

However, for every $q \in \{1, 2, ..., N-1\}$, we can apply (5.4.13) to $n = N - q$ (because $N - q < N$, and because (5.4.13) has been proven for every $n < N$). Thus, for every $q \in \{1, 2, ..., N-1\}$, we obtain

$$\Psi_{N-q} = \sum_{\alpha \in \operatorname{Comp}_{N-q}} \underbrace{(-1)^{\ell(\alpha)-1}}_{=-(-1)^{\ell(\alpha)}} \operatorname{lp}(\alpha) H_\alpha = - \sum_{\alpha \in \operatorname{Comp}_{N-q}} (-1)^{\ell(\alpha)} \operatorname{lp}(\alpha) H_\alpha = - \sum_{\beta \in \operatorname{Comp}_{N-q}} (-1)^{\ell(\beta)} \operatorname{lp}(\beta) H_\beta$$

(here, we renamed the summation index α as β), so that

$$-\Psi_{N-q} = \sum_{\beta \in \operatorname{Comp}_{N-q}} (-1)^{\ell(\beta)} \operatorname{lp}(\beta) H_\beta. \tag{13.130.2}$$

Thus, (13.130.1) becomes

$$\begin{aligned} \sum_{\alpha \in \operatorname{Comp}_N} (-1)^{\ell(\alpha)-1} \operatorname{lp}(\alpha) H_\alpha &= \sum_{q=1}^{N-1} \underbrace{H_{(q)}}_{=H_q} \cdot \underbrace{\left(\sum_{\beta \in \operatorname{Comp}_{N-q}} (-1)^{\ell(\beta)} \operatorname{lp}(\beta) H_\beta \right)}_{\substack{=-\Psi_{N-q} \\ \text{(this follows from (13.130.2))}}} + NH_N \\ &= \sum_{q=1}^{N-1} H_q \cdot (-\Psi_{N-q}) + NH_N = - \sum_{q=1}^{N-1} H_q \Psi_{N-q} + NH_N. \qquad (13.130.3) \end{aligned}$$

However, Exercise 5.4.12(d) (applied to $n = N$) yields $\sum_{k=0}^{N-1} H_k \Psi_{N-k} = NH_N$, so that

$$NH_N = \sum_{k=0}^{N-1} H_k \Psi_{N-k} = \sum_{q=0}^{N-1} H_q \Psi_{N-q} = \underbrace{H_0}_{=1} \underbrace{\Psi_{N-0}}_{=\Psi_N} + \sum_{q=1}^{N-1} H_q \Psi_{N-q} = \Psi_N + \sum_{q=1}^{N-1} H_q \Psi_{N-q}.$$

Now, (13.130.3) becomes

$$\begin{aligned} &\sum_{\alpha \in \operatorname{Comp}_N} (-1)^{\ell(\alpha)-1} \operatorname{lp}(\alpha) H_\alpha \\ &= - \sum_{q=1}^{N-1} H_q \Psi_{N-q} + \underbrace{NH_N}_{=\Psi_N + \sum_{q=1}^{N-1} H_q \Psi_{N-q}} = - \sum_{q=1}^{N-1} H_q \Psi_{N-q} + \Psi_N + \sum_{q=1}^{N-1} H_q \Psi_{N-q} = \Psi_N. \end{aligned}$$

In other words, $\Psi_N = \sum_{\alpha \in \operatorname{Comp}_N} (-1)^{\ell(\alpha)-1} \operatorname{lp}(\alpha) H_\alpha$. Thus, (5.4.13) is proven for $n = N$. This completes the induction step, and therefore the proof of (5.4.13) is complete. That is, part (h) of the exercise is solved.

(i) First of all, for every positive integer n, the element Ψ_n of NSym is homogeneous of degree n (this follows from the definition of Ψ_n or, alternatively, from Exercise 5.4.12(h)). Hence, for every composition α, the element Ψ_α of NSym is homogeneous of degree $|\alpha|$.

We notice that the family $(\Psi_\alpha)_{\alpha \in \mathrm{NSym}}$ is multiplicative, in the sense that any two compositions β and γ satisfy $\Psi_{\beta \cdot \gamma} = \Psi_\beta \cdot \Psi_\gamma$ (where, as we recall, $\beta \cdot \gamma$ denotes the concatenation of the compositions β and γ). This follows from the definition of the Ψ_α.

Let us now prove (5.4.14). Indeed, we will show (5.4.14) by strong induction over n. So let $N \in \mathbb{N}$ be arbitrary, and let us assume that (5.4.14) has been proven for every $n < N$. We now need to prove (5.4.14) for $n = N$.

If $N = 0$, then (5.4.14) obviously holds for $n = N$ (because both sides of (5.4.14) are 1_{NSym} in this case). We thus WLOG assume that $N \neq 0$. Thus, every $\alpha \in \operatorname{Comp}_N$ can be written uniquely in the form $\alpha = \beta \cdot (q)$ for some $q \in \{1, 2, ..., N\}$ and some $\beta \in \operatorname{Comp}_{N-q}$ (indeed, the q is just the last entry of the composition α, and β is the composition obtained by erasing this last entry). Hence,

$$\begin{aligned}
\sum_{\alpha\in\operatorname{Comp}_N} \frac{1}{\pi_u(\alpha)}\Psi_\alpha &= \underbrace{\sum_{\substack{q\in\{1,2,...,N\};\\ \beta\in\operatorname{Comp}_{N-q}}}}_{=\sum_{q=1}^{N}\sum_{\beta\in\operatorname{Comp}_{N-q}}} \underbrace{\frac{1}{\pi_u(\beta\cdot(q))}}_{\substack{=\frac{1}{\pi_u(\beta)\cdot N}\\ \text{(since it is easy to see that}\\ \pi_u(\beta\cdot(q))=\pi_u(\beta)\cdot N)}} \underbrace{\Psi_{\beta\cdot(q)}}_{\substack{=\Psi_\beta\cdot\Psi_{(q)}\\ \text{(since the family}\\ (\Psi_\alpha)_{\alpha\in\operatorname{NSym}}\text{ is}\\ \text{multiplicative)}}} \\
&= \sum_{q=1}^{N}\sum_{\beta\in\operatorname{Comp}_{N-q}} \underbrace{\frac{1}{\pi_u(\beta)\cdot N}}_{=\frac{1}{N}\cdot\frac{1}{\pi_u(\beta)}} \Psi_\beta\cdot\underbrace{\Psi_{(q)}}_{=\Psi_q} \\
&= \sum_{q=1}^{N}\sum_{\beta\in\operatorname{Comp}_{N-q}} \frac{1}{N}\cdot\frac{1}{\pi_u(\beta)}\Psi_\beta\cdot\Psi_q
\end{aligned}$$

$$= \frac{1}{N}\sum_{q=1}^{N}\left(\sum_{\beta\in\operatorname{Comp}_{N-q}}\frac{1}{\pi_u(\beta)}\Psi_\beta\right)\cdot\Psi_q. \tag{13.130.4}$$

However, for every $q\in\{1,2,...,N\}$, we can apply (5.4.14) to $n=N-q$ (because $N-q<N$, and because (5.4.14) has been proven for every $n<N$). Thus, for every $q\in\{1,2,...,N\}$, we obtain

$$H_{N-q} = \sum_{\alpha\in\operatorname{Comp}_{N-q}}\frac{1}{\pi_u(\alpha)}\Psi_\alpha = \sum_{\beta\in\operatorname{Comp}_{N-q}}\frac{1}{\pi_u(\beta)}\Psi_\beta \tag{13.130.5}$$

(here, we renamed the summation index α as β). Thus, (13.130.4) becomes

$$\begin{aligned}
\sum_{\alpha\in\operatorname{Comp}_N}\frac{1}{\pi_u(\alpha)}\Psi_\alpha &= \frac{1}{N}\sum_{q=1}^{N}\underbrace{\left(\sum_{\beta\in\operatorname{Comp}_{N-q}}\frac{1}{\pi_u(\beta)}\Psi_\beta\right)}_{\substack{=H_{N-q}\\ \text{(by (13.130.5))}}}\cdot\Psi_q \\
&= \frac{1}{N}\sum_{q=1}^{N}H_{N-q}\Psi_q = \frac{1}{N}\underbrace{\sum_{k=0}^{N-1}H_k\Psi_{N-k}}_{\substack{=NH_N\\ \text{(by Exercise 5.4.12(d),}\\ \text{applied to }n=N)}} \\
&\qquad \text{(here, we substituted } N-k \text{ for } q \text{ in the sum)} \\
&= \frac{1}{N}NH_N = H_N.
\end{aligned}$$

In other words, $H_N = \sum_{\alpha\in\operatorname{Comp}_N}\frac{1}{\pi_u(\alpha)}\Psi_\alpha$. Thus, (5.4.14) is proven for $n=N$. This completes the induction step, and therefore the proof of (5.4.14) is complete.

We now need to prove that $(\Psi_\alpha)_{\alpha\in\operatorname{Comp}_n}$ is a $\mathbf{k}$-basis of NSym_n for every $n\in\mathbb{N}$. It is clear that $(\Psi_\alpha)_{\alpha\in\operatorname{Comp}_n}$ is a family of elements of NSym_n (because for every composition α, the element Ψ_α of NSym is homogeneous of degree $|\alpha|$).

Let $\mathfrak{A}$ be the $\mathbf{k}$-subalgebra of NSym generated by the elements Ψ_1, Ψ_2, Ψ_3, ... Then, $\mathfrak{A}$ contains Ψ_α for every composition α (by the definition of Ψ_α). Therefore, $\mathfrak{A}$ contains H_n for every $n\geq 1$ (by (5.4.14)). Consequently, $\mathfrak{A}=\operatorname{NSym}$ (because NSym is generated as a $\mathbf{k}$-algebra by H_1, H_2, H_3, ...). In other words, the $\mathbf{k}$-algebra NSym is generated by the elements Ψ_1, Ψ_2, Ψ_3, ... (since we defined $\mathfrak{A}$ as the $\mathbf{k}$-subalgebra of NSym generated by the elements Ψ_1, Ψ_2, Ψ_3, ...). In other words, the $\mathbf{k}$-module NSym is spanned by all possible products of the elements Ψ_1, Ψ_2, Ψ_3, ... In other words, the $\mathbf{k}$-module NSym is spanned by the elements Ψ_α with $\alpha\in\operatorname{Comp}$ (because the elements Ψ_α with $\alpha\in\operatorname{Comp}$ are precisely all possible products of the elements Ψ_1, Ψ_2, Ψ_3, ...). In yet other words, the family $(\Psi_\alpha)_{\alpha\in\operatorname{Comp}}$ spans the $\mathbf{k}$-module NSym.

Now, fix $n \in \mathbb{N}$. Every element of NSym_n can be written as a $\mathbf{k}$-linear combination of the elements Ψ_α with $\alpha \in \mathrm{Comp}$ (since the family $(\Psi_\alpha)_{\alpha\in\mathrm{Comp}}$ spans the $\mathbf{k}$-module NSym). In this $\mathbf{k}$-linear combination, we can remove all terms Ψ_α with $\alpha \notin \mathrm{Comp}_n$ without changing its value (by gradedness, because Ψ_α is homogeneous of degree $|\alpha|$), and so we conclude that every element of NSym_n can be written as a $\mathbf{k}$-linear combination of the elements Ψ_α with $\alpha \in \mathrm{Comp}_n$. In other words, the family $(\Psi_\alpha)_{\alpha\in\mathrm{Comp}_n}$ spans the $\mathbf{k}$-module NSym_n.

Now, we can apply Exercise 2.5.18(b) to $A = \mathrm{NSym}_n$, $I = \mathrm{Comp}_n$, $(\gamma_i)_{i\in I} = (H_\alpha)_{\alpha\in\mathrm{Comp}_n}$ and $(\beta_i)_{i\in I} = (\Psi_\alpha)_{\alpha\in\mathrm{Comp}_n}$ (since we know that $(H_\alpha)_{\alpha\in\mathrm{Comp}_n}$ is a $\mathbf{k}$-basis of NSym_n, whereas $(\Psi_\alpha)_{\alpha\in\mathrm{Comp}_n}$ spans the $\mathbf{k}$-module NSym_n). We conclude that $(\Psi_\alpha)_{\alpha\in\mathrm{Comp}_n}$ is a $\mathbf{k}$-basis of NSym_n. This completes the solution of part (i).

(j) For every composition α, define an element $\mathfrak{b}_\alpha$ of $T(V)$ by $\mathfrak{b}_\alpha = \mathfrak{b}_{\alpha_1}\mathfrak{b}_{\alpha_2}\cdots\mathfrak{b}_{\alpha_\ell}$, where α is written in the form $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ with $\ell = \ell(\alpha)$. Then, $(\mathfrak{b}_\alpha)_{\alpha\in\mathrm{Comp}}$ is a $\mathbf{k}$-module basis of $T(V)$ (by the basic properties of tensor algebras, since $(\mathfrak{b}_n)_{n\in\{1,2,3,\ldots\}}$ is a $\mathbf{k}$-module basis of V). Notice that the family $(\mathfrak{b}_n)_{n\in\{1,2,3,\ldots\}}$ generates the $\mathbf{k}$-algebra $T(V)$ (since it is a basis of V).

For every composition α, define an element Ψ_α of NSym as in Exercise 5.4.12(i). We know from Exercise 5.4.12(i) that $(\Psi_\alpha)_{\alpha\in\mathrm{Comp}_n}$ is a $\mathbf{k}$-basis of NSym_n for every $n \in \mathbb{N}$. Hence, $(\Psi_\alpha)_{\alpha\in\mathrm{Comp}}$ is a $\mathbf{k}$-basis of NSym.

Every $\alpha \in \mathrm{Comp}$ satisfies $F(\mathfrak{b}_\alpha) = \Psi_\alpha$ [926]. The map F thus maps the basis $(\mathfrak{b}_\alpha)_{\alpha\in\mathrm{Comp}}$ of the $\mathbf{k}$-module $T(V)$ to the basis $(\Psi_\alpha)_{\alpha\in\mathrm{Comp}}$ of the $\mathbf{k}$-module NSym. Hence, F is a $\mathbf{k}$-module isomorphism (since any $\mathbf{k}$-linear map mapping a basis to a basis is a $\mathbf{k}$-module isomorphism).

Next, we are going to show the equality $\Delta_{\mathrm{NSym}} \circ F = (F \otimes F) \circ \Delta_{T(V)}$. Indeed, this is an equality between $\mathbf{k}$-algebra homomorphisms, and thus needs only to be verified on a generating set of the $\mathbf{k}$-algebra $T(V)$. Picking $(\mathfrak{b}_n)_{n\in\{1,2,3,\ldots\}}$ as this generating set, we thus only need to check that $(\Delta_{\mathrm{NSym}} \circ F)(\mathfrak{b}_n) = \left((F \otimes F) \circ \Delta_{T(V)}\right)(\mathfrak{b}_n)$ for every positive integer n. This is straightforward: If n is any positive integer, then comparing the equalities

$$(\Delta_{\mathrm{NSym}} \circ F)(\mathfrak{b}_n) = \Delta_{\mathrm{NSym}}\left(\underbrace{F(\mathfrak{b}_n)}_{\substack{=f(\mathfrak{b}_n)\\ \text{(since } F \text{ is induced by } f\text{)}}}\right) = \Delta_{\mathrm{NSym}}\left(\underbrace{f(\mathfrak{b}_n)}_{\substack{=\Psi_n\\ \text{(by the definition of } f\text{)}}}\right) = \Delta_{\mathrm{NSym}}(\Psi_n)$$
$$= 1 \otimes \Psi_n + \Psi_n \otimes 1 \qquad \text{(since Exercise 5.4.12(c) shows that } \Psi_n \text{ is primitive)}$$

and

$$\left((F \otimes F) \circ \Delta_{T(V)}\right)(\mathfrak{b}_n) = (F \otimes F)\left(\underbrace{\Delta_{T(V)}(\mathfrak{b}_n)}_{\substack{=1\otimes\mathfrak{b}_n+\mathfrak{b}_n\otimes 1\\ \text{(by the definition of the}\\ \text{comultiplication on } T(V)\text{)}}}\right) = (F \otimes F)(1 \otimes \mathfrak{b}_n + \mathfrak{b}_n \otimes 1)$$
$$= \underbrace{F(1)}_{\substack{=1\\ \text{(since } F \text{ is a } \mathbf{k}\text{-algebra}\\ \text{homomorphism)}}} \otimes \underbrace{F(\mathfrak{b}_n)}_{\substack{=f(\mathfrak{b}_n)\\ \text{(since } F \text{ is induced by } f\text{)}}} + \underbrace{F(\mathfrak{b}_n)}_{\substack{=f(\mathfrak{b}_n)\\ \text{(since } F \text{ is induced by } f\text{)}}} \otimes \underbrace{F(1)}_{\substack{=1\\ \text{(since } F \text{ is a } \mathbf{k}\text{-algebra}\\ \text{homomorphism)}}}$$
$$= 1 \otimes \underbrace{f(\mathfrak{b}_n)}_{\substack{=\Psi_n\\ \text{(by the definition of } f\text{)}}} + \underbrace{f(\mathfrak{b}_n)}_{\substack{=\Psi_n\\ \text{(by the definition of } f\text{)}}} \otimes 1 = 1 \otimes \Psi_n + \Psi_n \otimes 1$$

[926] *Proof.* Let $\alpha \in \mathrm{Comp}$. Write α in the form $\alpha = (\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ with $\ell = \ell(\alpha)$. Then, $\mathfrak{b}_\alpha = \mathfrak{b}_{\alpha_1}\mathfrak{b}_{\alpha_2}\cdots\mathfrak{b}_{\alpha_\ell}$, so that

$$F(\mathfrak{b}_\alpha) = F(\mathfrak{b}_{\alpha_1}\mathfrak{b}_{\alpha_2}\cdots\mathfrak{b}_{\alpha_\ell}) = \underbrace{f(\mathfrak{b}_{\alpha_1})}_{\substack{=\Psi_{\alpha_1}\\ \text{(by the definition of } f\text{)}}} \underbrace{f(\mathfrak{b}_{\alpha_2})}_{\substack{=\Psi_{\alpha_2}\\ \text{(by the definition of } f\text{)}}} \cdots \underbrace{f(\mathfrak{b}_{\alpha_\ell})}_{\substack{=\Psi_{\alpha_\ell}\\ \text{(by the definition of } f\text{)}}}$$
$$\text{(by the definition of } F\text{)}$$
$$= \Psi_{\alpha_1}\Psi_{\alpha_2}\cdots\Psi_{\alpha_\ell} = \Psi_\alpha \qquad \text{(since } \Psi_\alpha \text{ was defined to be } \Psi_{\alpha_1}\Psi_{\alpha_2}\cdots\Psi_{\alpha_\ell}\text{)},$$

qed.

yields $\left(\Delta_{\mathrm{NSym}} \circ F\right)(\mathfrak{b}_n) = \left((F \otimes F) \circ \Delta_{T(V)}\right)(\mathfrak{b}_n)$. We thus have shown that $\Delta_{\mathrm{NSym}} \circ F = (F \otimes F) \circ \Delta_{T(V)}$. Combining this with the equality $\epsilon_{\mathrm{NSym}} \circ F = \epsilon_{T(V)}$ (whose proof is similar but yet simpler), we conclude that F is a **k**-coalgebra homomorphism, thus a **k**-bialgebra homomorphism, hence a **k**-Hopf algebra homomorphism (by Corollary 1.4.27), therefore a **k**-Hopf algebra isomorphism (since it is a **k**-module isomorphism). This solves Exercise 5.4.12(j).

(k) Define the map F as in Exercise 5.4.12(j). Then, Exercise 5.4.12(j) shows that F is a Hopf algebra isomorphism, hence a **k**-module isomorphism.

We can endow the **k**-module V with a grading by assigning to each basis vector $\mathfrak{b}_n$ the degree n. Then, V is of finite type and satisfies $V_0 = 0$, and thus $T(V)$ is a connected graded **k**-Hopf algebra.

The element Ψ_n of NSym is homogeneous of degree n for every positive integer n. (This follows from the definition of Ψ_n.)

The map f is graded (since it sends every basis vector $\mathfrak{b}_n$ of V to the vector $\Psi_n \in \mathrm{NSym}$, which is homogeneous of the same degree n as $\mathfrak{b}_n$). Hence, the map F (being the **k**-algebra homomorphism $T(V) \to \mathrm{NSym}$ induced by f) is also graded. It is well-known that if a **k**-module isomorphism is graded, then it is an isomorphism of graded **k**-modules. Thus, F is an isomorphism of graded **k**-modules (since F is a **k**-module isomorphism and is graded), hence an isomorphism of graded Hopf algebras (since F is a Hopf algebra isomorphism). Thus, $T(V) \cong \mathrm{NSym}$ as graded Hopf algebras. Therefore, $T(V)^o \cong \mathrm{NSym}^o \cong \mathrm{QSym}$ (since $\mathrm{NSym} = \mathrm{QSym}^o$) as graded Hopf algebras. Hence, $\mathrm{QSym} \cong T(V)^o$ as graded Hopf algebras.

Remark 1.6.9(b) shows that the Hopf algebra $T(V)^o$ is naturally isomorphic to the shuffle algebra $\mathrm{Sh}(V^o)$ as Hopf algebras. But $V^o \cong V$ as **k**-modules (since V is of finite type), and thus $\mathrm{Sh}(V^o) \cong \mathrm{Sh}(V)$ as Hopf algebras. Altogether, we obtain $\mathrm{QSym} \cong T(V)^o \cong \mathrm{Sh}(V^o) \cong \mathrm{Sh}(V)$ as Hopf algebras. This solves Exercise 5.4.12(k).

(l) We recall that

$$\pi\left(R_{(1^i,n-i)}\right) = s_{(n-i,1^i)} \qquad \text{for every positive integer } n \text{ and every } i \in \{0,1,...,n-1\}. \tag{13.130.6}$$

(This has been proven during the solution to Exercise 5.4.12(g).) Also, Theorem 5.4.10(b) (applied to $\alpha = (1^i)$) yields that

$$\pi\left(R_{(1^i)}\right) = s_{(1^i)} = e_i \qquad \text{for every } i \in \mathbb{N}. \tag{13.130.7}$$

In our solution to Exercise 5.4.12(a), we have shown that

$$R_{(1^i)}H_{n-i} = R_{(1^i,n-i)} + R_{(1^{i-1},n-i+1)} \qquad \text{for every positive integer } n \text{ and every } i \in \{1,2,...,n-1\}. \tag{13.130.8}$$

Now, we are ready to solve parts (a) and (b) of Exercise 2.9.14 anew.

Alternative solution to Exercise 2.9.14(a): Let n and m be positive integers. We need to prove that $e_n h_m = s_{(m+1,1^{n-1})} + s_{(m,1^n)}$.

Applying (13.130.8) to $n+m$ and n instead of n and i, we obtain $R_{(1^n)}H_{(n+m)-n} = R_{(1^n,(n+m)-n)} + R_{(1^{n-1},(n+m)-n+1)} = R_{(1^n,(n+m)-n)} + R_{(1^{n-1},(n+m)-(n-1))}$ (since $(n+m)-n+1 = (n+m)-(n-1)$). Applying the map π to both sides of this equality, we obtain

$$\begin{aligned}
\pi\left(R_{(1^n)}H_{(n+m)-n}\right) &= \pi\left(R_{(1^n,(n+m)-n)} + R_{(1^{n-1},(n+m)-(n-1))}\right) \\
&= \underbrace{\pi\left(R_{(1^n,(n+m)-n)}\right)}_{\substack{=s_{((n+m)-n,1^n)} \\ \text{(by (13.130.6), applied to} \\ n+m \text{ and } n \text{ instead of } n \text{ and } i)}} + \underbrace{\pi\left(R_{(1^{n-1},(n+m)-(n-1))}\right)}_{\substack{=s_{((n+m)-(n-1),1^{n-1})} \\ \text{(by (13.130.6), applied to} \\ n+m \text{ and } n-1 \text{ instead of } n \text{ and } i)}} \\
&= s_{((n+m)-n,1^n)} + s_{((n+m)-(n-1),1^{n-1})} \\
&= s_{(m,1^n)} + s_{(m+1,1^{n-1})} \qquad (\text{since } (n+m)-n = m \text{ and } (n+m)-(n-1) = m+1) \\
&= s_{(m+1,1^{n-1})} + s_{(m,1^n)}.
\end{aligned}$$

Compared with

$$\begin{aligned}\pi\left(R_{(1^n)}H_{(n+m)-n}\right) &= \underbrace{\pi\left(R_{(1^n)}\right)}_{\substack{=e_n\\ \text{(by (13.130.7), applied to}\\ n\text{ instead of }i)}} \cdot \pi\left(\underbrace{H_{(n+m)-n}}_{=H_m}\right) \qquad \text{(since }\pi\text{ is a }\mathbf{k}\text{-algebra morphism)}\\ &= e_n \cdot \underbrace{\pi\left(H_m\right)}_{\substack{=h_m\\ \text{(by the definition of }\pi)}} = e_n h_m,\end{aligned}$$

this yields $e_n h_m = s_{(m+1,1^{n-1})} + s_{(m,1^n)}$. Thus, Exercise 2.9.14(a) is solved again.

Alternative solution to Exercise 2.9.14(b): Let $a \in \mathbb{N}$ and $b \in \mathbb{N}$. Applying Exercise 5.4.12(b) to $n = a+b+1$ and $i = b$, we obtain

$$(-1)^b R_{(1^b,(a+b+1)-b)} = \sum_{j=0}^{b} S\left(H_j\right) H_{(a+b+1)-j} = \sum_{j=0}^{b} S\left(H_{b-j}\right) H_{(a+b+1)-(b-j)}$$

(here, we substituted $b-j$ for j in the sum). Multiplying both sides of this equality by $(-1)^b$, we obtain

$$\begin{aligned}R_{(1^b,(a+b+1)-b)} &= (-1)^b \sum_{j=0}^{b} S\left(H_{b-j}\right) \underbrace{H_{(a+b+1)-(b-j)}}_{\substack{=H_{a+j+1}\\ \text{(since }(a+b+1)-(b-j)=a+j+1)}} = (-1)^b \sum_{j=0}^{b} S\left(H_{b-j}\right) H_{a+j+1}\\ &= (-1)^b \sum_{i=0}^{b} S\left(H_{b-i}\right) H_{a+i+1} \qquad \text{(here, we renamed the summation index } j \text{ as } i).\end{aligned}$$

Applying the map π to both sides of this equality, we obtain

$$\begin{aligned}\pi\left(R_{(1^b,(a+b+1)-b)}\right) &= \pi\left((-1)^b \sum_{i=0}^{b} S\left(H_{b-i}\right) H_{a+i+1}\right) = (-1)^b \sum_{i=0}^{b} S\left(\underbrace{\pi\left(H_{b-i}\right)}_{\substack{=h_{b-i}\\ \text{(by the definition of }\pi)}}\right) \underbrace{\pi\left(H_{a+i+1}\right)}_{\substack{=h_{a+i+1}\\ \text{(by the definition of }\pi)}}\\ &\qquad \text{(since }\pi\text{ is a Hopf algebra homomorphism)}\\ &= (-1)^b \sum_{i=0}^{b} \underbrace{S\left(h_{b-i}\right)}_{\substack{=(-1)^{b-i}e_{b-i}\\ \text{(by Proposition 2.4.1(iii),}\\ \text{applied to }n=b-i)}} h_{a+i+1}\\ &= (-1)^b \sum_{i=0}^{b} (-1)^{b-i} e_{b-i} h_{a+i+1} = \sum_{i=0}^{b} (-1)^i h_{a+i+1} e_{b-i}.\end{aligned}$$

Thus,

$$\begin{aligned}\sum_{i=0}^{b} (-1)^i h_{a+i+1} e_{b-i} &= \pi\left(R_{(1^b,(a+b+1)-b)}\right) = s_{((a+b+1)-b,1^b)}\\ &\qquad \text{(by (13.130.6), applied to } n = a+b+1 \text{ and } i = b)\\ &= s_{(a+1,1^b)}.\end{aligned}$$

Thus, Exercise 2.9.14(b) is once again solved.

13.131. **Solution to Exercise 5.4.13.** *Solution to Exercise 5.4.13.*

(a) The solution of Exercise 5.4.13(a) can be obtained from the solution of Exercise 2.9.9(a) upon replacing $\mathbf{f}_n$ by $\mathbf{F}_n$.

(b) The solution of Exercise 5.4.13(b) can be obtained from the solution of Exercise 2.9.9(b) upon replacing $\mathbf{f}_n$, $\mathbf{f}_m$, $\mathbf{f}_{nm}$ and Λ by $\mathbf{F}_n$, $\mathbf{F}_m$, $\mathbf{F}_{nm}$ and QSym.

(c) The solution of Exercise 5.4.13(c) can be obtained from the solution of Exercise 2.9.9(c) upon replacing $\mathbf{f}_1$ and Λ by $\mathbf{F}_1$ and QSym.

(d) Let $n \in \{1, 2, 3, \ldots\}$ and $(\beta_1, \beta_2, \ldots, \beta_s) \in \operatorname{Comp}$. The definition of $M_{(\beta_1,\beta_2,\ldots,\beta_s)}$ yields that $M_{(\beta_1,\beta_2,\ldots,\beta_s)} = \sum_{i_1<i_2<\cdots<i_s} x_{i_1}^{\beta_1} x_{i_2}^{\beta_2} \cdots x_{i_s}^{\beta_s}$ (where the sum is over all s-tuples $(i_1, i_2, \ldots, i_s)$ of positive integers satisfying $i_1 < i_2 < \cdots < i_s$). Applying the map $\mathbf{F}_n$ to both sides of this equality, we obtain

$$\begin{aligned}
\mathbf{F}_n\left(M_{(\beta_1,\beta_2,\ldots,\beta_s)}\right) &= \mathbf{F}_n\left(\sum_{i_1<i_2<\cdots<i_s} x_{i_1}^{\beta_1} x_{i_2}^{\beta_2} \cdots x_{i_s}^{\beta_s}\right) \\
&= \left(\sum_{i_1<i_2<\cdots<i_s} x_{i_1}^{\beta_1} x_{i_2}^{\beta_2} \cdots x_{i_s}^{\beta_s}\right)(x_1^n, x_2^n, x_3^n, \ldots) \qquad \text{(by the definition of } \mathbf{F}_n\text{)} \\
&= \sum_{i_1<i_2<\cdots<i_s} \left(x_{i_1}^n\right)^{\beta_1} \left(x_{i_2}^n\right)^{\beta_2} \cdots \left(x_{i_s}^n\right)^{\beta_s} = \sum_{i_1<i_2<\cdots<i_s} x_{i_1}^{n\beta_1} x_{i_2}^{n\beta_2} \cdots x_{i_s}^{n\beta_s}.
\end{aligned}$$

Compared with

$$M_{(n\beta_1,n\beta_2,\ldots,n\beta_s)} = \sum_{i_1<i_2<\cdots<i_s} x_{i_1}^{n\beta_1} x_{i_2}^{n\beta_2} \cdots x_{i_s}^{n\beta_s} \qquad \left(\text{by the definition of } M_{(n\beta_1,n\beta_2,\ldots,n\beta_s)}\right),$$

this yields $\mathbf{F}_n\left(M_{(\beta_1,\beta_2,\ldots,\beta_s)}\right) = M_{(n\beta_1,n\beta_2,\ldots,n\beta_s)}$. This solves Exercise 5.4.13(d).

(e) Fix $n \in \{1, 2, 3, \ldots\}$. We now know that $\mathbf{F}_n$ is a $\mathbf{k}$-algebra homomorphism (due to Exercise 5.4.13(a)), thus a $\mathbf{k}$-linear map.

Let $\alpha \in \operatorname{Comp}$. Write α in the form $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$. Then,

$$\Delta M_\alpha = \sum_{k=0}^{\ell} M_{(\alpha_1,\alpha_2,\ldots,\alpha_k)} \otimes M_{(\alpha_{k+1},\alpha_{k+2},\ldots,\alpha_\ell)} \tag{13.131.1}$$

(according to Proposition 5.1.7). Applying the map $\mathbf{F}_n \otimes \mathbf{F}_n$ to both sides of this equality, we obtain

$$\begin{aligned}
(\mathbf{F}_n \otimes \mathbf{F}_n)(\Delta M_\alpha) &= (\mathbf{F}_n \otimes \mathbf{F}_n)\left(\sum_{k=0}^{\ell} M_{(\alpha_1,\alpha_2,\ldots,\alpha_k)} \otimes M_{(\alpha_{k+1},\alpha_{k+2},\ldots,\alpha_\ell)}\right) \\
&= \sum_{k=0}^{\ell} \underbrace{\mathbf{F}_n\left(M_{(\alpha_1,\alpha_2,\ldots,\alpha_k)}\right)}_{\substack{=M_{(n\alpha_1,n\alpha_2,\ldots,n\alpha_k)} \\ \text{(by Exercise 5.4.13(d), applied to} \\ (\alpha_1,\alpha_2,\ldots,\alpha_k) \text{ instead of } (\beta_1,\beta_2,\ldots,\beta_s))}} \otimes \underbrace{\mathbf{F}_n\left(M_{(\alpha_{k+1},\alpha_{k+2},\ldots,\alpha_\ell)}\right)}_{\substack{=M_{(n\alpha_{k+1},n\alpha_{k+2},\ldots,n\alpha_\ell)} \\ \text{(by Exercise 5.4.13(d), applied to} \\ (\alpha_{k+1},\alpha_{k+2},\ldots,\alpha_\ell) \text{ instead of } (\beta_1,\beta_2,\ldots,\beta_s))}} \\
&= \sum_{k=0}^{\ell} M_{(n\alpha_1,n\alpha_2,\ldots,n\alpha_k)} \otimes M_{(n\alpha_{k+1},n\alpha_{k+2},\ldots,n\alpha_\ell)}. \qquad (13.131.2)
\end{aligned}$$

But

$$\begin{aligned}(\Delta \circ \mathbf{F}_n)(M_\alpha) &= \Delta\left(\mathbf{F}_n\left(\underbrace{M_\alpha}_{\substack{=M_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\\ (\text{since } \alpha=(\alpha_1,\alpha_2,\ldots,\alpha_\ell))}}\right)\right) = \Delta\left(\underbrace{\mathbf{F}_n\left(M_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\right)}_{\substack{=M_{(n\alpha_1,n\alpha_2,\ldots,n\alpha_\ell)}\\ (\text{by Exercise 5.4.13(d), applied to}\\ (\alpha_1,\alpha_2,\ldots,\alpha_\ell) \text{ instead of } (\beta_1,\beta_2,\ldots,\beta_s))}}\right)\\
&= \Delta M_{(n\alpha_1,n\alpha_2,\ldots,n\alpha_\ell)} = \sum_{k=0}^{\ell} M_{(n\alpha_1,n\alpha_2,\ldots,n\alpha_k)} \otimes M_{(n\alpha_{k+1},n\alpha_{k+2},\ldots,n\alpha_\ell)}\\
&\qquad \left(\begin{array}{c}\text{by (13.131.1), applied to } (n\alpha_1,n\alpha_2,\ldots,n\alpha_\ell) \text{ and}\\ (n\alpha_1,n\alpha_2,\ldots,n\alpha_\ell) \text{ instead of } \alpha \text{ and } (\alpha_1,\alpha_2,\ldots,\alpha_\ell)\end{array}\right)\\
&= (\mathbf{F}_n \otimes \mathbf{F}_n)(\Delta M_\alpha) \qquad (\text{by (13.131.2)})\\
&= ((\mathbf{F}_n \otimes \mathbf{F}_n) \circ \Delta)(M_\alpha).\end{aligned}$$

Let us now forget that we fixed α. We thus have shown that

$$(\Delta \circ \mathbf{F}_n)(M_\alpha) = ((\mathbf{F}_n \otimes \mathbf{F}_n) \circ \Delta)(M_\alpha) \qquad \text{for every } \alpha \in \operatorname{Comp}. \tag{13.131.3}$$

Now, let us recall that the family $(M_\alpha)_{\alpha\in\operatorname{Comp}}$ is a basis of the $\mathbf{k}$-module QSym. The two $\mathbf{k}$-linear maps $\Delta \circ \mathbf{F}_n$ and $(\mathbf{F}_n \otimes \mathbf{F}_n) \circ \Delta$ are equal to each other on this basis (according to (13.131.3)), and therefore must be identical (because if two $\mathbf{k}$-linear maps from the same domain are equal to each other on a basis of their domain, then these two maps must be identical). In other words, $\Delta \circ \mathbf{F}_n = (\mathbf{F}_n \otimes \mathbf{F}_n) \circ \Delta$. We can prove (using a similar but simpler argument) that $\epsilon \circ \mathbf{F}_n = \epsilon$. Thus, the map $\mathbf{F}_n$ is a $\mathbf{k}$-coalgebra homomorphism (since it is $\mathbf{k}$-linear and satisfies $\Delta \circ \mathbf{F}_n = (\mathbf{F}_n \otimes \mathbf{F}_n) \circ \Delta$ and $\epsilon \circ \mathbf{F}_n = \epsilon$).

We now know that $\mathbf{F}_n$ is a $\mathbf{k}$-algebra homomorphism and a $\mathbf{k}$-coalgebra homomorphism. Hence, $\mathbf{F}_n$ is a $\mathbf{k}$-bialgebra homomorphism, thus a Hopf algebra homomorphism (due to Corollary 1.4.27). This solves Exercise 5.4.13(e).

(f) Let $n \in \{1,2,3,\ldots\}$. For every $a \in \Lambda$, we have

$$\begin{aligned}(\mathbf{F}_n\mid_\Lambda)(a) = \mathbf{F}_n(a) &= a(x_1^n, x_2^n, x_3^n, \ldots) \qquad (\text{by the definition of } \mathbf{F}_n)\\
&= \mathbf{f}_n(a) \qquad (\text{since } \mathbf{f}_n(a) = a(x_1^n, x_2^n, x_3^n, \ldots) \text{ (by the definition of } \mathbf{f}_n)).\end{aligned}$$

Thus, $\mathbf{F}_n\mid_\Lambda = \mathbf{f}_n$. This solves Exercise 5.4.13(f).

(g) The solution of Exercise 5.4.13(g) can be obtained from the solution of Exercise 2.9.9(f) upon replacing $\mathbf{f}_p$ and Λ by $\mathbf{F}_p$ and QSym, and replacing the word "symmetric" by "quasisymmetric".

(h) *Alternative solution of Exercise 2.9.9(d).* Fix $n \in \{1,2,3,\ldots\}$. Exercise 5.4.13(f) yields that $\mathbf{F}_n\mid_\Lambda = \mathbf{f}_n$. Hence, $\mathbf{f}_n = \mathbf{F}_n\mid_\Lambda$ is the restriction of $\mathbf{F}_n$ to the Hopf subalgebra Λ of QSym. Thus, $\mathbf{f}_n$ is the restriction of a Hopf algebra homomorphism to the Hopf subalgebra Λ of QSym (since $\mathbf{F}_n$ is a Hopf algebra homomorphism (by Exercise 5.4.13(e))). Consequently, $\mathbf{f}_n$ is a Hopf algebra homomorphism itself (since the restriction of a Hopf algebra homomorphism to a Hopf subalgebra must always be a Hopf algebra homomorphism). This gives a new solution to Exercise 2.9.9(d). Thus, Exercise 5.4.13(h) is solved.

13.132. **Solution to Exercise 5.4.14.** *Solution to Exercise 5.4.14.* Let us first notice that every positive integer n satisfies

$$\mathbf{V}_n(H_m) = \begin{cases} H_{m/n}, & \text{if } n \mid m;\\ 0, & \text{if } n \nmid m\end{cases} \qquad \text{for every } m \in \mathbb{N} \tag{13.132.1}$$

[927].

[927] *Proof.* To obtain a proof of (13.132.1), it is enough to repeat the proof of (13.87.1), making just the following changes:

- replacing every h_i by H_i;
- replacing $\mathbf{v}_n$ by $\mathbf{V}_n$.

Recall that NSym is (isomorphic to) the free associative algebra with generators $H_1, H_2, H_3, \ldots$ (according to (5.4.1)). Hence, the elements $H_1, H_2, H_3, \ldots$ generate the $\mathbf{k}$-algebra NSym. In other words,

$$\text{the family } \left(H_r\right)_{r\geq 1} \text{ generates the } \mathbf{k}\text{-algebra NSym}. \tag{13.132.2}$$

(e) A solution to Exercise 5.4.14(e) can be obtained by copying the solution of Exercise 2.9.10(e) and making the following changes:

- Replace every appearance of $\mathbf{v}_n$ by $\mathbf{V}_n$.
- Replace every appearance of Λ by NSym.
- Replace every appearance of h_j (for some $j \in \mathbb{N}$) by H_j.
- Replace the reference to Proposition 2.3.6(iii) by a reference to (5.4.2).
- Replace the reference to Proposition 2.4.1 by a reference to (13.132.2).
- Replace every reference to (13.87.1) by a reference to (13.132.1).

(c) A solution to Exercise 5.4.14(c) can be obtained by copying the solution of Exercise 2.9.10(c) and making the following changes:

- Replace every appearance of $\mathbf{v}_j$ (for some positive integer j) by $\mathbf{V}_j$.
- Replace every appearance of Λ by NSym.
- Replace every appearance of h_j (for some $j \in \mathbb{N}$) by H_j.
- Replace the reference to Proposition 2.4.1 by a reference to (13.132.2).

(d) A solution to Exercise 5.4.14(d) can be obtained by copying the solution of Exercise 2.9.10(d) and making the following changes:

- Replace every appearance of $\mathbf{v}_1$ by $\mathbf{V}_1$.
- Replace every appearance of Λ by NSym.
- Replace every appearance of h_j (for some $j \in \mathbb{N}$) by H_j.
- Replace the reference to Proposition 2.4.1 by a reference to (13.132.2).

(a) Here is one of several possible solutions of Exercise 5.4.14(a):[928] Define a $\mathbf{k}$-linear map $E : \text{NSym} \to \text{NSym}$ as in Exercise 1.5.14 (but with NSym instead of A). Every positive integer n satisfies

$$\Psi_n = \left(S \star E\right)\left(H_n\right) \tag{13.132.3}$$

(according to Exercise 5.4.12(c)).

Fix a positive integer n. Let us make some auxiliary observations first:

- Every composition $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ satisfies

$$H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)} = H_{\alpha_1} H_{\alpha_2} \cdots H_{\alpha_\ell}. \tag{13.132.4}$$

[929]

- If $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ is a composition such that (not every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$), then

$$\mathbf{V}_n\left(H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\right) = 0. \tag{13.132.5}$$

[930]

[928] Another solution (which the reader can easily find) proceeds by making some relatively straightforward modifications to the solution of Exercise 2.9.10(a). (One needs to keep in mind that NSym, unlike Λ, is not commutative – but this does not prevent us from doing things such as substituting t^n for t in a power series over NSym (since t^n is a central element of NSym $[[t]]$).)

[929] This is precisely the equality (5.4.3), and has been proven before.

[930] *Proof of (13.132.5):* Let $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ be a composition such that (not every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$). Then, there exists an $i \in \{1, 2, \ldots, \ell\}$ satisfying $n \nmid \alpha_i$ (since not every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$). Consider this i. We have

$$\begin{aligned}\mathbf{V}_n\left(H_{\alpha_i}\right) &= \begin{cases} H_{\alpha_i/n}, & \text{if } n \mid \alpha_i; \\ 0, & \text{if } n \nmid \alpha_i \end{cases} \qquad \left(\text{by the definition of } \mathbf{V}_n\left(H_{\alpha_i}\right)\right) \\ &= 0 \qquad \left(\text{since } n \nmid \alpha_i\right).\end{aligned}$$

But (13.132.4) yields $H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)} = H_{\alpha_1} H_{\alpha_2} \cdots H_{\alpha_\ell}$. Applying $\mathbf{V}_n$ to both sides of this equality, we obtain

$$\begin{aligned}\mathbf{V}_n\left(H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\right) &= \mathbf{V}_n\left(H_{\alpha_1} H_{\alpha_2} \cdots H_{\alpha_\ell}\right) = \mathbf{V}_n\left(H_{\alpha_1}\right) \mathbf{V}_n\left(H_{\alpha_2}\right) \cdots \mathbf{V}_n\left(H_{\alpha_\ell}\right) \\ &\qquad \left(\text{since } \mathbf{V}_n \text{ is a } \mathbf{k}\text{-algebra homomorphism}\right) \\ &= 0 \qquad \left(\begin{array}{c}\text{since at least one factor of the product} \\ \mathbf{V}_n\left(H_{\alpha_1}\right) \mathbf{V}_n\left(H_{\alpha_2}\right) \cdots \mathbf{V}_n\left(H_{\alpha_\ell}\right) \text{ is 0 (namely, the factor } \mathbf{V}_n\left(H_{\alpha_i}\right)\text{)}\end{array}\right).\end{aligned}$$

- If $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ is a composition such that (every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$), then

$$\mathbf{V}_n\left(H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\right) = H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}. \tag{13.132.6}$$

[931]

- We have

$$\mathbf{V}_n \circ E = n \cdot (E \circ \mathbf{V}_n) \tag{13.132.7}$$

(as endomorphisms of NSym). [932]

- We have

$$\mathbf{V}_n \circ (S \star E) = n \cdot ((S \star E) \circ \mathbf{V}_n) \tag{13.132.10}$$

This proves (13.132.5).

[931] *Proof of (13.132.6):* Let $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$ be a composition such that (every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$). Then, $(\alpha_1/n, \alpha_2/n, \ldots, \alpha_\ell/n)$ is a composition. Therefore, (13.132.4) (applied to $(\alpha_1/n, \alpha_2/n, \ldots, \alpha_\ell/n)$ instead of $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$) yields $H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)} = H_{\alpha_1/n}H_{\alpha_2/n}\cdots H_{\alpha_\ell/n}$.

But every $i \in \{1, 2, \ldots, \ell\}$ satisfies

$$\begin{aligned}\mathbf{V}_n\left(H_{\alpha_i}\right) &= \begin{cases} H_{\alpha_i/n}, & \text{if } n \mid \alpha_i; \\ 0, & \text{if } n \nmid \alpha_i \end{cases} && \left(\text{by the definition of } \mathbf{V}_n\left(H_{\alpha_i}\right)\right) \\ &= H_{\alpha_i/n} && \left(\text{since } n \mid \alpha_i\right).\end{aligned}$$

Multiplying these equalities for all $i \in \{1, 2, \ldots, \ell\}$, we obtain

$$\mathbf{V}_n\left(H_{\alpha_1}\right)\mathbf{V}_n\left(H_{\alpha_2}\right)\cdots\mathbf{V}_n\left(H_{\alpha_\ell}\right) = H_{\alpha_1/n}H_{\alpha_2/n}\cdots H_{\alpha_\ell/n}.$$

But (13.132.4) yields $H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)} = H_{\alpha_1}H_{\alpha_2}\cdots H_{\alpha_\ell}$. Applying $\mathbf{V}_n$ to both sides of this equality, we obtain

$$\begin{aligned}\mathbf{V}_n\left(H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\right) &= \mathbf{V}_n\left(H_{\alpha_1}H_{\alpha_2}\cdots H_{\alpha_\ell}\right) = \mathbf{V}_n\left(H_{\alpha_1}\right)\mathbf{V}_n\left(H_{\alpha_2}\right)\cdots\mathbf{V}_n\left(H_{\alpha_\ell}\right) \\ &\qquad \left(\text{since } \mathbf{V}_n \text{ is a } \mathbf{k}\text{-algebra homomorphism}\right) \\ &= H_{\alpha_1/n}H_{\alpha_2/n}\cdots H_{\alpha_\ell/n} = H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}.\end{aligned}$$

This proves (13.132.6).

[932] *Proof of (13.132.7):* Let us show that

$$\left(\mathbf{V}_n \circ E\right)\left(H_\alpha\right) = \left(n \cdot \left(E \circ \mathbf{V}_n\right)\right)\left(H_\alpha\right) \qquad \text{for every } \alpha \in \operatorname{Comp}. \tag{13.132.8}$$

Proof of (13.132.8): Let $\alpha \in \operatorname{Comp}$. Then, H_α is a homogeneous element of NSym of degree $\deg\left(H_\alpha\right) = |\alpha|$. Thus, the definition of $E\left(H_\alpha\right)$ yields $E\left(H_\alpha\right) = \underbrace{\left(\deg\left(H_\alpha\right)\right)}_{=|\alpha|} \cdot H_\alpha = |\alpha| \cdot H_\alpha$. Now,

$$\left(\mathbf{V}_n \circ E\right)\left(H_\alpha\right) = \mathbf{V}_n\left(\underbrace{E\left(H_\alpha\right)}_{=|\alpha|\cdot H_\alpha}\right) = \mathbf{V}_n\left(|\alpha| \cdot H_\alpha\right) = |\alpha| \cdot \mathbf{V}_n\left(H_\alpha\right) \qquad \left(\text{since the map } \mathbf{V}_n \text{ is } \mathbf{k}\text{-linear}\right).$$

Now, let us write the composition α in the form $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$. We distinguish between two cases:

Case 1: Not every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$.

Case 2: Every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$.

Let us first consider Case 1. In this case, not every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$. Thus, (13.132.5) yields $\mathbf{V}_n\left(H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\right) = 0$. Since $(\alpha_1, \alpha_2, \ldots, \alpha_\ell) = \alpha$, this rewrites as $\mathbf{V}_n\left(H_\alpha\right) = 0$. Thus, $\left(\mathbf{V}_n \circ E\right)\left(H_\alpha\right) = |\alpha| \cdot \underbrace{\mathbf{V}_n\left(H_\alpha\right)}_{=0} = 0$. Compared with

$$\left(n \cdot \left(E \circ \mathbf{V}_n\right)\right)\left(H_\alpha\right) = n \cdot \underbrace{\left(E \circ \mathbf{V}_n\right)\left(H_\alpha\right)}_{=E\left(\mathbf{V}_n\left(H_\alpha\right)\right)} = n \cdot E\left(\underbrace{\mathbf{V}_n\left(H_\alpha\right)}_{=0}\right) = n \cdot \underbrace{E\left(0\right)}_{\substack{=0 \\ (\text{since } E \text{ is } \mathbf{k}\text{-linear})}} = 0,$$

this yields $\left(\mathbf{V}_n \circ E\right)\left(H_\alpha\right) = \left(n \cdot \left(E \circ \mathbf{V}_n\right)\right)\left(H_\alpha\right)$. Hence, (13.132.8) is proven in Case 1.

Let us now consider Case 2. In this case, every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \alpha_i$. Thus, (13.132.6) yields $\mathbf{V}_n\left(H_{(\alpha_1,\alpha_2,\ldots,\alpha_\ell)}\right) = H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}$. Since $(\alpha_1, \alpha_2, \ldots, \alpha_\ell) = \alpha$, this rewrites as $\mathbf{V}_n\left(H_\alpha\right) = H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}$. Thus,

$$\left(\mathbf{V}_n \circ E\right)\left(H_\alpha\right) = |\alpha| \cdot \underbrace{\mathbf{V}_n\left(H_\alpha\right)}_{=H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}} = |\alpha| \cdot H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}. \tag{13.132.9}$$

On the other hand, $H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}$ is a homogeneous element of NSym of degree $\deg\left(H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}\right) = \left|(\alpha_1/n, \alpha_2/n, \ldots, \alpha_\ell/n)\right| = \left|\underbrace{(\alpha_1, \alpha_2, \ldots, \alpha_\ell)}_{=\alpha}\right|/n = |\alpha|/n$. Hence, the definition of $E\left(H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}\right)$ yields (where S, as usual, denotes the antipode of NSym). [933]

$E\left(H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}\right) = \underbrace{\left(\deg\left(H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}\right)\right)}_{=|\alpha|/n} \cdot H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)} = (|\alpha|/n)\cdot H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}$. Now,

$$\begin{aligned}
\left(n\cdot\left(E\circ\mathbf{V}_n\right)\right)\left(H_\alpha\right) &= n\cdot\underbrace{\left(E\circ\mathbf{V}_n\right)\left(H_\alpha\right)}_{=E(\mathbf{V}_n(H_\alpha))} = n\cdot E\left(\underbrace{\mathbf{V}_n\left(H_\alpha\right)}_{=H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}}\right) \\
&= n\cdot\underbrace{E\left(H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}\right)}_{=(|\alpha|/n)\cdot H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}} = n\cdot(|\alpha|/n)\cdot H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)} \\
&= |\alpha|\cdot H_{(\alpha_1/n,\alpha_2/n,\ldots,\alpha_\ell/n)}.
\end{aligned}$$

Compared with (13.132.9), this yields $\left(\mathbf{V}_n\circ E\right)\left(H_\alpha\right) = \left(n\cdot\left(E\circ\mathbf{V}_n\right)\right)\left(H_\alpha\right)$. Hence, (13.132.8) is proven in Case 2.

Thus, (13.132.8) is proven in both Cases 1 and 2. Since these two Cases cover all possibilities, this shows that (13.132.8) always holds.

Now, $\left(H_\alpha\right)_{\alpha\in\mathrm{Comp}}$ is a basis of the $\mathbf{k}$-module NSym. The equality (13.132.8) shows that the two $\mathbf{k}$-linear maps $\mathbf{V}_n\circ E$ and $n\cdot\left(E\circ\mathbf{V}_n\right)$ are equal to each other on every element of this basis. Hence, these two maps $\mathbf{V}_n\circ E$ and $n\cdot\left(E\circ\mathbf{V}_n\right)$ are identical (because if two $\mathbf{k}$-linear maps having the same domain are equal to each other on every element of some basis of this domain, then these two maps must be identical). In other words, $\mathbf{V}_n\circ E = n\cdot\left(E\circ\mathbf{V}_n\right)$. This proves (13.132.7).

[933] *Proof of (13.132.10):* We have $S\star E = m\circ(S\otimes E)\circ\Delta$ (by the definition of convolution). But we know (from Exercise 5.4.14(e)) that $\mathbf{V}_n$ is a Hopf algebra homomorphism; thus, $\mathbf{V}_n\circ S = S\circ\mathbf{V}_n$. Also, $\mathbf{V}_n$ is a $\mathbf{k}$-coalgebra homomorphism (since $\mathbf{V}_n$ is a Hopf algebra homomorphism); therefore, $\left(\mathbf{V}_n\otimes\mathbf{V}_n\right)\circ\Delta = \Delta\circ\mathbf{V}_n$. Finally, $\mathbf{V}_n$ is a $\mathbf{k}$-algebra homomorphism; thus, $\mathbf{V}_n\circ m = m\circ\left(\mathbf{V}_n\otimes\mathbf{V}_n\right)$. Now,

$$\begin{aligned}
\mathbf{V}_n\circ\left(\underbrace{S\star E}_{=m\circ(S\otimes E)\circ\Delta}\right) &= \underbrace{\mathbf{V}_n\circ m}_{=m\circ(\mathbf{V}_n\otimes\mathbf{V}_n)}\circ(S\otimes E)\circ\Delta = m\circ\underbrace{\left(\mathbf{V}_n\otimes\mathbf{V}_n\right)\circ(S\otimes E)}_{=(\mathbf{V}_n\circ S)\otimes(\mathbf{V}_n\circ E)}\circ\Delta \\
&= m\circ\left(\underbrace{\left(\mathbf{V}_n\circ S\right)}_{=S\circ\mathbf{V}_n}\otimes\underbrace{\left(\mathbf{V}_n\circ E\right)}_{\substack{=n\cdot(E\circ\mathbf{V}_n) \\ \text{(by (13.132.7))}}}\right)\circ\Delta = m\circ\left(\left(S\circ\mathbf{V}_n\right)\otimes\left(n\cdot\left(E\circ\mathbf{V}_n\right)\right)\right)\circ\Delta \\
&= n\cdot\left(m\circ\underbrace{\left(\left(S\circ\mathbf{V}_n\right)\otimes\left(E\circ\mathbf{V}_n\right)\right)}_{=(S\otimes E)\circ(\mathbf{V}_n\otimes\mathbf{V}_n)}\circ\Delta\right) \qquad \text{(since n is just a scalar factor)} \\
&= n\cdot\left(m\circ(S\otimes E)\circ\underbrace{\left(\mathbf{V}_n\otimes\mathbf{V}_n\right)\circ\Delta}_{=\Delta\circ\mathbf{V}_n}\right) = n\cdot\left(\underbrace{m\circ(S\otimes E)\circ\Delta}_{\substack{=S\star E \\ \text{(since } S\star E=m\circ(S\otimes E)\circ\Delta)}}\circ\mathbf{V}_n\right) = n\cdot\left(\left(S\star E\right)\circ\mathbf{V}_n\right).
\end{aligned}$$

This proves (13.132.10).

But fix a positive integer m. We have $\Psi_m = (S \star E)(H_m)$ (by (13.132.3), applied to m instead of n) and thus

$$\begin{aligned}
\mathbf{V}_n\left(\underbrace{\Psi_m}_{=(S\star E)(H_m)}\right) &= \mathbf{V}_n\left((S\star E)(H_m)\right) = \underbrace{\left(\mathbf{V}_n \circ (S\star E)\right)}_{\substack{=n\cdot((S\star E)\circ \mathbf{V}_n) \\ \text{(by (13.132.10))}}}(H_m) \\
&= \left(n\cdot\left((S\star E)\circ \mathbf{V}_n\right)\right)(H_m) = n\cdot \underbrace{\left((S\star E)\circ \mathbf{V}_n\right)(H_m)}_{=(S\star E)(\mathbf{V}_n(H_m))} \\
&= n\cdot (S\star E)\left(\underbrace{\mathbf{V}_n(H_m)}_{\substack{=\begin{cases} H_{m/n}, & \text{if } n\mid m; \\ 0, & \text{if } n\nmid m\end{cases} \\ \text{(by (13.132.1))}}}\right) = n\cdot (S\star E)\left(\begin{cases} H_{m/n}, & \text{if } n\mid m; \\ 0, & \text{if } n\nmid m\end{cases}\right) \\
&= \begin{cases} n\cdot (S\star E)\left(H_{m/n}\right), & \text{if } n\mid m; \\ n\cdot (S\star E)(0), & \text{if } n\nmid m\end{cases} \\
&= \begin{cases} n\cdot (S\star E)\left(H_{m/n}\right), & \text{if } n\mid m; \\ 0, & \text{if } n\nmid m\end{cases} \qquad \left(\text{since } n\cdot \underbrace{(S\star E)(0)}_{=0} = 0\right) \\
&= \begin{cases} n\Psi_{m/n}, & \text{if } n\mid m; \\ 0, & \text{if } n\nmid m\end{cases}
\end{aligned}$$

(because if $n \mid m$, then $(S\star E)\left(H_{m/n}\right) = \Psi_{m/n}$ [934]). This solves Exercise 5.4.14(a).

(b) Recall that a ring of formal power series $R[[t]]$ over a (not necessarily commutative) $\mathbf{k}$-algebra R has a canonical topology which makes it into a topological $\mathbf{k}$-algebra[935]. Thus, in particular, $\operatorname{NSym}[[t]]$ becomes a topological $\mathbf{k}$-algebra. We shall be considering this topology when we speak of continuity.

Assume that $\mathbb{Q}$ is a subring of $\mathbf{k}$.

Define two power series $\widetilde{H}(t)$ and $\xi(t)$ in $\operatorname{NSym}[[t]]$ by

$$\widetilde{H}(t) = \sum_{n\geq 0} H_n t^n;$$
$$\xi(t) = \sum_{n\geq 1} \xi_n t^n = \log\left(\widetilde{H}(t)\right).$$

(Here, the equality $\sum_{n\geq 1} \xi_n t^n = \log\left(\widetilde{H}(t)\right)$ follows from (5.4.6).)

We have $\widetilde{H}(t) = \sum_{n\geq 0} H_n t^n = \sum_{i\geq 0} H_i t^i$ (here, we renamed the summation index n as i) and $\xi(t) = \sum_{n\geq 1} \xi_n t^n = \sum_{i\geq 1} \xi_i t^i$ (here, we renamed the summation index n as i).

Now, let n be a positive integer. The $\mathbf{k}$-algebra homomorphism $\mathbf{V}_n : \operatorname{NSym} \to \operatorname{NSym}$ induces a continuous $\mathbf{k}$-algebra homomorphism $\mathbf{V}_n[[t]] : \operatorname{NSym}[[t]] \to \operatorname{NSym}[[t]]$ given by

$$\left(\mathbf{V}_n[[t]]\right)\left(\sum_{i\in\mathbb{N}} a_i t^i\right) = \sum_{i\in\mathbb{N}} \mathbf{V}_n(a_i)\, t^i \qquad \text{for all } (a_i)_{i\in\mathbb{N}} \in \operatorname{NSym}^{\mathbb{N}}.$$

[934] *Proof.* Assume that $n \mid m$. Then, m/n is a positive integer. Hence, (13.132.3) (applied to m/n instead of n) yields $\Psi_{m/n} = (S\star E)\left(H_{m/n}\right)$, so that $(S\star E)\left(H_{m/n}\right) = \Psi_{m/n}$, qed.

[935] This is proven just as in the case when R is commutative.

This $\mathbf{k}$-algebra homomorphism $\mathbf{V}_n[[t]]$ commutes with taking logarithms (since it is continuous and a $\mathbf{k}$-algebra homomorphism) – i.e., we have

$$(\mathbf{V}_n[[t]])(\log Q) = \log((\mathbf{V}_n[[t]])(Q)) \tag{13.132.11}$$

for every $Q \in \operatorname{NSym}[[t]]$ having constant coefficient 1.

We have $\xi(t) = \sum_{i\geq 1} \xi_i t^i$, thus

$$\sum_{i\geq 1} \xi_i t^i = \xi(t) = \log\left(\underbrace{\widetilde{H}(t)}_{=\sum_{i\geq 0} H_i t^i}\right) = \log\left(\sum_{i\geq 0} H_i t^i\right).$$

We can substitute t^n for t on both sides of this equality[936]. As a result, we obtain

$$\sum_{i\geq 1} \xi_i (t^n)^i = \log\left(\sum_{i\geq 0} H_i (t^n)^i\right). \tag{13.132.12}$$

But $\widetilde{H}(t) = \sum_{i\geq 0} H_i t^i$. Applying the map $\mathbf{V}_n[[t]]$ to both sides of this equality, we obtain

$$\begin{aligned}
(\mathbf{V}_n[[t]])\left(\widetilde{H}(t)\right) &= (\mathbf{V}_n[[t]])\left(\sum_{i\geq 0} H_i t^i\right) = \sum_{i\geq 0} \underbrace{\mathbf{V}_n(H_i)}_{\substack{= \begin{cases} H_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases} \\ \text{(by (13.132.1), applied to } m=i)}} t^i \\
&= \sum_{i\geq 0} \begin{cases} H_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases} \cdot t^i \\
&= \sum_{\substack{i\geq 0; \\ n\mid i}} \underbrace{\begin{cases} H_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases}}_{\substack{=H_{i/n} \\ \text{(since } n\mid i)}} \cdot t^i + \sum_{\substack{i\geq 0; \\ n\nmid i}} \underbrace{\begin{cases} H_{i/n}, & \text{if } n \mid i; \\ 0, & \text{if } n \nmid i \end{cases}}_{\substack{=0 \\ \text{(since } n\nmid i)}} \cdot t^i \\
&= \sum_{\substack{i\geq 0; \\ n\mid i}} H_{i/n} t^i + \underbrace{\sum_{\substack{i\geq 0; \\ n\nmid i}} 0 t^i}_{=0} = \sum_{\substack{i\geq 0; \\ n\mid i}} H_{i/n} t^i \\
&= \sum_{i\geq 0} \underbrace{H_{ni/n}}_{=H_i} \underbrace{t^{ni}}_{=(t^n)^i} \qquad \text{(here, we have substituted } ni \text{ for } i \text{ in the sum)} \\
&= \sum_{i\geq 0} H_i (t^n)^i. \qquad (13.132.13)
\end{aligned}$$

[936] This is allowed because the element t^n of $\operatorname{NSym}[[t]]$ is central. (Generally, if R is a ring (possibly not commutative) and $Q \in R[[t]]$ is a power series, then every central element z of $R[[t]]$ can be substituted for t in Q as long as the constant coefficient of z is 0. The result of this substitution is denoted by $Q(z)$. The map $R[[t]] \to R[[t]]$ which sends every Q to $Q(z)$ (for a fixed z) is a ring homomorphism $R[[t]] \to R[[t]]$.)

Now,

$$\begin{aligned}(\mathbf{V}_n[[t]])\left(\underbrace{\xi(t)}_{=\log\left(\widetilde{H}(t)\right)}\right) &= (\mathbf{V}_n[[t]])\left(\log\left(\widetilde{H}(t)\right)\right) = \log\left(\underbrace{(\mathbf{V}_n[[t]])\left(\widetilde{H}(t)\right)}_{\substack{=\sum_{i\geq 0} H_i(t^n)^i \\ \text{(by (13.132.13))}}}\right) \\ &\qquad \left(\text{by (13.132.11), applied to } Q = \widetilde{H}(t)\right) \\ &= \log\left(\sum_{i\geq 0} H_i(t^n)^i\right) = \sum_{i\geq 1}\xi_i \underbrace{(t^n)^i}_{=t^{ni}} \qquad \text{(by (13.132.12))} \\ &= \sum_{i\geq 1}\xi_i t^{ni}. \end{aligned} \tag{13.132.14}$$

Comparing this with

$$(\mathbf{V}_n[[t]])\left(\underbrace{\xi(t)}_{=\sum_{i\geq 1}\xi_i t^i}\right) = (\mathbf{V}_n[[t]])\left(\sum_{i\geq 1}\xi_i t^i\right) = \sum_{i\geq 1}\mathbf{V}_n(\xi_i)\,t^i \qquad (\text{by the definition of } \mathbf{V}_n[[t]]),$$

we obtain

$$\sum_{i\geq 1}\mathbf{V}_n(\xi_i)\,t^i = \sum_{i\geq 1}\xi_i t^{ni}. \tag{13.132.15}$$

Now, let m be a positive integer. Comparing coefficients before t^m in the equality (13.132.15), we obtain

$$\mathbf{V}_n(\xi_m) = \begin{cases}\xi_{m/n}, & \text{if } n \mid m; \\ 0, & \text{if } n \nmid m\end{cases}.$$

This solves Exercise 5.4.14(b).

(f) Recall first that $(H_\alpha)_{\alpha\in\mathrm{Comp}}$ and $(M_\alpha)_{\alpha\in\mathrm{Comp}}$ are mutually dual bases with respect to the dual pairing $\mathrm{NSym}\otimes\mathrm{QSym}\xrightarrow{(\cdot,\cdot)}\mathbf{k}$. [937] Thus,

$$(H_\alpha, M_\beta) = \delta_{\alpha,\beta} \qquad \text{for any two compositions } \alpha \text{ and } \beta. \tag{13.132.16}$$

Let us introduce a notation: For every composition α and every positive integer s, let $\alpha\{s\}$ denote the ℓ-tuple $(s\alpha_1, s\alpha_2, \ldots, s\alpha_\ell)$, where α is written in the form $(\alpha_1,\alpha_2,\ldots,\alpha_\ell)$. Notice that if α is a composition and s is a positive integer, then $\alpha\{s\}$ is a composition again.

We have

$$\mathbf{F}_n M_\alpha = M_{\alpha\{n\}} \qquad \text{for every composition } \alpha. \tag{13.132.17}$$

[938].

[937] This follows from the definition of $(H_\alpha)_{\alpha\in\mathrm{Comp}}$.

[938] *Proof of (13.132.17):* Let α be a composition. Write α in the form $\alpha = (\alpha_1,\alpha_2,\ldots,\alpha_\ell)$. By the definition of M_α, we have $M_\alpha = \sum_{i_1<i_2<\cdots<i_\ell} x_{i_1}^{\alpha_1}x_{i_2}^{\alpha_2}\cdots x_{i_\ell}^{\alpha_\ell}$ (where the sum is over all ℓ-tuples $(i_1,i_2,\ldots,i_\ell)$ of positive integers satisfying $i_1<i_2<\cdots<i_\ell$).

On the other hand, the definition of $\alpha\{n\}$ yields $\alpha\{n\} = (n\alpha_1, n\alpha_2, \ldots, n\alpha_\ell)$ (since $\alpha = (\alpha_1,\alpha_2,\ldots,\alpha_\ell)$). Hence, the definition of $M_{\alpha\{n\}}$ yields

$$M_{\alpha\{n\}} = \sum_{i_1<i_2<\cdots<i_\ell} x_{i_1}^{n\alpha_1}x_{i_2}^{n\alpha_2}\cdots x_{i_\ell}^{n\alpha_\ell} \tag{13.132.18}$$

(where the sum is over all ℓ-tuples $(i_1,i_2,\ldots,i_\ell)$ of positive integers satisfying $i_1<i_2<\cdots<i_\ell$).

We need to prove that the maps $\mathbf{F}_n : \operatorname{QSym} \to \operatorname{QSym}$ and $\mathbf{V}_n : \operatorname{NSym} \to \operatorname{NSym}$ are adjoint with respect to the dual pairing $\operatorname{NSym} \otimes \operatorname{QSym} \xrightarrow{(\cdot,\cdot)} \mathbf{k}$. In other words, we need to prove that

$$(b, \mathbf{F}_n a) = (\mathbf{V}_n b, a) \qquad \text{for any } a \in \operatorname{QSym} \text{ and } b \in \operatorname{NSym}. \tag{13.132.19}$$

Proof of (13.132.19): Fix $a \in \operatorname{QSym}$ and $b \in \operatorname{NSym}$.

Recall that $(M_\alpha)_{\alpha \in \operatorname{Comp}}$ is a basis of the $\mathbf{k}$-module NSym. Hence, in proving (13.132.19), we can WLOG assume that a is an element of this basis $(M_\alpha)_{\alpha \in \operatorname{Comp}}$ (because the equality (13.132.19) is $\mathbf{k}$-linear in a). Assume this. Thus, a is an element of the basis $(M_\alpha)_{\alpha \in \operatorname{Comp}}$. In other words, there exists a $\beta \in \operatorname{Comp}$ such that $a = M_\beta$. Consider this β. We have $\mathbf{F}_n \underbrace{a}_{=M_\beta} = \mathbf{F}_n M_\beta = M_{\beta\{n\}}$ (by (13.132.17), applied to $\alpha = \beta$).

Recall that $(H_\alpha)_{\alpha \in \operatorname{Comp}}$ is a basis of the $\mathbf{k}$-module Λ. Hence, in proving (13.132.19), we can WLOG assume that b is an element of this basis $(H_\alpha)_{\alpha \in \operatorname{Comp}}$ (because the equality (13.132.19) is $\mathbf{k}$-linear in b). Assume this. Thus, b is an element of the basis $(H_\alpha)_{\alpha \in \operatorname{Comp}}$. In other words, there exists a $\gamma \in \operatorname{Comp}$ such that $b = H_\gamma$. Consider this γ. We have

$$\left(\underbrace{b}_{=H_\gamma}, \underbrace{\mathbf{F}_n a}_{=M_{\beta\{n\}}}\right) = \left(H_\gamma, M_{\beta\{n\}}\right) = \delta_{\gamma, \beta\{n\}} \tag{13.132.20}$$

(by (13.132.16), applied to γ and $\beta\{n\}$ instead of α and β).

Let us write the composition γ in the form $(\gamma_1, \gamma_2, \ldots, \gamma_\ell)$. Then, $\gamma = (\gamma_1, \gamma_2, \ldots, \gamma_\ell)$, so that $H_\gamma = H_{(\gamma_1, \gamma_2, \ldots, \gamma_\ell)} = H_{\gamma_1} H_{\gamma_2} \cdots H_{\gamma_\ell}$ (by (13.132.4), applied to $(\gamma_1, \gamma_2, \ldots, \gamma_\ell)$ instead of $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$).

Let us first assume that

$$(\text{not every } i \in \{1, 2, \ldots, \ell\} \text{ satisfies } n \mid \gamma_i). \tag{13.132.21}$$

Then, $\mathbf{V}_n \left(\underbrace{H_\gamma}_{=H_{(\gamma_1, \gamma_2, \ldots, \gamma_\ell)}} \right) = \mathbf{V}_n \left(H_{(\gamma_1, \gamma_2, \ldots, \gamma_\ell)} \right) = 0$ (by (13.132.5), applied to $(\gamma_1, \gamma_2, \ldots, \gamma_\ell)$ instead of $(\alpha_1, \alpha_2, \ldots, \alpha_\ell)$). Also, $\beta\{n\} \neq \gamma$ [939], so that $\delta_{\gamma, \beta\{n\}} = 0$. Thus, (13.132.20) becomes $(b, \mathbf{F}_n a) = \delta_{\gamma, \beta\{n\}} = 0$. Compared with $\left(\mathbf{V}_n \underbrace{b}_{=H_\gamma}, a \right) = \left(\underbrace{\mathbf{V}_n (H_\gamma)}_{=0}, a \right) = (0, a) = 0$ (since the dual pairing $\operatorname{NSym} \otimes \operatorname{QSym} \xrightarrow{(\cdot,\cdot)} \mathbf{k}$ is $\mathbf{k}$-bilinear), this yields $(b, \mathbf{F}_n a) = (\mathbf{V}_n b, a)$. Thus, (13.132.19) holds.

Now, let us forget that we assumed that (13.132.21) holds. We thus have proven (13.132.19) under the assumption that (13.132.21) holds. Hence, for the rest of our proof of (13.132.19), we can WLOG assume that (13.132.21) does not hold. Assume this.

We have assumed that (13.132.21) does not hold. In other words,

$$\text{every } i \in \{1, 2, \ldots, \ell\} \text{ satisfies } n \mid \gamma_i. \tag{13.132.22}$$

Thus, γ_i / n is a positive integer for every $i \in \{1, 2, \ldots, \ell\}$ (since γ_i is a positive integer for every $i \in \{1, 2, \ldots, \ell\}$). Thus, $(\gamma_1 / n, \gamma_2 / n, \ldots, \gamma_\ell / n)$ is a composition. Let us denote this composition by ζ. We have

Now, the definition of $\mathbf{F}_n$ yields

$$\begin{aligned} \mathbf{F}_n M_\alpha &= \underbrace{M_\alpha}_{= \sum_{i_1 < i_2 < \cdots < i_\ell} x_{i_1}^{\alpha_1} x_{i_2}^{\alpha_2} \cdots x_{i_\ell}^{\alpha_\ell}} (x_1^n, x_2^n, x_3^n, \ldots) = \left(\sum_{i_1 < i_2 < \cdots < i_\ell} x_{i_1}^{\alpha_1} x_{i_2}^{\alpha_2} \cdots x_{i_\ell}^{\alpha_\ell} \right) (x_1^n, x_2^n, x_3^n, \ldots) \\ &= \sum_{i_1 < i_2 < \cdots < i_\ell} x_{i_1}^{n\alpha_1} x_{i_2}^{n\alpha_2} \cdots x_{i_\ell}^{n\alpha_\ell} = M_{\alpha\{n\}} \qquad (\text{by } (13.132.18)). \end{aligned}$$

This proves (13.132.17).

[939] *Proof.* Assume the contrary. Thus, $\beta\{n\} = \gamma$. Let us write the composition β in the form $(\beta_1, \beta_2, \ldots, \beta_q)$. Then, $\beta\{n\} = (n\beta_1, n\beta_2, \ldots, n\beta_q)$ (by the definition of $\beta\{n\}$). Hence, $(\gamma_1, \gamma_2, \ldots, \gamma_\ell) = \gamma = \beta\{n\} = (n\beta_1, n\beta_2, \ldots, n\beta_q)$. As a consequence, $\ell = q$, so that $q = \ell$ and thus $(n\beta_1, n\beta_2, \ldots, n\beta_q) = (n\beta_1, n\beta_2, \ldots, n\beta_\ell)$. Hence, $(\gamma_1, \gamma_2, \ldots, \gamma_\ell) = (n\beta_1, n\beta_2, \ldots, n\beta_q) = (n\beta_1, n\beta_2, \ldots, n\beta_\ell)$. Consequently, every $i \in \{1, 2, \ldots, \ell\}$ satisfies $\gamma_i = n\beta_i$. Thus, every $i \in \{1, 2, \ldots, \ell\}$ satisfies $n \mid \gamma_i$. This contradicts (13.132.21). This contradiction proves that our assumption was wrong, qed.

$\zeta\{n\} = \gamma$ [940] and $\mathbf{V}_n(H_\gamma) = H_\zeta$ [941] and thus

$$\left(\mathbf{V}_n \underbrace{b}_{=H_\gamma}, \underbrace{a}_{=M_\beta}\right) = \left(\underbrace{\mathbf{V}_n(H_\gamma)}_{=H_\zeta}, M_\beta\right) = (H_\zeta, M_\beta) = \delta_{\zeta,\beta} \tag{13.132.23}$$

(by (13.132.16), applied to ζ instead of α).

Now, let us write the composition β in the form $(\beta_1, \beta_2, \ldots, \beta_s)$. Then, $\beta\{n\} = (n\beta_1, n\beta_2, \ldots, n\beta_s)$ (by the definition of $\beta\{n\}$).

Now, we have the following equivalence of assertions:

$$\begin{aligned}
&(\gamma = \beta\{n\}) \\
&\iff ((\gamma_1, \gamma_2, \ldots, \gamma_\ell) = (n\beta_1, n\beta_2, \ldots, n\beta_s)) \\
&\qquad (\text{since } \gamma = (\gamma_1, \gamma_2, \ldots, \gamma_\ell) \text{ and } \beta\{n\} = (n\beta_1, n\beta_2, \ldots, n\beta_s)) \\
&\iff \left(\text{we have } \ell = s \text{, and every } i \in \{1, 2, \ldots, \ell\} \text{ satisfies } \underbrace{\gamma_i = n\beta_i}_{\substack{\text{this is equivalent to} \\ \gamma_i/n=\beta_i}}\right) \\
&\iff (\text{we have } \ell = s \text{, and every } i \in \{1, 2, \ldots, \ell\} \text{ satisfies } \gamma_i/n = \beta_i) \\
&\iff ((\gamma_1/n, \gamma_2/n, \ldots, \gamma_\ell/n) = (\beta_1, \beta_2, \ldots, \beta_s)) \\
&\iff (\zeta = \beta) \qquad (\text{since } (\gamma_1/n, \gamma_2/n, \ldots, \gamma_\ell/n) = \zeta \text{ and } (\beta_1, \beta_2, \ldots, \beta_s) = \beta). \qquad (13.132.24)
\end{aligned}$$

This equivalence shows that $\delta_{\gamma,\beta\{n\}} = \delta_{\zeta,\beta}$. But (13.132.20) becomes

$$(b, \mathbf{F}_n a) = \delta_{\gamma,\beta\{n\}} = \delta_{\zeta,\beta} = (\mathbf{V}_n b, a) \qquad (\text{by (13.132.23)}).$$

Thus, (13.132.19) is proven. As we know, this completes the solution of Exercise 5.4.14(f).

(g) We know that $\pi : \mathrm{NSym} \to \Lambda$ is a $\mathbf{k}$-algebra homomorphism. Thus, $\pi(0) = 0$. Also, we know that

$$\pi(H_n) = h_n \qquad \text{for every positive integer } n. \tag{13.132.25}$$

Now, let n be a positive integer. The maps $\mathbf{v}_n \circ \pi$ and $\pi \circ \mathbf{V}_n$ are $\mathbf{k}$-algebra homomorphisms (since π and $\mathbf{v}_n$ are $\mathbf{k}$-algebra homomorphisms).

Let r be a positive integer. Applying (13.132.25) to r instead of n, we obtain $\pi(H_r) = h_r$.

If $n \mid r$, then r/n is a positive integer. Hence,

$$\text{if } n \mid r \text{, then } \pi\left(H_{r/n}\right) = h_{r/n}. \tag{13.132.26}$$

Now,

$$(\mathbf{v}_n \circ \pi)(H_r) = \mathbf{v}_n\left(\underbrace{\pi(H_r)}_{=h_r}\right) = \mathbf{v}_n(h_r) = \begin{cases} h_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases} \qquad (\text{by the definition of } \mathbf{v}_n).$$

[940] *Proof.* We have $\zeta = (\gamma_1/n, \gamma_2/n, \ldots, \gamma_\ell/n)$. Hence, the definition of $\zeta\{n\}$ yields $\zeta\{n\} = (n\gamma_1/n, n\gamma_2/n, \ldots, n\gamma_\ell/n) = (\gamma_1, \gamma_2, \ldots, \gamma_\ell) = \gamma$, qed.

[941] *Proof.* We have $\gamma = (\gamma_1, \gamma_2, \ldots, \gamma_\ell)$, so that

$$\begin{aligned}
\mathbf{V}_n(H_\gamma) &= \mathbf{V}_n\left(H_{(\gamma_1, \gamma_2, \ldots, \gamma_\ell)}\right) \\
&= H_{(\gamma_1/n, \gamma_2/n, \ldots, \gamma_\ell/n)} \qquad (\text{by (13.132.6), applied to } (\gamma_1, \gamma_2, \ldots, \gamma_\ell) \text{ instead of } (\alpha_1, \alpha_2, \ldots, \alpha_\ell)) \\
&= H_\zeta \qquad (\text{since } (\gamma_1/n, \gamma_2/n, \ldots, \gamma_\ell/n) = \zeta),
\end{aligned}$$

qed.

Compared with

$$(\pi \circ \mathbf{V}_n)(H_r) = \pi \left(\underbrace{\mathbf{V}_n(H_r)}_{\substack{= \begin{cases} H_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases} \\ \text{(by the definition of } \mathbf{V}_n)}} \right) = \pi \left(\begin{cases} H_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases} \right)$$

$$= \begin{cases} \pi\left(H_{r/n}\right), & \text{if } n \mid r; \\ \pi(0), & \text{if } n \nmid r \end{cases} = \begin{cases} \pi\left(H_{r/n}\right), & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases}$$

$$(\text{since } \pi(0) = 0 \text{ in the case when } n \nmid r)$$

$$= \begin{cases} h_{r/n}, & \text{if } n \mid r; \\ 0, & \text{if } n \nmid r \end{cases}$$

$$\left(\text{since } \pi\left(H_{r/n}\right) = h_{r/n} \text{ in the case when } n \mid r \text{ (according to (13.132.26))}\right),$$

this yields $(\mathbf{v}_n \circ \pi)(H_r) = (\pi \circ \mathbf{V}_n)(H_r)$.

Let us now forget that we fixed r. We thus have proven that

$$(\mathbf{v}_n \circ \pi)(H_r) = (\pi \circ \mathbf{V}_n)(H_r) \qquad \text{for every positive integer } r. \tag{13.132.27}$$

Now, recall that the family $(H_r)_{r\geq 1}$ generates the $\mathbf{k}$-algebra NSym (according to (13.132.2)). In other words, $(H_r)_{r\geq 1}$ is a generating set of the $\mathbf{k}$-algebra NSym. The two $\mathbf{k}$-algebra homomorphisms $\mathbf{v}_n \circ \pi$ and $\pi \circ \mathbf{V}_n$ are equal to each other on this generating set (according to (13.86.8)), and therefore must be identical (because if two $\mathbf{k}$-algebra homomorphisms from the same domain are equal to each other on a generating set of their domain, then these two homomorphisms must be identical). In other words, $\mathbf{v}_n \circ \pi = \pi \circ \mathbf{V}_n$. This completes the solution of Exercise 5.4.14(g).

(h) *Alternative solution of Exercise 2.9.10(f).* Let i denote the inclusion map $\Lambda \to \text{QSym}$. Then, Corollary 5.4.3 yields that the map π is adjoint to the map i with respect to the dual pairing $\text{NSym} \otimes \text{QSym} \xrightarrow{(\cdot,\cdot)} \mathbf{k}$. In other words,

$$(\pi(b), a) = (b, i(a)) \qquad \text{for every } b \in \text{NSym and } a \in \Lambda. \tag{13.132.28}$$

But Exercise 5.4.14(f) yields that the maps $\mathbf{F}_n : \text{QSym} \to \text{QSym}$ and $\mathbf{V}_n : \text{NSym} \to \text{NSym}$ are adjoint with respect to the dual pairing $\text{NSym} \otimes \text{QSym} \xrightarrow{(\cdot,\cdot)} \mathbf{k}$. In other words,

$$(b, \mathbf{F}_n a) = (\mathbf{V}_n b, a) \qquad \text{for any } a \in \text{QSym and } b \in \text{NSym}. \tag{13.132.29}$$

Now, fix a positive integer n. Let $a \in \Lambda$ and $b \in \Lambda$ be arbitrary. Then, $a \in \Lambda \subset \text{QSym}$. Exercise 5.4.13(f) yields $\mathbf{F}_n \mid_\Lambda = \mathbf{f}_n$. Thus, $\mathbf{f}_n = \mathbf{F}_n \mid_\Lambda$, so that $\mathbf{f}_n a = (\mathbf{F}_n \mid_\Lambda) a = \mathbf{F}_n a$.

On the other hand, the projection $\pi : \text{NSym} \to \Lambda$ is surjective. Hence, there exists some $b' \in \text{NSym}$ satisfying $b = \pi(b')$. Consider this b'.

Since the Hall inner product on Λ is symmetric, we have

$$(\mathbf{f}_n a, b) = \left(\underbrace{b}_{=\pi(b')}, \mathbf{f}_n a \right) = (\pi(b'), \mathbf{f}_n a) = \left(b', \underbrace{i(\mathbf{f}_n a)}_{\substack{= \mathbf{f}_n a \\ \text{(since } i \text{ is an inclusion map)}}} \right)$$

$$\text{(by (13.132.28), applied to } b' \text{ and } \mathbf{f}_n a \text{ instead of } b \text{ and } a)$$

$$= \left(b', \underbrace{\mathbf{f}_n a}_{= \mathbf{F}_n a} \right) = (b', \mathbf{F}_n a) = (\mathbf{V}_n b', a) \qquad \text{(by (13.132.29), applied to } b' \text{ instead of } b).$$

Comparing this with

$$\begin{aligned}
(a, \mathbf{v}_n b) &= \left(\mathbf{v}_n \underbrace{b}_{=\pi(b')}, a\right) \qquad \text{(since the Hall inner product on Λ is symmetric)} \\
&= \left(\underbrace{\mathbf{v}_n (\pi (b'))}_{=(\mathbf{v}_n \circ \pi)(b')}, a\right) = \left(\underbrace{\underbrace{(\mathbf{v}_n \circ \pi)}_{=\pi \circ \mathbf{V}_n}}_{\text{(by Exercise 5.4.14(g))}} (b'), a\right) = \left(\underbrace{(\pi \circ \mathbf{V}_n)(b')}_{=\pi(\mathbf{V}_n b')}, a\right) \\
&= (\pi (\mathbf{V}_n b'), a) = \left(\mathbf{V}_n b', \underbrace{i(a)}_{\substack{=a \\ \text{(since i is an inclusion map)}}}\right) \qquad \text{(by (13.132.28), applied to $\mathbf{V}_n b'$ instead of b)} \\
&= (\mathbf{V}_n b', a),
\end{aligned}$$

we obtain $(\mathbf{f}_n a, b) = (a, \mathbf{v}_n b)$.

Let us now forget that we fixed a and b. We have thus shown that $(\mathbf{f}_n a, b) = (a, \mathbf{v}_n b)$ for every $a \in \Lambda$ and $b \in \Lambda$. In other words, the maps $\mathbf{f}_n : \Lambda \to \Lambda$ and $\mathbf{v}_n : \Lambda \to \Lambda$ are adjoint with respect to the Hall inner product on Λ. Thus, Exercise 2.9.10(f) is solved once again. Hence, Exercise 5.4.14(h) is solved.

13.133. **Solution to Exercise 6.1.3.** *Solution to Exercise 6.1.3.*

Proof of Proposition 6.1.2. (a) This can be easily verified by hand, but here is a slicker way to see it: Let $\mathfrak{B}$ be the set $\mathfrak{A} \sqcup \{-\infty\}$, where $-\infty$ is a symbol. We define a total order on $\mathfrak{B}$ by extending the given total order on $\mathfrak{A}$ in such a way that every $a \in \mathfrak{A}$ satisfies $-\infty < a$. Consider the set $\mathfrak{B}^\infty$ of all infinite sequences of elements of $\mathfrak{B}$. Then, $\mathfrak{A}^*$ embeds into $\mathfrak{B}^\infty$ by identifying every word $(a_1, a_2, \ldots, a_n) \in \mathfrak{A}^*$ with the sequence $(a_1, a_2, \ldots, a_n, -\infty, -\infty, -\infty, \ldots) \in \mathfrak{B}^\infty$. It is easy to check that our order relation $\leq$ on $\mathfrak{A}^*$ thus becomes the restriction to $\mathfrak{A}^*$ of the smaller-or-equal relation of the lexicographic order on $\mathfrak{B}^\infty$. Consequently, it is a total order. Proposition 6.1.2(a) is thus proven.

(h) follows immediately from the definition of $\leq$.

(i) follows from common sense.

(k) Let $a \in \mathfrak{A}^*$ and $b \in \mathfrak{A}^*$ be such that b is nonempty. Then, a is a prefix of ab. Thus, $a \leq ab$ (by Proposition 6.1.2(h), applied to ab instead of b). But $a \neq ab$ [942]. Combined with $a \leq ab$, this yields $a < ab$. Proposition 6.1.2(k) is thus proven.

(b) Proposition 6.1.2(b) is an almost immediate consequence of the definition of $\leq$; its proof is thus left to the reader.

(c) Let $a, c, d \in \mathfrak{A}^*$ satisfy $ac \leq ad$. We have $ac = \left(a_1, a_2, \ldots, a_{\ell(a)}, c_1, c_2, \ldots, c_{\ell(c)}\right)$ and $ad = \left(a_1, a_2, \ldots, a_{\ell(a)}, d_1, d_2, \ldots, d_{\ell(d)}\right)$, and we have $ac \leq ad$. Due to the definition of $\leq$, this means that we must be in one of the following two situations:

- There exists an $i \in \{1, 2, \ldots, \min\{\ell(a) + \ell(c), \ell(a) + \ell(d)\}\}$ such that

$$\left((ac)_i < (ad)_i, \text{ and every } j \in \{1, 2, \ldots, i-1\} \text{ satisfies } (ac)_j = (ad)_j\right). \tag{13.133.1}$$

- The word ac is a prefix of ad.

If we are in the first of these two situations, then we clearly must have $i > \ell(a)$ (since otherwise, both $(ac)_i$ and $(ad)_i$ would equal a_i, and then $(ac)_i < (ad)_i$ would contradict $(ac)_i = a_i = (ad)_i$), and therefore i has the form $i = \ell(a) + i'$ for some $i' \in \{1, 2, \ldots, \min\{\ell(c), \ell(d)\}\}$. Then, (13.133.1) yields $(c_{i'} < d_{i'}$, and every $j \in \{1, 2, \ldots, i'-1\}$ satisfies $c_j = d_j)$. But this shows that $c \leq d$, and so we are done

[942] *Proof.* Assume the contrary. Then, $a = ab$. Hence, $a\varnothing = a = ab$. Cancelling a from this equality, we obtain $\varnothing = b$, so that the word b is empty. This contradicts the fact that b is nonempty. This contradiction proves that our assumption was wrong, qed.

in the first situation. In the second situation, we also have $c \leq d$ [943], and again we are done. Thus, Proposition 6.1.2(c) is proven.

(d) Let $a, b, c, d \in \mathfrak{A}^*$ satisfy $a \leq c$. We have $a = \left(a_1, a_2, \ldots, a_{\ell(a)}\right)$ and $c = \left(c_1, c_2, \ldots, c_{\ell(c)}\right)$, and we have $a \leq c$. Due to the definition of $\leq$, this means that we must be in one of the following two situations:

- There exists an $i \in \{1, 2, \ldots, \min\{\ell(a), \ell(c)\}\}$ such that
$$(a_i < c_i, \text{ and every } j \in \{1, 2, \ldots, i-1\} \text{ satisfies } a_j = c_j).$$
- The word a is a prefix of c.

The first of these situations entails $ab \leq cd$ (because every $k \in \{1, 2, \ldots, \min\{\ell(a), \ell(c)\}\}$ satisfies $(ab)_k = a_k$ and $(cd)_k = c_k$). Hence, in both situations, Proposition 6.1.2(d) is proven.

(e) Let $a, b, c, d \in \mathfrak{A}^*$ satisfy $ab \leq cd$. We have $a = \left(a_1, a_2, \ldots, a_{\ell(a)}\right)$, $b = \left(b_1, b_2, \ldots, b_{\ell(b)}\right)$, $c = \left(c_1, c_2, \ldots, c_{\ell(c)}\right)$ and $d = \left(d_1, d_2, \ldots, d_{\ell(d)}\right)$, and we have $ab \leq cd$. Due to the definition of $\leq$, this means that we must be in one of the following two situations:

- There exists an $i \in \{1, 2, \ldots, \min\{\ell(a) + \ell(b), \ell(c) + \ell(d)\}\}$ such that
$$\left((ab)_i < (cd)_i, \text{ and every } j \in \{1, 2, \ldots, i-1\} \text{ satisfies } (ab)_j = (cd)_j\right). \tag{13.133.2}$$
- The word ab is a prefix of cd.

It is easy to see that if we are in the second situation, then either we have $a \leq c$ or the word c is a prefix of a [944]. We are therefore done in the second situation. We can thus WLOG assume that we are in the first situation. Assume this. We thus have an $i \in \{1, 2, \ldots, \min\{\ell(a) + \ell(b), \ell(c) + \ell(d)\}\}$ satisfying (13.133.2). If $i \leq \min\{\ell(a), \ell(c)\}$, then this yields $a \leq c$ (because every $k \in \{1, 2, \ldots, \min\{\ell(a), \ell(c)\}\}$ satisfies $(ab)_k = a_k$ and $(cd)_k = c_k$), and we are done. If $i > \min\{\ell(a), \ell(c)\}$, then every $j \in \{1, 2, \ldots, \min\{\ell(a), \ell(c)\}\}$ satisfies $a_j = c_j$ (because every $j \in \{1, 2, \ldots, \min\{\ell(a), \ell(c)\}\}$ satisfies $j \in \{1, 2, \ldots, i-1\}$ and thus
$$\begin{aligned} a_j = (ab)_j &= (cd)_j \qquad \text{(by (13.133.2))} \\ &= c_j \end{aligned}$$
), and thus we conclude that either a is a prefix of c, or c is a prefix of a. Again, this means that we are done. Thus, Proposition 6.1.2(e) is proven.

(f) follows from (e), because if c is a prefix of a satisfying $\ell(a) \leq \ell(c)$, then $c = a$.

(g) Let $a, b, c \in \mathfrak{A}^*$ satisfy $a \leq b \leq ac$. Then, $b\varnothing = b \leq ac$. Hence, Proposition 6.1.2(e) (applied to $b, \varnothing, a, c$ instead of a, b, c, d) yields that either we have $b \leq a$ or the word a is a prefix of b. Since $b \leq a$ leads to $a = b$ (in view of $a \leq b$), we get in both of these cases that a is a prefix of b. This proves Proposition 6.1.2(g).

(j) Let $a, b, c \in \mathfrak{A}^*$ satisfy $a \leq b$ and $\ell(a) \geq \ell(b)$. Proposition 6.1.2(d) (applied to a, c, b and c) yields that either we have $ac \leq bc$ or the word a is a prefix of b. In the first of these two cases, we are obviously done. Hence, we WLOG assume that we are in the second of these two cases. Thus, the word a is a prefix of b. Since the word a is at least as long as b (in fact, $\ell(a) \geq \ell(b)$), this yields that $a = b$, so that $\underbrace{a}_{=b} c = bc \leq bc$.

This proves Proposition 6.1.2(j). □

[943] *Proof.* Let us consider the second situation. In this situation, the word ac is a prefix of ad. In other words, there exists a word z such that $ad = acz$. Consider this z. Cancelling a from the equality $ad = acz$, we obtain $d = cz$. Hence, the word c is a prefix of d. Thus, $c \leq d$, qed.

[944] *Proof.* Assume that we are in the second situation. Then, the word ab is a prefix of cd. In other words, there exists a word $z \in \mathfrak{A}^*$ such that $cd = abz$. Consider this z.

Now, a is a prefix of the word cd (since $cd = abz = a(bz)$). Also, c is a prefix of the word cd. Hence, a and c are two prefixes of the word cd. Thus, Proposition 6.1.2(i) (applied to c and cd instead of b and c) yields that either a is a prefix of c, or c is a prefix of a. Hence, either we have $a \leq c$ or c is a prefix of a (because if a is a prefix of c, then $a \leq c$). Qed.

13.134. **Solution to Exercise 6.1.7.** *Solution to Exercise 6.1.7.*

Alternative proof of Corollary 6.1.6. We shall prove Corollary 6.1.6 by strong induction on $\ell(u)+\ell(v)+\ell(w)$. That is, we fix an $N \in \mathbb{N}$, and we assume (as the induction hypothesis) that Corollary 6.1.6 holds in the case when $\ell(u)+\ell(v)+\ell(w) < N$. We then need to prove that Corollary 6.1.6 holds in the case when $\ell(u)+\ell(v)+\ell(w) = N$.

So let u, v and w be words satisfying $uv \geq vu$ and $vw \geq wv$ and $\ell(u)+\ell(v)+\ell(w) = N$. Assume that v is nonempty. We want to prove that $uw \geq wu$.

If $u = \varnothing$, then $uw \geq wu$ holds obviously (because if $u = \varnothing$, then $\underbrace{u}_{=\varnothing} w = w = w \underbrace{\varnothing}_{=u} = wu$). Hence, for the rest of this proof, we can WLOG assume that $u \neq \varnothing$. Assume this. For a similar reason, we WLOG assume that $w \neq \varnothing$. Recall also that v is nonempty; that is, $v \neq \varnothing$.

We have $\ell(u) > 0$ (since $u \neq \varnothing$) and $\ell(v) > 0$ (since $v \neq \varnothing$) and $\ell(w) > 0$ (since $w \neq \varnothing$).

Notice that

$$uvc \geq vuc \qquad \text{for every } c \in \mathfrak{A}^*. \tag{13.134.1}$$

[945] Also,

$$vwc \geq wvc \qquad \text{for every } c \in \mathfrak{A}^*. \tag{13.134.2}$$

[946]

Let us first assume that u is a prefix of w. Then, there exists a $w' \in \mathfrak{A}^*$ satisfying $w = uw'$ (since u is a prefix of w). Consider this w'. Applying (13.134.1) to $c = w'$, we obtain $uvw' \geq v \underbrace{uw'}_{=w} = vw \geq \underbrace{w}_{=uw'} v = uw'v$. That is, $uw'v \leq uvw'$. Hence, Proposition 6.1.2(c) (applied to $a = u$, $c = w'v$ and $d = vw'$) yields $w'v \leq vw'$, so that $vw' \geq w'v$. Furthermore, $\ell\left(\underbrace{w}_{=uw'}\right) = \underbrace{\ell(u)}_{>0} + \ell(w') > \ell(w')$, thus $\ell(w') < \ell(w)$ and therefore $\ell(u)+\ell(v)+\underbrace{\ell(w')}_{<\ell(w)} < \ell(u)+\ell(v)+\ell(w) = N$. Hence, Corollary 6.1.6 holds for w' instead of w (by the induction hypothesis). Consequently, we obtain $uw' \geq w'u$ (since $vw' \geq w'v$). Thus, $w'u \leq uw'$, so that $uw'u \leq uuw'$ (by Proposition 6.1.2(b), applied to $a = u$, $c = w'u$ and $d = uw'$). Thus, $uuw' \geq \underbrace{uw'}_{=w} u = wu$, so that $u \underbrace{w}_{=uw'} = uuw' \geq wu$.

Now, let us forget that we assumed that u is a prefix of w. We thus have proven that $uw \geq wu$ under the assumption that u is a prefix of w. Hence, for the rest of this proof of $uw \geq wu$, we can WLOG assume that

$$u \text{ is not a prefix of } w.$$

Assume this.

Let us next assume that v is a prefix of w. Then, there exists a $w' \in \mathfrak{A}^*$ satisfying $w = vw'$ (since v is a prefix of w). Consider this w'. We have $v \underbrace{vw'}_{=w} = vw \geq \underbrace{w}_{=vw'} v = vw'v$, thus $vw'v \leq vvw'$. Thus, Proposition 6.1.2(c) (applied to $a = v$, $c = w'v$ and $d = vw'$) yields $w'v \leq vw'$, so that $vw' \geq w'v$. Furthermore, $\ell\left(\underbrace{w}_{=vw'}\right) = \underbrace{\ell(v)}_{>0} + \ell(w') > \ell(w')$, thus $\ell(w') < \ell(w)$ and therefore $\ell(u)+\ell(v)+\underbrace{\ell(w')}_{<\ell(w)} < \ell(u)+\ell(v)+\ell(w) = N$. Hence, Corollary 6.1.6 holds for w' instead of w (by the induction hypothesis). Consequently, we obtain $uw' \geq w'u$ (since $vw' \geq w'v$). Thus, $w'u \leq uw'$, so that $vw'u \leq vuw'$ (by

[945] *Proof of (13.134.1):* Let $c \in \mathfrak{A}^*$. We have $uv \geq vu$ and thus $vu \leq uv$. Also, $\ell(vu) = \ell(v)+\ell(u) = \ell(u)+\ell(v) = \ell(uv)$. Hence, Proposition 6.1.2(j) (applied to $a = vu$ and $b = uv$) yields $vuc \leq uvc$, so that $uvc \geq vuc$. This proves (13.134.1).

[946] *Proof of (13.134.2):* Let $c \in \mathfrak{A}^*$. We have $vw \geq wv$ and thus $wv \leq vw$. Also, $\ell(wv) = \ell(w)+\ell(v) = \ell(v)+\ell(w) = \ell(vw)$. Hence, Proposition 6.1.2(j) (applied to $a = wv$ and $b = vw$) yields $wvc \leq vwc$, so that $vwc \geq wvc$. This proves (13.134.2).

Proposition 6.1.2(b), applied to $a = v$, $c = w'u$ and $d = uw'$). Thus, $vuw' \geq \underbrace{vw'}_{=w} u = wu$. But (13.134.1) (applied to $c = w'$) yields $uvw' \geq vuw' \geq wu$, thus $u \underbrace{w}_{=vw'} = uvw' \geq wu$.

Now, let us forget that we assumed that v is a prefix of w. We thus have proven that $uw \geq wu$ under the assumption that v is a prefix of w. Hence, for the rest of this proof of $uw \geq wu$, we can WLOG assume that

$$v \text{ is not a prefix of } w.$$

Assume this.

We have $vw \geq wv$, thus $wv \leq vw$. Hence, Proposition 6.1.2(e) (applied to $a = w$, $b = v$, $c = v$ and $d = w$) yields that either we have $w \leq v$ or the word v is a prefix of w. Since the word v is not a prefix of w, this yields that we have $w \leq v$. Thus,

$$v \geq w.$$

Let us next assume that w is a prefix of u. Then, there exists a $u' \in \mathfrak{A}^*$ satisfying $u = wu'$ (since w is a prefix of u). Consider this u'. We have $uv \geq vu$ and thus $\underbrace{wu'}_{=u} v = uv \geq v \underbrace{u}_{=wu'} = vwu' \geq wvu'$ (by (13.134.2), applied to $c = u'$). In other words, $wvu' \leq wu'v$. Hence, Proposition 6.1.2(c) (applied to $a = w$, $c = vu'$ and $d = u'v$) yields $vu' \leq u'v$, so that $u'v \geq vu'$. Furthermore, $\ell \left(\underbrace{u}_{=wu'} \right) = \underbrace{\ell(w)}_{>0} + \ell(u') > \ell(u')$, thus $\ell(u') < \ell(u)$ and therefore $\underbrace{\ell(u')}_{<\ell(u)} + \ell(v) + \ell(w) < \ell(u) + \ell(v) + \ell(w) = N$. Hence, Corollary 6.1.6 holds for u' instead of u (by the induction hypothesis). Consequently, we obtain $u'w \geq wu'$ (since $u'v \geq vu'$). Thus, $wu' \leq u'w$, so that $wwu' \leq wu'w$ (by Proposition 6.1.2(b), applied to $a = w$, $c = wu'$ and $d = u'w$). Thus, $wu'w \geq w \underbrace{wu'}_{=u} = wu$, so that $\underbrace{u}_{=wu'} w = wu'w \geq wu$.

Now, let us forget that we assumed that w is a prefix of u. We thus have proven that $uw \geq wu$ under the assumption that w is a prefix of u. Hence, for the rest of this proof of $uw \geq wu$, we can WLOG assume that

$$w \text{ is not a prefix of } u.$$

Assume this.

Let us now assume that u is a prefix of v. Then, there exists a $v' \in \mathfrak{A}^*$ satisfying $v = uv'$ (since u is a prefix of v). Consider this v'. We have $uv' = v \geq w = w\varnothing$. Hence, $w\varnothing \leq uv'$. Thus, Proposition 6.1.2(e) (applied to $a = w$, $b = \varnothing$, $c = u$ and $d = v'$) yields that either we have $w \leq u$ or the word u is a prefix of w. Since the word u is not a prefix of w, we can conclude from this that $w \leq u$. Thus, Proposition 6.1.2(d) (applied to $a = w$, $b = u$, $c = u$ and $d = w$) shows that either we have $wu \leq uw$ or the word w is a prefix of u. Since the word w is not a prefix of u, this yields that $wu \leq uw$, so that $uw \geq wu$.

Now, let us forget that we assumed that u is a prefix of v. We thus have proven that $uw \geq wu$ under the assumption that u is a prefix of v. Hence, for the rest of this proof of $uw \geq wu$, we can WLOG assume that

$$u \text{ is not a prefix of } v.$$

Assume this.

We have $uv \geq vu$, thus $vu \leq uv$. Hence, Proposition 6.1.2(e) (applied to $a = v$, $b = u$, $c = u$ and $d = v$) yields that either we have $v \leq u$ or the word u is a prefix of v. Since the word u is not a prefix of v, this yields that we have $v \leq u$. Thus, $u \geq v$. Combined with $v \geq w$, this yields $u \geq w$, so that $w \leq u$. Thus, Proposition 6.1.2(d) (applied to $a = w$, $b = u$, $c = u$ and $d = w$) shows that either we have $wu \leq uw$ or the word w is a prefix of u. Since the word w is not a prefix of u, this yields that $wu \leq uw$, so that $uw \geq wu$. Our proof of $uw \geq wu$ is thus complete.

Now, let us forget that we fixed u, v and w. We have thus shown that if u, v and w are words satisfying $uv \geq vu$ and $vw \geq wv$ and $\ell(u) + \ell(v) + \ell(w) = N$, and if v is nonempty, then $uw \geq wu$. In other words, Corollary 6.1.6 holds in the case when $\ell(u) + \ell(v) + \ell(w) = N$. This completes the induction step. We thus have proven Corollary 6.1.6 (again). □

13.135. **Solution to Exercise 6.1.9.** *Solution to Exercise 6.1.9.* If the word u is empty, then Exercise 6.1.9 is easy to solve[947]. Hence, for the rest of this solution, we can WLOG assume that the word u is nonempty. Assume this. The word u^n is nonempty (since u is nonempty and n is a positive integer). In other words, the word v^m is nonempty (since $u^n = v^m$). Thus, v is nonempty.

We have $u \underbrace{v^m}_{=u^n} = uu^n = u^{n+1} = \underbrace{u^n}_{=v^m} u = v^m u$ and $v^m v = v^{m+1} = vv^m$. Hence, Corollary 6.1.6 (applied to u, v^m and v instead of u, v and w) yields $uv \geq vu$ (since v^m is nonempty).

But we also have $vv^m = v^m v$ (since $v^m v = vv^m$) and $v^m u = uv^m$ (since $uv^m = v^m u$). Thus, Corollary 6.1.6 (applied to v, v^m and u instead of u, v and w) yields $vu \geq uv$ (since v^m is nonempty). Combined with $uv \geq vu$, this yields $uv = vu$. Hence, Proposition 6.1.4 yields that there exist a $t \in \mathfrak{A}^*$ and two nonnegative integers i and j such that $u = t^i$ and $v = t^j$ [948]. Consider this t and these i and j. We have $i \neq 0$ (since $t^i = u$ is nonempty), so that i is a positive integer. Also, $j \neq 0$ (since $t^j = v$ is nonempty), and therefore j is a positive integer.

We have thus shown that there exists a word t and positive integers i and j such that $u = t^i$ and $v = t^j$. Exercise 6.1.9 is thus solved.

13.136. **Solution to Exercise 6.1.10.** *Solution to Exercise 6.1.10.* We WLOG assume that u is nonempty (because otherwise, both $uv \geq vu$ and $u^n v^m \geq v^m u^n$ hold for trivial reasons). Similarly, we WLOG assume that v is nonempty.

The exercise asks us to prove the equivalence $(uv \geq vu) \Longleftrightarrow (u^n v^m \geq v^m u^n)$. We shall verify its $\Longrightarrow$ and $\Longleftarrow$ parts separately:

$\Longrightarrow$: Assume that $uv \geq vu$ holds. Then, Corollary 6.1.6 (applied to $w = v^m$) yields $uv^m \geq v^m u$ (since $vv^m = v^{m+1} = v^m v$). Thus, Corollary 6.1.6 (applied to u^n, u and v^m instead of u, v and w) yields $u^n v^m \geq v^m u^n$ (since $u^n u = u^{n+1} = uu^n$). This proves the $\Longrightarrow$ part of the equivalence $(uv \geq vu) \Longleftrightarrow (u^n v^m \geq v^m u^n)$.

$\Longleftarrow$: Assume that $u^n v^m \geq v^m u^n$ holds. Then, Corollary 6.1.6 (applied to u, u^n and v^m instead of u, v and w) yields $uv^m \geq v^m u$ (since $uu^n = u^{n+1} = u^n u$, and since the word u^n is nonempty[949]). Hence, Corollary 6.1.6 (applied to u, v^m and v instead of u, v and w) yields $uv \geq vu$ (since $v^m v = v^{m+1} = vv^m$, and since the word v^m is nonempty[950]). This proves the $\Longleftarrow$ part of the equivalence $(uv \geq vu) \Longleftrightarrow (u^n v^m \geq v^m u^n)$.

Thus, both the $\Longrightarrow$ and the $\Longleftarrow$ part of the equivalence $(uv \geq vu) \Longleftrightarrow (u^n v^m \geq v^m u^n)$ are proven, and Exercise 6.1.10 is solved.

13.137. **Solution to Exercise 6.1.11.** *Solution to Exercise 6.1.11.*

Notice that $\ell(u^n) = n\ell(u) = m\ell(v) = \ell(v^m)$ (since $\ell(v^m) = m\ell(v)$), thus $\ell(v^m) = \ell(u^n)$. Now, we have the following two logical implications:

$$(u^n v^m \geq v^m u^n) \Longrightarrow (u^n \geq v^m)$$

[951] and

$$(u^n \geq v^m) \Longrightarrow (u^n v^m \geq v^m u^n)$$

[947] *Proof.* Assume that the word u is empty. Thus, $u = \varnothing$. Hence, $u^n = \varnothing^n = \varnothing$, so that $\varnothing = u^n = v^m$ and thus $v^m = \varnothing$. Consequently, $v = \varnothing$ (since m is positive). Thus, there exists a word t and positive integers i and j such that $u = t^i$ and $v = t^j$ (namely, we can take $t = \varnothing$ and $i = 1$ and $j = 1$). In other words, Exercise 6.1.9 is solved.

[948] The i and j here are the variables called n and m in Proposition 6.1.4.

[949] because u is nonempty and n is positive

[950] because v is nonempty and m is positive

[951] *Proof.* Assume that $u^n v^m \geq v^m u^n$. We need to prove that $u^n \geq v^m$.

We have $v^m u^n \leq u^n v^m$ (since $u^n v^m \geq v^m u^n$) and $\ell(v^m) \leq \ell(u^n)$ (since $\ell(v^m) = \ell(u^n)$). Hence, $v^m \leq u^n$ (by Proposition 6.1.2(f), applied to $a = v^m$, $b = u^n$, $c = u^n$ and $d = v^m$). Thus, $u^n \geq v^m$, qed.

[952]. Combining these two implications, we obtain the equivalence $(u^n v^m \geq v^m u^n) \iff (u^n \geq v^m)$. But Exercise 6.1.10 shows that we have the equivalence $(uv \geq vu) \iff (u^n v^m \geq v^m u^n)$. Altogether, we thus obtain the following chain of equivalences:

$$(uv \geq vu) \iff (u^n v^m \geq v^m u^n) \iff (u^n \geq v^m) .$$

This solves Exercise 6.1.11.

13.138. **Solution to Exercise 6.1.12.** *Solution to Exercise 6.1.12.* If w is a nonempty word, then let us denote by $\operatorname{rad}(w)$ the shortest word p such that w is a power of p. (This is clearly well-defined because w is a power of itself, and because for every given integer λ there exists at most one word v of length λ such that w is a power of v.)

Every nonempty word w and every positive integer n satisfy

$$\operatorname{rad}(w^n) = \operatorname{rad}(w) . \qquad (13.138.1)$$

Proof of (13.138.1): Let w be a nonempty word, and let n be a positive integer. Let $q = \operatorname{rad}(w^n)$. Thus, q is the shortest word p such that w^n is a power of p. Consequently, w^n is a power of q, so that there exists a positive integer N such that $w^n = q^N$. Consider this N.

The word w^n is nonempty (since w is nonempty and n is positive). That is, the word q^N is nonempty (since $w^n = q^N$). Hence, the word q is nonempty, so that $\ell(q)$ is nonzero.

Exercise 6.1.9 (applied to w, q, n and N instead of u, v, n and m) yields that there exists a word t and positive integers i and j such that $w = t^i$ and $q = t^j$. Consider these t, i and j. We have $q = t^j$ and thus $q^N = (t^j)^N = t^{jN}$, so that $t^{jN} = q^N = w^n$. Hence, w^n is a power of t. The word t thus cannot be shorter than q (since q is the shortest word p such that w^n is a power of p). Consequently, $j = 1$ (because otherwise, t would be shorter than $t^j = q$). Hence, $q = t^j = t$ (since $j = 1$) and $w = t^i = q^i$ (since $t = q$). Thus, w is a power of q. Consequently, $\ell(q) \geq \ell(\operatorname{rad}(w))$ (since $\operatorname{rad}(w)$ is the shortest word p such that w is a power of p).

On the other hand, $\operatorname{rad}(w)$ is the shortest word p such that w is a power of p. Thus, w is a power of $\operatorname{rad}(w)$. That is, there exists a $P \in \mathbb{N}$ such that $w = (\operatorname{rad}(w))^P$. Consider this P. We have $P > 0$ (since $(\operatorname{rad}(w))^P = w$ is nonempty), so that $Pn > 0$ (since $n > 0$). Also, taking both sides of the equality $w = (\operatorname{rad}(w))^P$ to the n-th power, we obtain $w^n = \left((\operatorname{rad}(w))^P\right)^n = (\operatorname{rad}(w))^{Pn}$, so that w^n is a power of $\operatorname{rad}(w)$.

Recall that q is the shortest word p such that w^n is a power of p. Since w^n is a power of $\operatorname{rad}(w)$, this yields that $\ell(\operatorname{rad}(w)) \geq \ell(q)$. Combined with $\ell(q) \geq \ell(\operatorname{rad}(w))$, this yields $\ell(\operatorname{rad}(w)) = \ell(q)$. Now,

$$\ell\left(\underbrace{w^n}_{=(\operatorname{rad}(w))^{Pn}}\right) = \ell\left((\operatorname{rad}(w))^{Pn}\right) = Pn \cdot \underbrace{\ell(\operatorname{rad}(w))}_{=\ell(q)} = Pn \cdot \ell(q) .$$

Compared with $\ell\left(\underbrace{w^n}_{=q^N}\right) = \ell\left(q^N\right) = N \cdot \ell(q)$, this yields $Pn \cdot \ell(q) = N \cdot \ell(q)$. Division by $\ell(q)$ (which is nonzero) yields $Pn = N$. Thus,

$$q^{Pn} = q^N = w^n = (\operatorname{rad}(w))^{Pn} .$$

[952] *Proof.* Assume that $u^n \geq v^m$. We need to prove that $u^n v^m \geq v^m u^n$.

If $v^m u^n \leq u^n v^m$, then $u^n v^m \geq v^m u^n$ is obviously true. Hence, for the rest of this proof of $u^n v^m \geq v^m u^n$, we can WLOG assume that we don't have $v^m u^n \leq u^n v^m$. Assume this.

We have $v^m \leq u^n$ (since $u^n \geq v^m$). Hence, Proposition 6.1.2(d) (applied to $a = v^m$, $b = u^n$, $c = u^n$ and $d = v^m$) yields that either we have $v^m u^n \leq u^n v^m$ or the word v^m is a prefix of u^n. Since we don't have $v^m u^n \leq u^n v^m$, we therefore conclude that the word v^m is a prefix of u^n. In other words, there exists a $t \in \mathfrak{A}^*$ such that $u^n = v^m t$. Consider this t.

We have $\ell(v^m) = \ell\left(\underbrace{u^n}_{=v^m t}\right) = \ell(v^m t) = \ell(v^m) + \ell(t)$, thus $0 = \ell(t)$. Hence, the word t is empty, i.e., we have $t = \varnothing$. Thus, $u^n = v^m \underbrace{t}_{=\varnothing} = v^m$, so that $\underbrace{u^n}_{=v^m} v^m = v^m \underbrace{v^m}_{=u^n} = v^m u^n \geq v^m u^n$, qed.

Since taking the Pn-th root of a word is unambiguous (when said root exists)[953], this yields $q = \operatorname{rad}(w)$. Because of $q = \operatorname{rad}(w^n)$, this rewrites as $\operatorname{rad}(w^n) = \operatorname{rad}(w)$. This proves (13.138.1).

Next, we notice that

$$\text{any two nonempty words } u \text{ and } v \text{ satisfying } uv = vu \text{ satisfy } \operatorname{rad}(u) = \operatorname{rad}(v). \qquad (13.138.2)$$

Proof of (13.138.2): Let u and v be two nonempty words satisfying $uv = vu$. Proposition 6.1.4 yields that there exist a $t \in \mathfrak{A}^*$ and two nonnegative integers n and m such that $u = t^n$ and $v = t^m$. Consider this t and these n and m. Since $u = t^n$, we have $\operatorname{rad}(u) = \operatorname{rad}(t^n) = \operatorname{rad}(t)$ (by (13.138.1), applied to t instead of w). Similarly, $\operatorname{rad}(v) = \operatorname{rad}(t)$. Thus, $\operatorname{rad}(u) = \operatorname{rad}(t) = \operatorname{rad}(v)$, and this proves (13.138.2).

Now, we can finally solve the exercise. Let us show that

$$u_1u_i \geq u_iu_1 \qquad \text{for every } i \in \{1, 2, \ldots, k\}. \qquad (13.138.3)$$

Indeed, (13.138.3) can be proven by induction over i: The *base case* ($i = 1$) is obvious, whereas the *induction step* (proving $u_1u_{i+1} \geq u_{i+1}u_1$ using $u_1u_i \geq u_iu_1$) results from applying Corollary 6.1.6 to $u = u_1$, $v = u_i$ and $w = u_{i+1}$ (because we have $u_iu_{i+1} \geq u_{i+1}u_i$ by assumption). We thus have shown (13.138.3).

Now, we can apply (13.138.3) to $i = k$, and obtain $u_1u_k \geq u_ku_1$. But on the other hand, we can apply $u_iu_{i+1} \geq u_{i+1}u_i$ to $i = k$, and obtain $u_ku_{k+1} \geq u_{k+1}u_k$. Since $u_{k+1} = u_1$, this rewrites as $u_ku_1 \geq u_1u_k$. Contrasting this with $u_1u_k \geq u_ku_1$, we obtain $u_1u_k = u_ku_1$. Hence, (13.138.2) (applied to $u = u_1$ and $v = u_k$) yields $\operatorname{rad}(u_1) = \operatorname{rad}(u_k)$. Similarly, we can show that $\operatorname{rad}(u_i) = \operatorname{rad}(u_{i-1})$ for every $i \in \{1, 2, \ldots, k\}$, where u_0 means u_k (in fact, our situation is invariant under cyclically shifting the k-tuple $(u_1, u_2, \ldots, u_k)$). Hence, $\operatorname{rad}(u_k) = \operatorname{rad}(u_{k-1}) = \cdots = \operatorname{rad}(u_1)$. Denote this common value $\operatorname{rad}(u_k) = \operatorname{rad}(u_{k-1}) = \cdots = \operatorname{rad}(u_1)$ by t. Then, for every $i \in \{1, 2, \ldots, k\}$, we have $t = \operatorname{rad}(u_i)$, whence u_i is a power of t (because $\operatorname{rad}(u_i)$ is defined as the shortest word p such that u_i is a power of p). This solves Exercise 6.1.12.

13.139. **Solution to Exercise 6.1.21.** *Solution to Exercise 6.1.21.* (a) We shall solve Exercise 6.1.21(a) by strong induction on $\ell(u) + \ell(v)$.

Induction step: Let $N \in \mathbb{N}$. Assume that Exercise 6.1.21(a) is already solved in the case when $\ell(u)+\ell(v) < N$. We now need to solve Exercise 6.1.21(a) in the case when $\ell(u) + \ell(v) = N$.

We have assumed that Exercise 6.1.21(a) is already solved in the case when $\ell(u) + \ell(v) < N$. In other words, we know that

$$\left(\begin{array}{c}\text{if } u \in \mathfrak{A}^* \text{ and } v \in \mathfrak{A}^* \text{ are two words satisfying } uv < vu \text{ and } \ell(u) + \ell(v) < N, \\ \text{then there exists a nonempty suffix } s \text{ of } u \text{ satisfying } sv < v\end{array}\right). \qquad (13.139.1)$$

So let $u \in \mathfrak{A}^*$ and $v \in \mathfrak{A}^*$ be two words satisfying $uv < vu$ and $\ell(u) + \ell(v) = N$. We are going to prove that there exists a nonempty suffix s of u satisfying $sv < v$.

Indeed, let us assume the contrary. Thus, there exists no nonempty suffix s of u satisfying $sv < v$. Hence,

$$\text{whenever } s \text{ is a nonempty suffix of } u, \text{ we do } \textbf{not} \text{ have } sv < v. \qquad (13.139.2)$$

We have $u \neq \varnothing$ (since otherwise, we would have $u = \varnothing$ and thus $\underbrace{u}_{=\varnothing} v = v = v \underbrace{\varnothing}_{=u} = vu$, which would contradict $uv < vu$). In other words, the word u is nonempty. Similarly, the word v is nonempty. We have $\ell(u) > 0$ (since u is nonempty) and $\ell(v) > 0$ (since v is nonempty).

We have $\ell(uv) = \underbrace{\ell(u)}_{>0} + \ell(v) > \ell(v)$, thus $\ell(uv) \neq \ell(v)$, hence $uv \neq v$.

Since u is a nonempty suffix of u, we can apply (13.139.2) to $s = u$. As a result, we conclude that we do **not** have $uv < v$. Hence, we do **not** have $uv \leq v$ [954]. In other words, we do **not** have $uv \leq v\varnothing$ (since $v\varnothing = v$).

But $uv\varnothing = uv < vu$. Thus, Proposition 6.1.2(e) (applied to $a = uv$, $b = \varnothing$, $c = v$ and $d = u$) yields that either we have $uv \leq v$ or the word v is a prefix of uv. Since we do not have $uv \leq v$, we can therefore

[953] because $Pn > 0$

[954] *Proof.* Assume the contrary. Then, $uv \leq v$. Since $uv \neq v$, this yields $uv < v$. This contradicts the fact that we do **not** have $uv < v$. This contradiction proves that our assumption was wrong, qed.

conclude that the word v is a prefix of the word uv. In other words, there exists a word $g \in \mathfrak{A}^*$ such that $uv = vg$. Consider this g.

Since u is a prefix of uv, we have $u \leq uv < vu$. Thus, $u\varnothing = u < vu$. Hence, Proposition 6.1.2(e) (applied to $a = u$, $b = \varnothing$, $c = v$ and $d = u$) yields that either we have $u \leq v$ or the word v is a prefix of u. In other words, we are in one of the following two cases:

Case 1: We have $u \leq v$.

Case 2: The word v is a prefix of u.

Let us consider Case 1 first. In this case, we have $u \leq v$. Thus, Proposition 6.1.2(d) (applied to $a = u$, $b = v$, $c = v$ and $d = \varnothing$) yields that either we have $uv \leq v\varnothing$ or the word u is a prefix of v. Since we do not have $uv \leq v\varnothing$, this yields that the word u is a prefix of v. In other words, there exists a word $q \in \mathfrak{A}^*$ such that $v = uq$. Consider this q. We have $\ell\left(\underbrace{v}_{=uq}\right) = \ell(uq) = \underbrace{\ell(u)}_{>0} + \ell(q) > \ell(q)$, so that $\ell(q) < \ell(v)$. Also, $u\underbrace{uq}_{=v} = uv < \underbrace{v}_{=uq}u = uqu$. Hence, Proposition 6.1.2(c) (applied to $a = u$, $c = uq$ and $d = qu$) yields that $uq \leq qu$. Hence, $uq < qu$ [955]. Since $\ell(u) + \underbrace{\ell(q)}_{<\ell(v)} < \ell(u) + \ell(v) = N$, we can therefore apply (13.139.1) to q instead of v. As a result, we obtain that there exists a nonempty suffix s of u satisfying $sq < q$. Let us denote this s by t. Thus, t is a nonempty suffix of u satisfying $tq < q$. Thus, Proposition 6.1.2(j) (applied to $a = tq$, $b = q$ and $c = g$) yields that $tqg \leq qg$ (because $\ell(tq) = \underbrace{\ell(t)}_{\substack{>0 \\ \text{(since } t \text{ is nonempty)}}} + \ell(q) > \ell(q)$).

But $\underbrace{uq}_{=v}g = vg = uv$ (since $uv = vg$). Cancelling u from this equality, we obtain $qg = v$. Hence, $t\underbrace{v}_{=qg} = tqg \leq qg = v$. But we have $\ell(tv) = \underbrace{\ell(t)}_{\substack{>0 \\ \text{(since } t \text{ is nonempty)}}} + \ell(v) > \ell(v)$, thus $\ell(tv) \neq \ell(v)$, hence $tv \neq v$. Combined with $tv \leq v$, this yields $tv < v$.

On the other hand, t is a nonempty suffix of u. Hence, (13.139.2) (applied to $s = t$) yields that we do **not** have $tv < v$. This contradicts the fact that $tv < v$. Hence, we have obtained a contradiction in Case 1.

Let us now consider Case 2. In this case, the word v is a prefix of u. Hence, there exists a word $r \in \mathfrak{A}^*$ satisfying $u = vr$. Consider this r. Clearly, r is a suffix of u (since $u = vr$).

We have $\underbrace{vr}_{=u}v = uv < v\underbrace{u}_{=vr} = vvr$. Thus, Proposition 6.1.2(c) (applied to $a = v$, $c = rv$ and $d = vr$) yields $rv \leq vr$. Hence, $rv < vr$ [956]. Also, $\ell\left(\underbrace{u}_{=vr}\right) = \ell(vr) = \underbrace{\ell(v)}_{>0} + \ell(r) > \ell(r)$, so that $\ell(r) < \ell(u)$ and thus $\underbrace{\ell(r)}_{<\ell(u)} + \ell(v) < \ell(u) + \ell(v) = N$. Therefore, (13.139.1) can be applied to r instead of u. As a result, we obtain that there exists a nonempty suffix s of r satisfying $sv < v$. Let us denote this by t. Thus, t is a nonempty suffix of r satisfying $tv < v$.

We know that t is a suffix of the word r, which (in turn) is a suffix of u. Hence, t is a suffix of u. Thus, (13.139.2) (applied to $s = t$) yields that we do **not** have $tv < v$. This contradicts the fact that $tv < v$. Hence, we have obtained a contradiction in Case 2.

We thus have obtained a contradiction in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this yields that we always have a contradiction. Therefore, our assumption was wrong. So we have proven that there exists a nonempty suffix s of u satisfying $sv < v$.

[955] *Proof.* If we had $uq = qu$, then we would have $u\underbrace{uq}_{=qu} = uqu$, which would contradict $uuq < uqu$. Hence, we cannot have $uq = qu$. Thus, we have $uq \neq qu$. Combined with $uq \leq qu$, this yields $uq < qu$, qed.

[956] *Proof.* If we had $rv = vr$, then we would have $v\underbrace{rv}_{=vr} = vvr$, which would contradict $vrv < vvr$. Hence, we cannot have $rv = vr$. Thus, we have $rv \neq vr$. Combined with $rv \leq vr$, this yields $rv < vr$, qed.

Now, let us forget that we fixed u and v. We thus have proven that if $u \in \mathfrak{A}^*$ and $v \in \mathfrak{A}^*$ are two words satisfying $uv < vu$ and $\ell(u) + \ell(v) = N$, then there exists a nonempty suffix s of u satisfying $sv < v$. In other words, we have solved Exercise 6.1.21(a) in the case when $\ell(u) + \ell(v) = N$. This completes the induction step. Hence, Exercise 6.1.21(a) is solved by strong induction.

(b)

Alternative proof of Theorem 6.1.20. Proof of the implication $\mathcal{A} \Longrightarrow \mathcal{B}$: Assume that Assertion $\mathcal{A}$ holds. Thus, the word w is Lyndon. Hence, every nonempty proper suffix of w is $> w$ (by the definition of a Lyndon word). Now, let u and v be any nonempty words satisfying $w = uv$. Then, v is a nonempty proper suffix of w, and therefore $> w$ (since every nonempty proper suffix of w is $> w$). That is, we have $v > w$.

Now, let us forget that we fixed u and v. We thus have shown that any nonempty words u and v satisfying $w = uv$ satisfy $v > w$. In other words, Assertion $\mathcal{B}$ holds. Thus, the implication $\mathcal{A} \Longrightarrow \mathcal{B}$ is proven.

Proof of the implication $\mathcal{A} \Longrightarrow \mathcal{C}$: This implication follows from Proposition 6.1.14(b).

Proof of the implication $\mathcal{A} \Longrightarrow \mathcal{D}$: This implication follows from Proposition 6.1.14(c).

Proof of the implication $\mathcal{B} \Longrightarrow \mathcal{A}$: Assume that Assertion $\mathcal{B}$ holds. Let v be a nonempty proper suffix of w. Then, there exists a nonempty $u \in \mathfrak{A}^*$ satisfying $w = uv$ (since v is a proper suffix of w). Consider this u. Assertion $\mathcal{B}$ yields $v > w$.

Now, let us forget that we fixed v. We thus have shown that every nonempty proper suffix v of w satisfies $v > w$. By the definition of a Lyndon word, this yields that w is Lyndon (since w is nonempty), so that Assertion $\mathcal{A}$ holds. Hence, the implication $\mathcal{B} \Longrightarrow \mathcal{A}$ is proven.

Proof of the implication $\mathcal{C} \Longrightarrow \mathcal{B}$: Assume that Assertion $\mathcal{C}$ holds. Let us prove that Assertion $\mathcal{B}$ holds.

Indeed, let u and v be two nonempty words satisfying $w = uv$. We will show that $v > w$.

Let us first notice that Assertion $\mathcal{C}$ yields $v > u$.

Let $\mathfrak{K}$ be the set $\left\{k \in \mathbb{N} \mid u^k \text{ is a prefix of } v\right\}$. The integer 0 belongs to this set $\mathfrak{K}$ (since $u^0 = \varnothing$ is a prefix of v), and therefore $\mathfrak{K}$ is nonempty. Also, this set $\mathfrak{K}$ is finite[957]. Hence, the set $\mathfrak{K}$ has a maximum element (since it is nonempty and finite). Let m be this maximum element. Then, $m \in \mathfrak{K}$ but $m + 1 \notin \mathfrak{K}$.

We have $m \in \mathfrak{K} = \left\{k \in \mathbb{N} \mid u^k \text{ is a prefix of } v\right\}$. Thus, m is an element of $\mathbb{N}$ such that u^m is a prefix of v. In other words, there exists a word $v' \in \mathfrak{A}^*$ such that $v = u^m v'$. Consider this v'. Using $m + 1 \notin \mathfrak{K}$, it is easy to see that u is not a prefix of v' [958].

It is easy to see that the word v' is nonempty[959]. Also, the word uu^m is nonempty (since u is nonempty). We have $w = u \underbrace{v}_{=u^m v'} = uu^m v'$. Therefore, Assertion $\mathcal{C}$ (applied to uu^m and v' instead of u and v) yields $v' > uu^m \geq u$. Thus, $u \leq v'$. Hence, Proposition 6.1.2(d) (applied to $a = u$, $b = v'$, $c = v'$ and $d = \varnothing$) yields that either we have $uv' \leq v'\varnothing$ or the word u is a prefix of v'. Since we know that the word u is not a prefix of v', we can thus conclude that $uv' \leq v'\varnothing$. Thus, $uv' \leq v'\varnothing = v'$. Hence, Proposition 6.1.2(b) (applied

[957] *Proof.* Let i be an element of $\mathfrak{K}$. Thus, $i \in \mathfrak{K} = \left\{k \in \mathbb{N} \mid u^k \text{ is a prefix of } v\right\}$. In other words i is an element of $\mathbb{N}$ such that u^i is a prefix of v. The word u^i is not longer than v (since it is a prefix of v); thus $\ell\left(u^i\right) \leq \ell(v)$. But u is nonempty, and thus $\ell(u) \geq 1$. Hence, $\ell\left(u^i\right) = i \underbrace{\ell(u)}_{\geq 1} \geq i$, so that $i \leq \ell\left(u^i\right) \leq \ell(v)$.

Now, let us forget that we fixed i. We thus have proven that every element i of $\mathfrak{K}$ satisfies $i \leq \ell(v)$. Thus, there are only finitely many elements of $\mathfrak{K}$ (since there are only finitely many $i \in \mathbb{N}$ satisfying $i \leq \ell(v)$). In other words, the set $\mathfrak{K}$ is finite.

[958] *Proof.* Assume the contrary. Thus, u is a prefix of v'. In other words, there exists a word $t \in \mathfrak{A}^*$ such that $v' = ut$. Consider this t. We have $v = u^m \underbrace{v'}_{=ut} = \underbrace{u^m u}_{=u^{m+1}} t = u^{m+1} t$, and thus the word u^{m+1} is a prefix of v. Hence, $m + 1$ is an element of $\mathbb{N}$ such that u^{m+1} is a prefix of v. In other words, $m + 1 \in \left\{k \in \mathbb{N} \mid u^k \text{ is a prefix of } v\right\} = \mathfrak{K}$. But this contradicts $m + 1 \notin \mathfrak{K}$. This contradiction proves that our assumption was wrong, qed.

[959] *Proof.* Assume the contrary. Thus, the word v' is empty; that is, we have $v' = \varnothing$. Now, $v = u^m \underbrace{v'}_{=\varnothing} = u^m$ and $w = u \underbrace{v}_{=u^m} = uu^m = u^{m+1} = \underbrace{u^m}_{=v} u = vu$. Hence, Assertion $\mathfrak{C}$ (applied to v and u instead of u and v) yields $u > v$. This contradicts $v > u$. This contradiction proves that our assumption was wrong, qed.

to $a = u^m$, $c = uv'$ and $d = v'$) yields $u^m uv' \leq u^m v'$. Thus, $u^m v' \geq \underbrace{u^m u}_{=u^{m+1}=uu^m} v' = uu^m v' = w$. Since $u^m v' = v$, this rewrites as $v \geq w$. Hence, $v > w$ [960].

Now, let us forget that we fixed u and v. We thus have proven that any nonempty words u and v satisfying $w = uv$ satisfy $v > w$. In other words, Assertion $\mathcal{B}$ holds. Hence, the implication $\mathcal{C} \Longrightarrow \mathcal{B}$ is proven.

Proof of the implication $\mathcal{D} \Longrightarrow \mathcal{B}$: Assume that Assertion $\mathcal{D}$ holds. Let us prove that Assertion $\mathcal{B}$ holds.

We shall prove Assertion $\mathcal{B}$ by strong induction over $\ell(u)$:

Induction step: Let $N \in \mathbb{N}$. Assume that Assertion $\mathcal{B}$ holds in the case when $\ell(u) < N$. We now need to prove Assertion $\mathcal{B}$ in the case when $\ell(u) = N$.

We have assumed that Assertion $\mathcal{B}$ holds in the case when $\ell(u) < N$. In other words,

$$\text{any nonempty words } u \text{ and } v \text{ satisfying } w = uv \text{ and } \ell(u) < N \text{ satisfy } v > w. \tag{13.139.3}$$

Now, let u and v be two nonempty words satisfying $w = uv$ and $\ell(u) = N$. We shall prove that $v > w$.

From Assertion $\mathcal{D}$, we obtain $vu > uv$. Thus, $uv < vu$. Hence, Exercise 6.1.21(a) yields that there exists a nonempty suffix s of u satisfying $sv < v$. Consider this s. There exists a $p \in \mathfrak{A}^*$ such that $u = ps$ (since s is a suffix of u). Consider this p. Since s is nonempty, we have $\ell(s) > 0$. Now, $\ell\left(\underbrace{u}_{=ps}\right) = \ell(ps) = \ell(p) + \underbrace{\ell(s)}_{>0} > \ell(p)$, so that $\ell(p) < \ell(u) = N$. Also, $w = \underbrace{u}_{=ps} v = psv$. Furthermore, if $p = \varnothing$, then $v > w$ is true[961]. Hence, for the rest of our proof of $v > w$, we can WLOG assume that we don't have $p = \varnothing$. Assume this. Thus, $p \neq \varnothing$, so that the word p is nonempty. Also, the word sv is nonempty (since v is nonempty).

Now, the words p and sv are nonempty and satisfy $w = psv$ and $\ell(p) < N$. Hence, we can apply (13.139.3) to p and sv instead of u and v. As a result, we obtain $sv > w$. But $sv < v$, so that $v > sv > w$. Hence, we have proven that $v > w$.

Now, let us forget that we fixed u and v. We thus have proven that any nonempty words u and v satisfying $w = uv$ and $\ell(u) = N$ satisfy $v > w$. In other words, we have proven Assertion $\mathcal{B}$ in the case when $\ell(u) = N$. Hence, the induction step is complete. Assertion $\mathcal{B}$ is thus proven by strong induction. And so, we have established the implication $\mathcal{D} \Longrightarrow \mathcal{B}$.

Combining the implications $\mathcal{A} \Longrightarrow \mathcal{B}$, $\mathcal{A} \Longrightarrow \mathcal{C}$, $\mathcal{A} \Longrightarrow \mathcal{D}$, $\mathcal{B} \Longrightarrow \mathcal{A}$, $\mathcal{C} \Longrightarrow \mathcal{B}$ and $\mathcal{D} \Longrightarrow \mathcal{B}$ that we have proven, we obtain the equivalence $\mathcal{A} \Longleftrightarrow \mathcal{B} \Longleftrightarrow \mathcal{C} \Longleftrightarrow \mathcal{D}$. Hence, Theorem 6.1.20 is proven again. □

13.140. **Solution to Exercise 6.1.22.** *Solution to Exercise 6.1.22.* Let us first assume that w is Lyndon. We shall prove that

$$\left(\text{every nonempty word } t \text{ and every positive integer } n \text{ satisfy } \left(\text{if } w \leq t^n, \text{ then } w \leq t\right)\right). \tag{13.140.1}$$

Let t be a nonempty word, and let n be a positive integer. Assume that $w \leq t^n$. We need to prove that $w \leq t$.

Assume the contrary. Thus, we don't have $w \leq t$. In other words, we don't have $w \leq t^1$.

Let m be the minimal $i \in \{1, 2, \ldots, n\}$ satisfying $w \leq t^i$. [962] Then, $w \leq t^m$. Hence, $m \neq 1$ (because $w \leq t^m$, but we don't have $w \leq t^1$). Thus, $m \geq 2$, so that $m - 1$ is also an element of $\{1, 2, \ldots, n\}$. If we had $w \leq t^{m-1}$, then $m - 1$ would be an $i \in \{1, 2, \ldots, n\}$ satisfying $w \leq t^i$, which would contradict the fact that m is the **minimal** such i. Thus, we cannot have $w \leq t^{m-1}$.

[960] *Proof.* We have $\ell\left(\underbrace{w}_{=uv}\right) = \ell(uv) = \underbrace{\ell(u)}_{\substack{>0 \\ (\text{since } u \text{ is nonempty})}} + \ell(v) > \ell(v)$, so that $\ell(w) \neq \ell(v)$ and thus $w \neq v$. Combined with $v \geq w$, this yields $v > w$, qed.

[961] *Proof.* Assume that $p = \varnothing$. Then, $u = \underbrace{p}_{=\varnothing} s = s$, so that $s = u$. Then, $\underbrace{s}_{=u} v = uv = w$, so that $w = sv < v$ and thus $v > w$, qed.

[962] Such an i exists, because $n \in \{1, 2, \ldots, n\}$ satisfies $w \leq t^n$.

But $w\varnothing = w \leq t^{m-1}t$. Hence, Proposition 6.1.2(e) (applied to $a = w$, $b = \varnothing$, $c = t^{m-1}$ and $d = t$) yields that either we have $w \leq t^{m-1}$ or the word t^{m-1} is a prefix of w. Since we cannot have $w \leq t^{m-1}$, this shows that the word t^{m-1} is a prefix of w. In other words, there exists a $v \in \mathfrak{A}^*$ such that $w = t^{m-1}v$. Consider this v. We have $v \neq \varnothing$ (because otherwise, we would have $v = \varnothing$ and thus $w = t^{m-1}\underbrace{v}_{=\varnothing} = t^{m-1} \leq t^{m-1}$, contradicting the fact that we cannot have $w \leq t^{m-1}$), so that v is nonempty. Hence, Proposition 6.1.14(b) (applied to $u = t^{m-1}$) now yields $v > t^{m-1}$. Hence, $t^{m-1} < v$. Thus, Proposition 6.1.2(b) (applied to $a = t^{m-1}$, $c = t^{m-1}$ and $d = v$) yields $t^{m-1}t^{m-1} \leq t^{m-1}v = w$. Hence,

$$w \geq t^{m-1}t^{m-1} = t^{2(m-1)}.$$

Combined with

$$\begin{aligned} w \leq t^m \leq t^m t^{m-2} \qquad & \text{(this makes sense since } m \geq 2) \\ = t^{m+(m-2)} = t^{2(m-1)}, & \end{aligned}$$

this yields $w = t^{2(m-1)} = t^{m-1}t^{m-1}$, so that $t^{m-1}t^{m-1} = w = t^{m-1}v$. Cancelling t^{m-1} in this, we obtain $t^{m-1} = v$, which contradicts $t^{m-1} < v$. This contradiction shows that our assumption (that we don't have $w \leq t$) was false. Hence, $w \leq t$.

Forget now that we assumed that $w \leq t^n$. We thus have proven that if $w \leq t^n$, then $w \leq t$.

Now, forget that we fixed t and assumed that w is Lyndon. We thus have shown that

$$\text{(if } w \text{ is Lyndon, then (13.140.1) holds)}. \tag{13.140.2}$$

Now, conversely, assume that (13.140.1) holds. We will prove that w is Lyndon.

In fact, assume the contrary. Then, w is not Lyndon. Let v be the (lexicographically) smallest nonempty suffix of w. Proposition 6.1.19(b) yields that there exists a nonempty $u \in \mathfrak{A}^*$ such that $w = uv$, $u \geq v$ and $uv \geq vu$. Consider this u. We have $u \geq v$, thus $v \leq u$, and therefore Proposition 6.1.2(b) (applied to $a = u$, $c = v$ and $d = u$) yields $uv \leq uu$. Now, $w = uv \leq uu = u^2$. Thus, (13.140.1) (applied to $t = u$ and $n = 2$) yields $w \leq u$. But this contradicts the fact that $w = uv > u$ (since v is nonempty). As this contradiction shows, our assumption was wrong. Thus, we have shown that w is Lyndon.

Now, forget that we fixed w. We thus have proven that

$$\text{(if (13.140.1) holds, then } w \text{ is Lyndon)}.$$

Combined with (13.140.2), this yields that w is Lyndon if and only if (13.140.1) holds. This solves the exercise.

13.141. **Solution to Exercise 6.1.23.** *Solution to Exercise 6.1.23.* We will solve Exercise 6.1.23 by induction over n:

The *induction base* is the case $n = 1$; this case is vacuously true (since $w_1 < w_n$ is impossible for $n = 1$).

For the *induction step*, we fix a positive integer $N > 1$, and we assume that Exercise 6.1.23 has been solved for $n = N - 1$. We now must solve Exercise 6.1.23 for $n = N$.

So let w_1, w_2, ..., w_N be N Lyndon words. Assume that $w_1 \leq w_2 \leq \cdots \leq w_N$ and $w_1 < w_N$. We need to show that $w_1 w_2 \cdots w_N$ is a Lyndon word.

Proposition 6.1.16(a) (applied to $u = w_1$ and $v = w_N$) yields that the word $w_1 w_N$ is Lyndon. If $N = 2$, then this yields that $w_1 w_2 \cdots w_N$ is Lyndon (because $w_1 w_2 \cdots w_N = w_1 w_N$ if $N = 2$). Thus, if $N = 2$, then we are done. We therefore WLOG assume that we don't have $N = 2$. Hence, $N \geq 3$. Thus, $w_3 w_4 \cdots w_N$ is a nonempty product. More precisely, $w_3 w_4 \cdots w_N$ is a nonempty product of nonempty words (since the words w_3, w_4, ..., w_N are nonempty (because they are Lyndon)), and therefore a nonempty word itself. Hence, $w_2 < w_2 (w_3 w_4 \cdots w_N) = w_2 w_3 \cdots w_N$.

We have $w_1 \leq w_2 \leq \cdots \leq w_N$. Hence, $w_2 \leq w_3 \leq \cdots \leq w_N$ and, in particular, $w_2 \leq w_N$. We distinguish between two cases:

Case 1: We have $w_2 = w_N$.

Case 2: We have $w_2 \neq w_N$.

Let us first consider Case 1. In this case, we have $w_2 = w_N$. Hence, $w_1 < w_N = w_2$. Thus, Proposition 6.1.16(a) (applied to $u = w_1$ and $v = w_2$) yields that the word $w_1 w_2$ is Lyndon. Moreover, $w_1 w_2 < w_2$ (by

Proposition 6.1.16(b), applied to $u = w_1$ and $v = w_2$). Hence, $w_1 w_2 \leq w_3 \leq w_4 \leq \cdots \leq w_N$ (this follows by combining $w_1 w_2 < w_2$ and $w_2 \leq w_3 \leq \cdots \leq w_N$) and $w_1 w_2 < w_2 = w_N$. Thus, we can apply Exercise 6.1.23 to $N-1$ and $(w_1 w_2, w_3, w_4, \ldots, w_N)$ instead of n and $(w_1, w_2, \ldots, w_n)$ (because we have assumed that Exercise 6.1.23 has been solved for $n = N-1$). We thus obtain that $w_1 w_2 w_3 w_4 \cdots w_N$ is a Lyndon word. In other words, $w_1 w_2 \cdots w_N$ is a Lyndon word. So we have shown that $w_1 w_2 \cdots w_N$ is a Lyndon word in Case 1.

Let us now consider Case 2. In this case, we have $w_2 \neq w_N$. Since $w_2 \leq w_N$, this yields $w_2 < w_N$. Thus, we can apply Exercise 6.1.23 to $N-1$ and $(w_2, w_3, \ldots, w_N)$ instead of n and $(w_1, w_2, \ldots, w_n)$ (because we have assumed that Exercise 6.1.23 has been solved for $n = N-1$). We thus obtain that $w_2 w_3 \cdots w_N$ is a Lyndon word. Now, w_1 and $w_2 w_3 \cdots w_N$ are two Lyndon words satisfying $w_1 \leq w_2 < w_2 w_3 \cdots w_N$. Therefore, Proposition 6.1.16(a) (applied to $u = w_1$ and $v = w_2 w_3 \cdots w_N$) yields that the word $w_1 w_2 w_3 \cdots w_N$ is Lyndon. In other words, the word $w_1 w_2 \cdots w_N$ is Lyndon. So we have shown that $w_1 w_2 \cdots w_N$ is a Lyndon word in Case 2.

Now, we have proven that $w_1 w_2 \cdots w_N$ is a Lyndon word in both possible Cases 1 and 2. Hence, $w_1 w_2 \cdots w_N$ always is a Lyndon word. In other words, Exercise 6.1.23 is solved for $n = N$. This completes the induction, and therefore Exercise 6.1.23 is solved.

13.142. **Solution to Exercise 6.1.24.**

Solution to Exercise 6.1.24. We have assumed that

$$w_i w_{i+1} \cdots w_n \geq w_1 w_2 \cdots w_n \qquad \text{for every } i \in \{1, 2, \ldots, n\}. \tag{13.142.1}$$

As a consequence,

$$w_i w_{i+1} \cdots w_n > w_1 w_2 \cdots w_n \qquad \text{for every } i \in \{2, 3, \ldots, n\}. \tag{13.142.2}$$

[963]

Now, we claim that if j is any element of $\{0, 1, \ldots, n\}$, then

$$\text{every nonempty proper suffix } v \text{ of } w_{n-j+1} w_{n-j+2} \cdots w_n \text{ satisfies } v > w_1 w_2 \cdots w_n. \tag{13.142.3}$$

Proof of (13.142.3): We will prove (13.142.3) by induction over j:

Induction base: For $j = 0$, we have $w_{n-j+1} w_{n-j+2} \cdots w_n = w_{n-0+1} w_{n-0+2} \cdots w_n = (\text{empty product}) = \varnothing$. Hence, for $j = 0$, the word $w_{n-j+1} w_{n-j+2} \cdots w_n$ has no nonempty proper suffix. Thus, (13.142.3) is vacuously true for $j = 0$. The induction base is thus complete.

Induction step: Let $J \in \{0, 1, \ldots, n-1\}$. We assume that (13.142.3) holds for $j = J$. We now need to prove that (13.142.3) holds for $j = J + 1$.

From $J \in \{0, 1, \ldots, n-1\}$, we obtain $n - J \in \{1, 2, \ldots, n\}$.

Let $g = w_{n-J+1} w_{n-J+2} \cdots w_n$. We have assumed that (13.142.3) holds for $j = J$. In other words, every nonempty proper suffix v of $w_{n-J+1} w_{n-J+2} \cdots w_n$ satisfies $v > w_1 w_2 \cdots w_n$. Since $w_{n-J+1} w_{n-J+2} \cdots w_n = g$, this rewrites as follows:

$$\text{Every nonempty proper suffix } v \text{ of } g \text{ satisfies } v > w_1 w_2 \cdots w_n. \tag{13.142.4}$$

Now, let us notice that

$$\begin{aligned} w_{n-(J+1)+1} w_{n-(J+1)+2} \cdots w_n = w_{n-J} w_{n-J+1} \cdots w_n &= w_{n-J} \underbrace{(w_{n-J+1} w_{n-J+2} \cdots w_n)}_{=g} \\ &= w_{n-J} g. \end{aligned} \tag{13.142.5}$$

Let now v be a nonempty proper suffix of $w_{n-J} g$. We are going to prove that $v > w_1 w_2 \cdots w_n$.

We have $v \neq \varnothing$ (since v is nonempty). Since v is a nonempty suffix of $w_{n-J} g$, we must be in one of the following two cases (depending on whether this suffix begins before the suffix g of $w_{n-J} g$ begins or afterwards):

[963] *Proof of (13.142.2):* Let $i \in \{2, 3, \ldots, n\}$. Then, $i - 1 \geq 1$. The words w_1, w_2, $\ldots$, w_{i-1} are Lyndon (since the words w_1, w_2, $\ldots$, w_n are Lyndon), and thus nonempty. Now, $i - 1 \geq 1 > 0$. Hence, the product $w_1 w_2 \cdots w_{i-1}$ is a nonempty product of nonempty words (since w_1, w_2, $\ldots$, w_{i-1} are nonempty words), and thus a nonempty word itself. Since $w_1 w_2 \cdots w_n = (w_1 w_2 \cdots w_{i-1})(w_i w_{i+1} \cdots w_n)$, this yields that $w_i w_{i+1} \cdots w_n$ is a **proper** suffix of the word $w_1 w_2 \cdots w_n$. As a consequence, $w_i w_{i+1} \cdots w_n \neq w_1 w_2 \cdots w_n$. Combining this with $w_i w_{i+1} \cdots w_n \geq w_1 w_2 \cdots w_n$ (by (13.142.1)), we obtain $w_i w_{i+1} \cdots w_n > w_1 w_2 \cdots w_n$. This proves (13.142.2).

Case 1: The word v is a nonempty suffix of g. (Note that v is allowed to be g.)

Case 2: The word v has the form hg where h is a nonempty suffix of w_{n-J}.

Let us first consider Case 1. In this case, the word v is a nonempty suffix of g. If v is a proper suffix of g, then we immediately obtain $v > w_1 w_2 \cdots w_n$ (from (13.142.4)). Thus, for the rest of the proof of $v > w_1 w_2 \cdots w_n$ in Case 1, we can WLOG assume that v is not a proper suffix of g. Assume this.

So we know that v is a suffix of g, but not a proper suffix of g. Hence, v must be g itself. That is, we have $v = g$. Hence, $v = g = w_{n-J+1} w_{n-J+2} \cdots w_n$. Consequently, $J \neq 0$ [964]. Combined with $J \in \{0, 1, \ldots, n-1\}$, this yields $J \in \{0, 1, \ldots, n-1\} \setminus \{0\} = \{1, 2, \ldots, n-1\}$, so that $n-J+1 \in \{2, 3, \ldots, n\}$. Now,

$$v = g = w_{n-J+1} w_{n-J+2} \cdots w_n = w_{n-J+1} w_{(n-J+1)+1} \cdots w_n > w_1 w_2 \cdots w_n$$

(by (13.142.2), applied to $i = n - J + 1$). Thus, $v > w_1 w_2 \cdots w_n$ is proven in Case 1.

Let us now consider Case 2. In this case, the word v has the form hg where h is a nonempty suffix of w_{n-J}. Consider this h. Since h is a suffix of w_{n-J}, we have $\ell(h) \leq \ell(w_{n-J})$, so that $\ell(w_{n-J}) \geq \ell(h)$. But w_{n-J} is a Lyndon word (since w_1, w_2, $\ldots$, w_n are Lyndon words), and thus $h \geq w_{n-J}$ (by Corollary 6.1.15, applied to w_{n-J} and h instead of w and v). Thus, $w_{n-J} \leq h$. Thus, Proposition 6.1.2(j) (applied to $a = w_{n-J}$, $b = h$ and $c = g$) yields $w_{n-J} g \leq hg = v$. Thus, $v \geq w_{n-J} g$.

But we also have $v \neq w_{n-J} g$ (since v is a proper suffix of $w_{n-J} g$). Combined with $v \geq w_{n-J} g$, this yields $v > w_{n-J} g$, so that

$$\begin{aligned} v > w_{n-J} g &= w_{n-(J+1)+1} w_{n-(J+1)+2} \cdots w_n && \text{(by (13.142.5))} \\ &= w_{n-J} w_{n-J+1} \cdots w_n \geq w_1 w_2 \cdots w_n && \text{(by (13.142.1), applied to } i = n - J) . \end{aligned}$$

Thus, $v > w_1 w_2 \cdots w_n$ is proven in Case 2.

Now, $v > w_1 w_2 \cdots w_n$ is proven in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this yields that $v > w_1 w_2 \cdots w_n$ always holds.

Now, let us forget that we fixed v. We thus have proven that every nonempty proper suffix v of $w_{n-J} g$ satisfies $v > w_1 w_2 \cdots w_n$. Since $w_{n-J} g = w_{n-(J+1)+1} w_{n-(J+1)+2} \cdots w_n$ (by (13.142.5)), this rewrites as follows: Every nonempty proper suffix v of $w_{n-(J+1)+1} w_{n-(J+1)+2} \cdots w_n$ satisfies $v > w_1 w_2 \cdots w_n$. In other words, (13.142.3) holds for $j = J + 1$. This completes the induction step. Thus, (13.142.3) is proven by induction.

Now, we can apply (13.142.3) to $j = n$. As a result, we obtain that every nonempty proper suffix v of $w_{n-n+1} w_{n-n+2} \cdots w_n$ satisfies $v > w_1 w_2 \cdots w_n$. In other words, every nonempty proper suffix v of $w_1 w_2 \cdots w_n$ satisfies $v > w_1 w_2 \cdots w_n$ (since $w_{n-n+1} w_{n-n+2} \cdots w_n = w_1 w_2 \cdots w_n$). Since the word $w_1 w_2 \cdots w_n$ is also nonempty[965], this shows that the word $w_1 w_2 \cdots w_n$ is Lyndon (by the definition of a Lyndon word). This solves Exercise 6.1.24.

13.143. **Solution to Exercise 6.1.29.**

Solution to Exercise 6.1.29. Let us first forget about the setting of Exercise 6.1.29 (so $\mathfrak{A}$ can be any alphabet, not necessarily finite).

Our solution to Exercise 6.1.29 will rely on two basic propositions:

Proposition 13.143.1. *Let $\mathfrak{M}$ denote the set of all finite multisets of Lyndon words.*

Define a map $\mathbf{m} : \mathfrak{M} \to \mathfrak{A}^*$ as follows: Given an $M \in \mathfrak{M}$, we set $\mathbf{m}(M) = a_1 a_2 \cdots a_k$, where $a_1, a_2, \ldots, a_k$ denote the elements of M listed in decreasing order[966]*. Thus, a map $\mathbf{m} : \mathfrak{M} \to \mathfrak{A}^*$ is defined.*

[964] *Proof.* Assume the contrary. Then, $J = 0$, so that

$$\begin{aligned} v = w_{n-J+1} w_{n-J+2} \cdots w_n &= w_{n-0+1} w_{n-0+2} \cdots w_n && \text{(since } J = 0) \\ &= (\text{empty product}) = \varnothing, \end{aligned}$$

contradicting the fact that $v \neq \varnothing$. This contradiction shows that our assumption was wrong, qed.

[965] *Proof.* The product $w_1 w_2 \cdots w_n$ is nonempty (since n is a positive integer), and the words w_1, w_2, $\ldots$, w_n are nonempty (since they are Lyndon words). Hence, $w_1 w_2 \cdots w_n$ is a nonempty product of nonempty words. Thus, $w_1 w_2 \cdots w_n$ is a nonempty word, qed.

[966] When we say "the elements of M listed in decreasing order", we mean that $(a_1, a_2, \ldots, a_k)$ should be the unique tuple satisfying $a_1 \geq a_2 \geq \cdots \geq a_k$ and $M = \{a_1, a_2, \ldots, a_k\}_{\text{multiset}}$. (The existence and the uniqueness of this tuple follow from basic properties of finite multisets, since $\geq$ is a total order.) Note that each element appears in the tuple $(a_1, a_2, \ldots, a_k)$ with the same multiplicity with which it appears in the multiset M.

Let $\mathbf{n} : \mathfrak{A}^* \to \mathfrak{M}$ *be the map that sends each word* $w \in \mathfrak{A}^*$ *to the multiset* $\{a_1, a_2, \ldots, a_k\}_{\text{multiset}}$, *where* $(a_1, a_2, \ldots, a_k)$ *is the CFL factorization of* w.

Then, these two maps $\mathbf{m}$ *and* $\mathbf{n}$ *are mutually inverse bijections.*

Note that $\mathfrak{A}$ is **not** assumed to be finite in Proposition 13.143.1.

Proof of Proposition 13.143.1. This follows from the definition of the CFL factorization (and from the fact that it exists and is unique).[967] □

Proposition 13.143.2. *Let* S *be any set.*

Let $\mathfrak{M}$ *be the set of all finite multisets of elements of* S.

Let $\mathfrak{N}$ *be the set of all families* $(k_w)_{w \in S} \in \mathbb{N}^S$ *of nonnegative integers (indexed by the elements of* S*) such that all but finitely many* $w \in S$ *satisfy* $k_w = 0$.

Then, the map mult $: \mathfrak{M} \to \mathfrak{N}$ *that sends each multiset* $M \in \mathfrak{M}$ *to the family*

$$\left(\textit{(multiplicity of } w \textit{ in the multiset } M)\right)_{w \in S} \in \mathfrak{N}$$

is well-defined and is a bijection.

Example 13.143.3. If $S = \mathbb{N}$, then the map mult defined in Proposition 13.143.2 sends the finite multiset $\{1, 4, 4, 5\}_{\text{multiset}} \in \mathfrak{M}$ to the family $(k_w)_{w \in S} \in \mathbb{N}^S$, where

$$k_1 = 1, \qquad k_4 = 2, \qquad k_5 = 1, \qquad \text{and } k_w = 0 \text{ for all } w \notin \{1, 4, 5\}.$$

Proof of Proposition 13.143.2. It is straightforward to see that the map mult is well-defined. On the other hand, the map

$$\mathfrak{N} \to \mathfrak{M},$$
$$(k_w)_{w \in S} \mapsto (\text{the multiset that contains each } w \in S \text{ with multiplicity } k_w)$$

is also well-defined. These two maps are clearly mutually inverse. Thus, the map mult is invertible, i.e., is a bijection. This proves Proposition 13.143.2. □

Let us now solve Exercise 6.1.29. Let $\mathfrak{A}$ and q be as in Exercise 6.1.29.

For every positive integer n, let $\operatorname{lyn} n$ denote the number of Lyndon words of length n. We need to prove that

$$(13.143.1) \qquad \operatorname{lyn} n = \frac{1}{n} \sum_{d \mid n} \mu(d)\, q^{n/d} \qquad \text{for every positive integer } n.$$

Let $\mathfrak{M}$ denote the set of all finite multisets of Lyndon words. Define two maps $\mathbf{m} : \mathfrak{M} \to \mathfrak{A}^*$ and $\mathbf{n} : \mathfrak{A}^* \to \mathfrak{M}$ as in Proposition 13.143.1. Then, Proposition 13.143.1 shows that these two maps $\mathbf{m}$ and $\mathbf{n}$ are mutually inverse bijections. Hence, the map $\mathbf{m}$ is a bijection.

On the other hand, let $\mathfrak{L}$ be the set of all Lyndon words. Thus, the Lyndon words are precisely the elements of $\mathfrak{L}$. But the definition of $\mathfrak{M}$ says that $\mathfrak{M}$ is the set of all finite multisets of Lyndon words. In other words, $\mathfrak{M}$ is the set of all finite multisets of elements of $\mathfrak{L}$ (since the Lyndon words are precisely the elements of $\mathfrak{L}$).

The definition of $\operatorname{lyn} n$ now rewrites as

$$(13.143.2) \qquad \operatorname{lyn} n = |\{w \in \mathfrak{L} \mid \ell(w) = n\}| \qquad \text{for every positive integer } n$$

For example, if $M = \{2, 2, 3536, 24\}_{\text{multiset}}$, then $(a_1, a_2, \ldots, a_k) = (3536, 24, 2, 2)$.

[967] Here are a few details:

- The equality $\mathbf{m} \circ \mathbf{n} = \operatorname{id}$ follows immediately from the definition of the CFL factorization.
- In order to prove the equality $\mathbf{n} \circ \mathbf{m} = \operatorname{id}$, we fix some $M \in \mathfrak{M}$; our goal is thus to show that $(\mathbf{n} \circ \mathbf{m})(M) = M$. Let $a_1, a_2, \ldots, a_k$ denote the elements of M listed in decreasing order (so that $M = \{a_1, a_2, \ldots, a_k\}_{\text{multiset}}$ and $a_1 \geq a_2 \geq \cdots \geq a_k$). The definition of $\mathbf{m}$ then yields $\mathbf{m}(M) = a_1 a_2 \cdots a_k$. Hence, $a_1, a_2, \ldots, a_k$ are the elements of M, and thus are Lyndon words (since M is a multiset of Lyndon words). Therefore, $(a_1, a_2, \ldots, a_k)$ is a tuple of Lyndon words satisfying $\mathbf{m}(M) = a_1 a_2 \cdots a_k$ and $a_1 \geq a_2 \geq \cdots \geq a_k$. In other words, $(a_1, a_2, \ldots, a_k)$ is a CFL factorization of $\mathbf{m}(M)$ (by the definition of a CFL factorization). Since the CFL factorization of a word is unique, this shows that $(a_1, a_2, \ldots, a_k)$ is **the** CFL factorization of $\mathbf{m}(M)$. Hence, the definition of $\mathbf{n}$ yields $\mathbf{n}(\mathbf{m}(M)) = \{a_1, a_2, \ldots, a_k\}_{\text{multiset}} = M$. In other words, $(\mathbf{n} \circ \mathbf{m})(M) = M$. This concludes the proof of $\mathbf{n} \circ \mathbf{m} = \operatorname{id}$.

Combining the equalities $\mathbf{m} \circ \mathbf{n} = \operatorname{id}$ and $\mathbf{n} \circ \mathbf{m} = \operatorname{id}$, we conclude that the maps $\mathbf{m}$ and $\mathbf{n}$ are mutually inverse, hence bijections.

(since the Lyndon words are precisely the elements of $\mathfrak{L}$).

Let $\mathfrak{N}$ be the set of all families $(k_w)_{w\in\mathfrak{L}} \in \mathbb{N}^{\mathfrak{L}}$ of nonnegative integers (indexed by the Lyndon words) such that all but finitely many $w \in \mathfrak{L}$ satisfy $k_w = 0$. Proposition 13.143.2 (applied to $S = \mathfrak{L}$) shows that the map $\operatorname{mult} : \mathfrak{M} \to \mathfrak{N}$ that sends each multiset $M \in \mathfrak{M}$ to the family

$$((\text{multiplicity of } w \text{ in the multiset } M))_{w\in S} \in \mathfrak{N}$$

is well-defined and is a bijection. Consider this map mult.

The composition $\mathbf{m} \circ \operatorname{mult}^{-1} : \mathfrak{N} \to \mathfrak{A}^*$ of the bijections $\mathbf{m}$ and mult^{-1} is clearly a bijection. It can easily be seen to satisfy

$$\ell\left(\left(\mathbf{m} \circ \operatorname{mult}^{-1}\right)\left((k_w)_{w\in\mathfrak{L}}\right)\right) = \sum_{w\in\mathfrak{L}} k_w \cdot \ell(w) \qquad \text{for every } (k_w)_{w\in\mathfrak{L}} \in \mathfrak{N}. \tag{13.143.3}$$

[968] Now, in the ring $\mathbb{Q}[[t]]$ of formal power series, we have

$$\sum_{w\in\mathfrak{A}^*} t^{\ell(w)} = \sum_{n\in\mathbb{N}} \underbrace{\left|\{w \in \mathfrak{A}^* \mid \ell(w) = n\}\right|}_{\substack{=|\mathfrak{A}^n|=|\mathfrak{A}|^n=q^n \\ (\text{since } |\mathfrak{A}|=q)}} t^n = \sum_{n\in\mathbb{N}} q^n t^n = \frac{1}{1-qt}.$$

[968] *Proof of (13.143.3):* Let $(k_w)_{w\in\mathfrak{L}} \in \mathfrak{N}$. Let $M = \operatorname{mult}^{-1}\left((k_w)_{w\in\mathfrak{L}}\right)$. Then, M is a multiset of elements of $\mathfrak{L}$ and satisfies $(k_w)_{w\in\mathfrak{L}} = \operatorname{mult} M = ((\text{multiplicity of } w \text{ in the multiset } M))_{w\in\mathfrak{L}}$. In other words, every $w \in \mathfrak{L}$ satisfies

$$k_w = (\text{multiplicity of } w \text{ in the multiset } M). \tag{13.143.4}$$

Let $a_1, a_2, \ldots, a_k$ denote the elements of this multiset M listed in decreasing order. Then, the definition of $\mathbf{m}$ yields $\mathbf{m}(M) = a_1 a_2 \cdots a_k$, so that

$$\begin{aligned}
\ell(\mathbf{m}(M)) &= \ell(a_1 a_2 \cdots a_k) = \sum_{i\in\{1,2,\ldots,k\}} \ell(a_i) = \sum_{w\in\mathfrak{L}} \sum_{\substack{i\in\{1,2,\ldots,k\};\\ a_i=w}} \ell\left(\underbrace{a_i}_{\substack{=w \\ (\text{since } a_i=w)}}\right) \qquad (\text{since every } a_i \text{ belongs to } \mathfrak{L}) \\
&= \sum_{w\in\mathfrak{L}} \underbrace{\sum_{\substack{i\in\{1,2,\ldots,k\};\\ a_i=w}} \ell(w)}_{=(\text{number of } i\in\{1,2,\ldots,k\} \text{ satisfying } a_i=w)\cdot\ell(w)} = \sum_{w\in\mathfrak{L}} \underbrace{(\text{number of } i \in \{1,2,\ldots,k\} \text{ satisfying } a_i = w)}_{\substack{=(\text{multiplicity of } w \text{ in the multiset } M)=k_w \\ (\text{by } (13.143.4))}} \cdot \ell(w) \\
&= \sum_{w\in\mathfrak{L}} k_w \cdot \ell(w).
\end{aligned}$$

Now,

$$\ell\left(\left(\mathbf{m} \circ \operatorname{mult}^{-1}\right)\left((k_w)_{w\in\mathfrak{L}}\right)\right) = \ell\left(\mathbf{m}\left(\underbrace{\operatorname{mult}^{-1}\left((k_w)_{w\in\mathfrak{L}}\right)}_{=M}\right)\right) = \ell(\mathbf{m}(M)) = \sum_{w\in\mathfrak{L}} k_w \cdot \ell(w),$$

which proves (13.143.3).

Hence,

$$\begin{aligned}
\frac{1}{1-qt} &= \sum_{w\in\mathfrak{A}^*} t^{\ell(w)} = \sum_{(k_w)_{w\in\mathfrak{L}}\in\mathfrak{N}} t^{\ell\left(\left(\mathbf{m}\circ\operatorname{mult}^{-1}\right)\left((k_w)_{w\in\mathfrak{L}}\right)\right)} \\
&\qquad \left(\begin{array}{c}\text{here, we substituted } \left(\mathbf{m}\circ\operatorname{mult}^{-1}\right)\left((k_w)_{w\in\mathfrak{L}}\right) \text{ for } w \text{ in the sum,}\\ \text{since the map } \mathbf{m}\circ\operatorname{mult}^{-1} : \mathfrak{N}\to\mathfrak{A}^* \text{ is a bijection}\end{array}\right) \\
&= \sum_{(k_w)_{w\in\mathfrak{L}}\in\mathfrak{N}} t^{\sum_{w\in\mathfrak{L}} k_w\cdot\ell(w)} \qquad \text{(by (13.143.3))} \\
&= \sum_{(k_w)_{w\in\mathfrak{L}}\in\mathfrak{N}} \prod_{w\in\mathfrak{L}} t^{k_w\cdot\ell(w)} = \prod_{w\in\mathfrak{L}} \underbrace{\sum_{k\in\mathbb{N}} t^{k\cdot\ell(w)}}_{=\dfrac{1}{1-t^{\ell(w)}}} \qquad \text{(by the product rule)} \\
&= \prod_{w\in\mathfrak{L}} \frac{1}{1-t^{\ell(w)}} = \prod_{n\geq 1} \prod_{\substack{w\in\mathfrak{L};\\ \ell(w)=n}} \underbrace{\frac{1}{1-t^{\ell(w)}}}_{\substack{=\dfrac{1}{1-t^n} \\ \text{(since } \ell(w)=n)}} \qquad \text{(since } \ell(w)\geq 1 \text{ for every } w\in\mathfrak{L}) \\
&= \prod_{n\geq 1} \underbrace{\prod_{\substack{w\in\mathfrak{L};\\ \ell(w)=n}} \frac{1}{1-t^n}}_{\substack{=\left(\dfrac{1}{1-t^n}\right)^{\operatorname{lyn} n} \\ \text{(by (13.143.2))}}} = \prod_{n\geq 1} \left(\frac{1}{1-t^n}\right)^{\operatorname{lyn} n}.
\end{aligned}$$

Taking the logarithm of both sides of this identity, we obtain

$$\begin{aligned}
\log\frac{1}{1-qt} &= \log\left(\prod_{n\geq 1}\left(\frac{1}{1-t^n}\right)^{\operatorname{lyn} n}\right) = \sum_{n\geq 1} (\operatorname{lyn} n)\cdot \underbrace{\log\left(\frac{1}{1-t^n}\right)}_{\substack{=-\log(1-t^n)=\sum_{u\geq 1}\frac{1}{u}(t^n)^u \\ \text{(by the Mercator series for the logarithm)}}} \\
&= \sum_{n\geq 1} (\operatorname{lyn} n)\cdot\sum_{u\geq 1}\frac{1}{u}(t^n)^u = \sum_{n\geq 1}\sum_{u\geq 1}(\operatorname{lyn} n)\frac{1}{u}\underbrace{(t^n)^u}_{=t^{nu}} = \sum_{n\geq 1}\sum_{u\geq 1}(\operatorname{lyn} n)\frac{1}{u}t^{nu} \\
&= \underbrace{\sum_{n\geq 1}\sum_{\substack{v\geq 1;\\ n\mid v}}}_{=\sum_{v\geq 1}\sum_{n\mid v}} (\operatorname{lyn} n)\underbrace{\frac{1}{v/n}}_{=\dfrac{n}{v}} t^v \qquad \text{(here, we substituted } v/n \text{ for } u \text{ in the second sum)} \\
&= \sum_{v\geq 1}\sum_{n\mid v}(\operatorname{lyn} n)\frac{n}{v}t^v = \sum_{n\geq 1}\sum_{d\mid n}(\operatorname{lyn} d)\frac{d}{n}t^n
\end{aligned}$$

(here, we renamed the summation indices v and n as n and d). Since

$$\begin{aligned}
\log\frac{1}{1-qt} &= -\log(1-qt) = \sum_{n\geq 1}\frac{1}{n}(qt)^n \qquad \text{(by the Mercator series for the logarithm)} \\
&= \sum_{n\geq 1}\frac{1}{n}q^n t^n,
\end{aligned}$$

this rewrites as

$$\sum_{n\geq 1}\frac{1}{n}q^n t^n = \sum_{n\geq 1}\sum_{d\mid n}(\operatorname{lyn} d)\frac{d}{n}t^n.$$

Comparing coefficients, we conclude that every positive integer n satisfies

$$\frac{1}{n}q^n = \sum_{d\mid n} (\operatorname{lyn} d) \frac{d}{n}.$$

Multiplying this with n, we obtain

$$q^n = \sum_{d\mid n} (\operatorname{lyn} d) \, d. \tag{13.143.5}$$

Now, recall that every positive integer N satisfies

$$\sum_{d\mid N} \mu(d) = \delta_{N,1}. \tag{13.143.6}$$

[969] Now, every positive integer n satisfies

$$\begin{aligned}\sum_{d\mid n} \mu(d)\, q^{n/d} &= \sum_{e\mid n} \mu(e) \underbrace{q^{n/e}}_{\substack{=\sum_{d\mid n/e}(\operatorname{lyn} d)d \\ \text{(by (13.143.5), applied} \\ \text{to } n/e \text{ instead of } n)}} = \sum_{e\mid n} \mu(e) \sum_{d\mid n/e} (\operatorname{lyn} d)\, d \\ &= \underbrace{\sum_{e\mid n} \sum_{d\mid n/e}}_{=\sum_{d\mid n}\sum_{e\mid n/d}} \mu(e)\, (\operatorname{lyn} d)\, d = \sum_{d\mid n} \underbrace{\sum_{e\mid n/d} \mu(e)}_{\substack{=\delta_{n/d,1} \\ \text{(by (13.143.6), applied} \\ \text{to } N=n/d)}} (\operatorname{lyn} d)\, d \\ &= \sum_{d\mid n} \underbrace{\delta_{n/d,1}}_{=\delta_{n,d}} (\operatorname{lyn} d)\, d = \sum_{d\mid n} \delta_{n,d} (\operatorname{lyn} d)\, d = (\operatorname{lyn} n)\, n.\end{aligned}$$

Dividing this by n, we obtain $\frac{1}{n}\sum_{d\mid n} \mu(d)\, q^{n/d} = \operatorname{lyn} n$. This proves (13.143.1). Thus, Exercise 6.1.29 is solved.

13.144. **Solution to Exercise 6.1.31.** *Solution to Exercise 6.1.31.* The word v is nonempty (since it is Lyndon). Thus, $u \neq w$ [970]. Combined with $u \leq uv = w$, this yields $u < w$.

(b) We have $w = uv$; thus, v is a proper suffix of w (since u is nonempty). Also, the word w is Lyndon, and therefore

$$\text{every nonempty proper suffix of } w \text{ is } > w \tag{13.144.1}$$

(by the definition of a Lyndon word). Applying (13.144.1) to the nonempty proper suffix v of w, we obtain $v > w$. Thus, $w < v$. Hence, $u < w < v$, and this solves Exercise 6.1.31(b).

(a) The word v is Lyndon (by its definition). It remains to prove that the word u is Lyndon.

Recall that a word x is Lyndon if and only if it is nonempty and satisfies the property that every nonempty proper suffix y of x satisfies $y > x$. [971] Applied to $x = u$, this shows that the word u is Lyndon if and only if it is nonempty and satisfies the property that every nonempty proper suffix y of u satisfies $y > u$. Let us now prove that

$$\text{every nonempty proper suffix } y \text{ of } u \text{ satisfies } y > u. \tag{13.144.2}$$

Proof of (13.144.2): Assume the contrary. Then, there exists a nonempty proper suffix y of u which does not satisfy $y > u$. Let p be the **shortest** such suffix. Thus, p is a nonempty proper suffix of u which does not satisfy $p > u$.

Notice that $p \neq u$ (since p is a **proper** suffix of u).

[969] This is one of the most fundamental properties of the number-theoretic Möbius function. For a proof of (13.143.6), see the solution of Exercise 2.9.6. (More precisely, the equality (13.143.6) is obtained from (13.84.3) by renaming n as N.)

[970] *Proof.* Assume the contrary. Then, $u = w$. Hence, $u\varnothing = w = uv$. Cancelling u from this equality, we obtain $\varnothing = v$. Thus, the word v is empty; this contradicts the fact that v is nonempty. This contradiction proves that our assumption was wrong, qed.

[971] This is just a restatement of the definition of a Lyndon word.

There exists a nonempty $t \in \mathfrak{A}^*$ such that $u = tp$ (since p is a proper suffix of u). Consider this t. We have $w = \underbrace{u}_{=tp} v = tpv = t(pv)$, and thus the word pv is a proper suffix of w (since t is nonempty). Also, the word pv is nonempty (since v is nonempty). Hence, pv is a nonempty proper suffix of w. But applying (13.144.1) to the nonempty proper suffix pv of w, we obtain $pv > w = uv$. Thus, $uv < pv$. Hence, Proposition 6.1.2(e) (applied to $a = u$, $b = v$, $c = p$ and $d = v$) yields that either we have $u \leq p$ or the word p is a prefix of u. Since we don't have $u \leq p$ [972], we therefore conclude that the word p is a prefix of u. Hence, $p \leq u$. Combined with $p \neq u$, this yields $p < u$. Combined with $u < v$ (by Exercise 6.1.31(b)), this yields $p < u < v$.

Let us now show that the word p is Lyndon. Indeed, let r be a nonempty proper suffix of p. Then, r is shorter than p (being a proper suffix of p); in other words, $\ell(r) < \ell(p)$. On the other hand, there exists some nonempty $q \in \mathfrak{A}^*$ satisfying $p = qr$ (since r is a proper suffix of p). Consider this q. We have $u = t \underbrace{p}_{=qr} = tqr = (tq)r$. Thus, r is a proper suffix of u (since tq is nonempty (because q is nonempty)). Hence, $r > u$ [973]. Hence, $r > u > p$ (since $p < u$). Now, let us forget that we fixed r. We thus have shown that

$$\text{every nonempty proper suffix } r \text{ of } p \text{ satisfies } r > p.$$

But recall that the word p is Lyndon if and only if it is nonempty and satisfies the property that every nonempty proper suffix r of p satisfies $r > p$. [974] Hence, we conclude that the word p is Lyndon (since we have shown that p is nonempty and satisfies the property that every nonempty proper suffix r of p satisfies $r > p$).

Now, the words p and v are Lyndon and satisfy $p < v$. Thus, Proposition 6.1.16(a) (applied to p instead of u) yields that the word pv is Lyndon. Notice also that $w = \underbrace{u}_{=tp} v = tpv = t(pv)$, and thus pv is a proper suffix of w (since t is nonempty). Hence, pv is a proper suffix of w such that pv is Lyndon. In other words, pv is a proper suffix z of w such that z is Lyndon. Since v is the longest such suffix[975], this yields that pv is not longer than v. In other words, $\ell(pv) \leq \ell(v)$. This contradicts $\ell(pv) = \underbrace{\ell(p)}_{\substack{>0 \\ \text{(since } p \text{ is nonempty)}}} + \ell(v) > \ell(v)$. This contradiction proves that our assumption was wrong. Hence, (13.144.2) is proven.

Now, recall that the word u is Lyndon if and only if it is nonempty and satisfies the property that every nonempty proper suffix y of u satisfies $y > u$. Hence, the word u is Lyndon (because we have shown that u is nonempty and satisfies the property that every nonempty proper suffix y of u satisfies $y > u$). The solution of Exercise 6.1.31(a) is thus complete.

(c) Let us denote by u' and v' the words u and v constructed in Theorem 6.1.30 (to avoid confusing them with the words u and v defined in Exercise 6.1.31). We must then show that $u = u'$ and $v = v'$.

From Theorem 6.1.30, we see that v' is the (lexicographically) smallest nonempty **proper** suffix of w, and that u' is a nonempty word such that $w = u'v'$.

The word v is a nonempty proper suffix of w. Since v' is the smallest such suffix, we thus conclude that $v' \leq v$. We shall now prove that $v' = v$.

Indeed, v is a proper suffix of w. In other words, v is a proper suffix of $u'v'$ (since $w = u'v'$). Hence, we must be in one of the following two cases (depending on whether this suffix begins before the suffix v' of $u'v'$ begins or afterwards):

Case 1: The word v is a proper suffix of v'.

Case 2: The word v has the form qv' where q is a proper suffix of u'. (This suffix q may be empty.)

[972] *Proof.* Assume the contrary. Then, $u \leq p$. Thus, $p \geq u$. Combined with $p \neq u$, this yields $p > u$. This contradicts the fact that p does not satisfy $p > u$. This contradiction proves that our assumption was wrong, qed.

[973] *Proof.* Assume the contrary. Then, we don't have $r > u$. Thus, r is a nonempty proper suffix of u which does not satisfy $r > u$. In other words, r is a nonempty proper suffix y of u which does not satisfy $y > u$. Since the shortest such suffix is p (by the definition of p), this yields that r is not shorter than p. That is, $\ell(r) \geq \ell(p)$. This contradicts $\ell(r) < \ell(p)$. This contradiction proves that our assumption was wrong, qed.

[974] This is just a restatement of the definition of a Lyndon word (applied to p).

[975] *Proof.* We defined v as the longest proper suffix of w such that v is Lyndon. In other words, v is the longest proper suffix z of w such that z is Lyndon, qed.

Let us first consider Case 1. In this case, the word v is a proper suffix of v'. Now, every nonempty proper suffix s of v' satisfies $s > v'$ [976]. Thus, the word v' is nonempty and satisfies the property that every nonempty proper suffix s of v' satisfies $s > v'$. In other words, the word v' is Lyndon (according to the definition of a Lyndon word).

Now, v is the longest proper suffix of w such that v is Lyndon. In other words, v is the longest proper suffix z of w such that z is Lyndon. But v' also is a proper suffix z of w such that z is Lyndon (since v' is Lyndon). Since v is the longest such suffix, this yields that v' is not longer than v. In other words, $\ell(v') \leq \ell(v)$. But since v is a proper suffix of v', we have $\ell(v) < \ell(v') \leq \ell(v)$. This is absurd. Hence, $v' = v$ (since ex falso quodlibet). Thus, $v' = v$ is proven in Case 1.

Let us now consider Case 2. In this case, the word v has the form qv' where q is a proper suffix of u'. Consider this q.

We need to prove that $v' = v$. If $q = \varnothing$, then this is obvious (because if $q = \varnothing$, then $v = \underbrace{q}_{=\varnothing} v' = v'$ and thus $v' = v$). Hence, for the rest of this proof, we can WLOG assume that we don't have $q = \varnothing$. Assume this. The word q is nonempty (since we don't have $q = \varnothing$), and thus v' is a proper suffix of v (since $v = qv'$).

The word v is Lyndon. Hence, every nonempty proper suffix of v is $> v$ (by the definition of a Lyndon word). Applying this to the nonempty proper suffix v' of v, we conclude that $v' > v$. This contradicts $v' \leq v$. This contradiction shows that we have $v' = v$ (since ex falso quodlibet). Thus, $v' = v$ is proven in Case 2.

Now, $v' = v$ is proven in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this yields that $v' = v$ always holds.

Now we have proven that $v' = v$. Cancelling v from the equality $uv = w = u' \underbrace{v'}_{=v} = u'v$, we obtain $u = u'$. Thus, we have $u = u'$ and $v = v'$. This solves Exercise 6.1.31(c).

[*Remark:* We have not used any statement of Theorem 6.1.30 in our above solution. Thus, parts (a) and (b) of Exercise 6.1.31 provide an alternative proof of Theorem 6.1.30 (because Exercise 6.1.31(c) shows that the words u and v defined in Exercise 6.1.31 are precisely the words u and v constructed in Theorem 6.1.30).]

13.145. **Solution to Exercise 6.1.32.** *Solution to Exercise 6.1.32.* (a) Let us prove the implications $\mathcal{A}' \Longrightarrow \mathcal{D}'$ and $\mathcal{D}' \Longrightarrow \mathcal{A}'$.

Proof of the implication $\mathcal{A}' \Longrightarrow \mathcal{D}'$: Assume that Assertion $\mathcal{A}'$ holds. Thus, w is a power of a Lyndon word. Let said Lyndon word be t. Thus, $w = t^n$ for some $n \in \mathbb{N}$. Consider this n. Since w is nonempty, we have $n \geq 1$. Hence, t^{n-1} is well-defined.

We will first show the following simple lemma:

Lemma A: Let u', v' and p be three words, and $N \in \mathbb{N}$ be such that $u'v' = p^N$. Assume that p is not a prefix of u', and that p is not a suffix of v'. Then, $N \leq 1$.

Proof of Lemma A: Assume the contrary. Thus, $N > 1$, so that $N \geq 2$. The word v' is a suffix of $p^{N-1}p$ (since $u'v' = p^N = p^{N-1}p$). Thus, we must be in one of the following two cases (depending on whether this suffix begins before the suffix p of $p^{N-1}p$ begins, or afterwards):

Case 1: The word v' has the form rp where r is a suffix of p^{N-1}.

Case 2: The word v' is a suffix of p.

Let us first consider Case 1. In this case, the word v' has the form rp where r is a suffix of p^{N-1}. Hence, p is a suffix of v', contradicting the fact that p is not a suffix of v'. Hence, Case 1 leads to a contradiction.

Let us now consider Case 2. In this case, the word v' is a suffix of p. In other words, there exists a $q \in \mathfrak{A}^*$ such that $p = qv'$. Consider this q. We have $u'v' = p^N = p^{N-1} \underbrace{p}_{=qv'} = p^{N-1}qv'$. Cancelling v' from this equality, we obtain $u' = p^{N-1}q$. Since $p^{N-1} = pp^{N-2}$ (this is well-defined because $N \geq 2$), this further becomes $u' = \underbrace{p^{N-1}}_{=pp^{N-2}} q = pp^{N-2}q = p\left(p^{N-2}q\right)$. Hence, p is a prefix of u', contradicting the fact that p is not a prefix of u'. We have thus obtained a contradiction in Case 2.

[976] *Proof.* Let s be a nonempty proper suffix of v'. The word s is a proper suffix of v', which (in turn) is a suffix of w. Hence, s is a proper suffix of w. Thus, s is a nonempty proper suffix of w. Since the smallest such suffix is v' (by the definition of v'), this yields $s \geq v'$. Since $s \neq v'$ (because s is a **proper** suffix of v'), this yields $s > v'$, qed.

We have thus obtained a contradiction in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this shows that we always get a contradiction. This completes the proof of Lemma A.

Now, let us return to the proof of the implication $\mathcal{A}' \Longrightarrow \mathcal{D}'$. Let u and v be nonempty words satisfying $w = uv$. We want to show that $vu \geq uv$.

The word t is nonempty (since it is Lyndon); thus, $\ell(t) \geq 1$. Hence, for every sufficiently large $a \in \mathbb{N}$, we have that the word t^a is not a prefix of u [977]. Similarly, for every sufficiently large $b \in \mathbb{N}$, we have that the word t^b is not a suffix of v.

Let A be the largest nonnegative integer a such that t^a is a prefix of u [978]. Thus, t^A is a prefix of u, but t^{A+1} is not a prefix of u. Let B be the largest nonnegative integer b such that t^b is a suffix of v [979]. Thus, t^B is a suffix of v, but t^{B+1} is not a suffix of v.

There exists a $u' \in \mathfrak{A}^*$ such that $u = t^A u'$ (since t^A is a prefix of u). Consider this u'. Recall that t^{A+1} is not a prefix of u. In other words, $t^A t$ is not a prefix of $t^A u'$ (since $t^{A+1} = t^A t$ and $u = t^A u'$).

There exists a $v' \in \mathfrak{A}^*$ such that $v = v' t^B$ (since t^B is a suffix of v). Consider this v'. Recall that t^{B+1} is not a suffix of v. In other words, tt^B is not a suffix of $v' t^B$ (since $t^{B+1} = tt^B$ and $v = v' t^B$).

If the word t was a prefix of u', then $t^A t$ would be a prefix of $t^A u'$, which would contradict the fact that $t^A t$ is not a prefix of $t^A u'$. Thus, t is not a prefix of u'. In particular, $t \neq u'$.

If the word t was a suffix of v', then tt^B would be a suffix of $v' t^B$, which would contradict the fact that tt^B is not a suffix of $v' t^B$. Thus, t is not a suffix of v'. In particular, $t \neq v'$.

But we have $t^n = w = \underbrace{u}_{=t^A u'} \underbrace{v}_{=v' t^B} = t^A u' v' t^B = t^A \left(u' v' t^B\right)$. Hence, t^A is a prefix of t^n; therefore, $A \leq n$ and thus $n - A \geq 0$. Hence, $t^A t^{n-A} = t^n = t^A \left(u' v' t^B\right)$. Cancelling t^A in this equality, we obtain $t^{n-A} = u' v' t^B = (u' v') t^B$, which shows that t^B is a suffix of t^{n-A}. Thus, $B \leq n - A$ and therefore $n - A - B \geq 0$. Hence, $t^{n-A-B} t^B = t^{n-A} = (u' v') t^B$. Cancelling t^B in this yields $t^{n-A-B} = u' v'$. Now, Lemma A (applied to $p = t$ and $N = n - A - B$) yields $n - A - B \leq 1$. Since $n - A - B \geq 0$, this shows that we have either $n - A - B = 0$ or $n - A - B = 1$. We thus must be in one of the following two cases:

Case 1: We have $n - A - B = 0$.

Case 2: We have $n - A - B = 1$.

Let us first consider Case 1. In this case, we have $n - A - B = 0$. Thus, $t^{n-A-B} = u' v'$ rewrites as $t^0 = u' v'$, so that $u' v' = t^0 = \varnothing$. Consequently, $u' = \varnothing$ and $v' = \varnothing$. Now, $u = t^A \underbrace{u'}_{=\varnothing} = t^A$ and $v = \underbrace{v'}_{=\varnothing} t^B = t^B$, so that $\underbrace{v}_{=t^B} \underbrace{u}_{=t^A} = t^B t^A = t^{B+A} = t^{A+B} = \underbrace{t^A}_{=u} \underbrace{t^B}_{=v} = uv \geq uv$. Hence, $vu \geq uv$ is proven in Case 1.

Let us now consider Case 2. In this case, we have $n - A - B = 1$. Thus, $t^{n-A-B} = u' v'$ rewrites as $t^1 = u' v'$, so that $u' v' = t^1 = t$. As a consequence, u' is nonempty (because if u' was empty, then we would have $u' v' = v'$ and thus $v' = u' v' = t$, contradicting $t \neq v'$), so that $\ell(u') > 0$. Now, $\ell\left(\underbrace{t}_{=u'v'}\right) = \underbrace{\ell(u')}_{>0} + \ell(v') > \ell(v')$, and therefore t is not a prefix of v'. Also, v' is nonempty (because if v' was empty, then we would have $u' v' = u'$ and thus $u' = u' v' = t$, contradicting $t \neq u'$). But t is Lyndon, and therefore Proposition 6.1.14(a) (applied to t, u' and v' instead of w, u and v) yields $v' \geq t$. That is, $t \leq v'$. Thus, Proposition 6.1.2(d) (applied to $a = t$, $b = t^{n-1}$, $c = v'$ and $d = t^B u$) yields that either we have $tt^{n-1} \leq v' t^B u$ or the word t is a prefix of

[977] *Proof.* Let $a \in \mathbb{N}$ be such that $a > \ell(u)$. Then, $\ell(t^a) = \underbrace{a}_{>\ell(u)} \underbrace{\ell(t)}_{\geq 1} > \ell(u)$, so that the word t^a is longer than u. Hence, the word t^a is not a prefix of u.

Now, let us forget that we have fixed a. We thus have shown that for every $a \in \mathbb{N}$ satisfying $a > \ell(u)$, we have that the word t^a is not a prefix of u. Consequently, for every sufficiently large $a \in \mathbb{N}$, we have that the word t^a is not a prefix of u, qed.

[978] This is well-defined because of the following two facts:

- There exists an $a \in \mathbb{N}$ such that the word t^a is a prefix of u (namely, $a = 0$).
- For every sufficiently large $a \in \mathbb{N}$, we have that the word t^a is not a prefix of u.

[979] This is well-defined because of the following two facts:

- There exists a $b \in \mathbb{N}$ such that the word t^b is a suffix of v (namely, $b = 0$).
- For every sufficiently large $b \in \mathbb{N}$, we have that the word t^b is not a suffix of v.

v'. Since t is not a prefix of v', this yields $tt^{n-1} \leq v't^B u$. Since $tt^{n-1} = t^n = w = uv$ and $\underbrace{v't^B}_{=v} u = vu$, this rewrites as $uv \leq vu$. Hence, $vu \geq uv$ is proven in Case 2.

We thus have shown that $vu \geq uv$ in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this yields that we always have $vu \geq uv$. Thus, Assertion $\mathcal{D}'$ is satisfied, so we have proven the implication $\mathcal{A}' \Longrightarrow \mathcal{D}'$.

Proof of the implication $\mathcal{D}' \Longrightarrow \mathcal{A}'$: Assume that Assertion $\mathcal{D}'$ holds. Thus, if u and v are nonempty words satisfying $w = uv$, then we have $vu \geq uv$.

We need to prove that Assertion $\mathcal{A}'$ holds, i.e., that w is a power of a Lyndon word. Assume the contrary. Thus, w is not a power of a Lyndon word; hence, w is not a Lyndon word itself. Consequently, there exist nonempty words u and v such that $w = uv$ and $vu \leq uv$ [980]. Consider such a pair of nonempty words u and v with **minimum** $\ell(u)$. The minimality of $\ell(u)$ shows that

$$\text{(13.145.1)} \qquad (\text{if } u' \text{ and } v' \text{ are nonempty words such that } w = u'v' \text{ and } v'u' \leq u'v', \text{ then } \ell(u') \geq \ell(u)).$$

We have $vu \leq uv$. In combination with $vu \geq uv$ (which follows from Assertion $\mathcal{D}'$), this yields $vu = uv$. Therefore, Proposition 6.1.4 yields that there exist a $t \in \mathfrak{A}^*$ and two nonnegative integers n and m such that $u = t^n$ and $v = t^m$. Consider this t and these n and m. We have $n \neq 0$ (since $t^n = u$ is nonempty) and $m \neq 0$ (since $t^m = v$ is nonempty), and the word t is nonempty (since $t^n = u$ is nonempty). Moreover, we have $n = 1$ [981]. Hence, $t^n = t^1 = t$, so that $u = t^n = t$ and $w = \underbrace{u}_{=t}\underbrace{v}_{=t^m} = tt^m = t^{m+1}$. We shall now prove that the word t is Lyndon.

Assume the contrary. Then, t is not Lyndon. Let q be the (lexicographically) smallest nonempty suffix of t. Then, Proposition 6.1.19(b) (applied to t and q instead of w and v) yields that there exists a nonempty $p \in \mathfrak{A}^*$ such that $t = pq$, $p \geq q$ and $pq \geq qp$ [982]. Consider this p. Since q is nonempty, we have $\ell(pq) > \ell(p)$, so that $\ell\left(\underbrace{u}_{=t=pq}\right) = \ell(pq) > \ell(p)$. From $pq \geq qp$, we obtain $qp \leq pq$. Thus, it is easy to see that $(qp)^{m+1} \leq (pq)^{m+1}$ [983].

We have $v = t^m$. Since $t = pq$, this rewrites as $v = (pq)^m$. Now,

$$q \underbrace{v}_{=(pq)^m} p = \underbrace{q(pq)^m}_{=(qp)^m q} p = (qp)^m qp = (qp)^{m+1} \leq (pq)^{m+1} = (pq)\left(\underbrace{pq}_{=t}\right)^m = (pq)\underbrace{t^m}_{=v} = (pq)v = pqv.$$

[980] *Proof.* Assume the contrary. Hence, any nonempty words u and v satisfying $w = uv$ satisfy $vu > uv$. In other words, w satisfies Assertion $\mathcal{D}$ of Theorem 6.1.20. Hence, w also satisfies Assertion $\mathcal{A}$ of Theorem 6.1.20 (since Theorem 6.1.20 yields the equivalence of these two assertions $\mathcal{D}$ and $\mathcal{A}$). In other words, w is a Lyndon word. This contradicts the knowledge that w is not a Lyndon word, qed.

[981] *Proof.* Assume the contrary. Hence, $n \neq 1$. Combined with $n \neq 0$, this leads to $n \geq 2$. As a consequence, $u = t^n$ can be rewritten as $u = tt^{n-1}$. The word t^{n-1+m} is nonempty (since t is nonempty and since $\underbrace{n}_{\geq 2} - 1 + \underbrace{m}_{\geq 0} \geq 2 - 1 + 0 = 1$). Now, $w = \underbrace{u}_{=tt^{n-1}}\underbrace{v}_{=t^m} = tt^{n-1}t^m = tt^{n-1+m}$. Also, $t^{n-1+m}t = t^{n-1+m+1} = tt^{n-1+m}$. Hence, (13.145.1) (applied to $u' = t$ and $v' = t^{n-1+m}$) yields $\ell(t) \geq \ell(u)$ (since t and t^{n-1+m} are nonempty). Since $u = t^n$, this rewrites as $\ell(t) \geq \ell(t^n) = \underbrace{n}_{\geq 2}\ell(t) \geq 2\ell(t)$, whence $\ell(t) = 0$, which contradicts the fact that t is nonempty. This contradiction shows that our assumption was wrong, qed.

[982] Notice that the variable p here is what has been called u in Proposition 6.1.19(b). (We had to rename it since the letter u is already in use.)

[983] *Proof.* We have $qp \leq pq$. Hence, Proposition 6.1.2(d) (applied to qp, $(qp)^m$, pq and $(pq)^m$ instead of a, b, c and d) yields that either we have $(qp)(qp)^m \leq (pq)(pq)^m$ or the word qp is a prefix of pq. In the first of these two cases, we are done (because in the first of these two cases, we have $(qp)(qp)^m \leq (pq)(pq)^m$ and thus $(qp)^{m+1} = (qp)(qp)^m \leq (pq)(pq)^m = (pq)^{m+1}$). Hence, we can WLOG assume that we are in the second of these two cases. Assume this. Then, the word qp is a prefix of pq. Since the word qp has the same length as pq (in fact, $\ell(qp) = \ell(q) + \ell(p) = \ell(p) + \ell(q) = \ell(pq)$), this yields that $qp = pq$, so that $\left(\underbrace{qp}_{=pq}\right)^{m+1} = (pq)^{m+1} \leq (pq)^{m+1}$, qed.

Since $w = \underbrace{u}_{=t=pq} v = pqv$, we can thus apply (13.145.1) to $u' = p$ and $v' = qv$. As a result, we obtain $\ell(p) \geq \ell(u)$. This contradicts $\ell(u) > \ell(p)$. This contradiction shows that our assumption (that t is not Lyndon) was wrong. Hence, t is Lyndon. Thus, w is a power of a Lyndon word (since $w = t^{m+1}$ is a power of t). Thus, Assertion $\mathcal{A}'$ is satisfied, so we have proven the implication $\mathcal{D}' \Longrightarrow \mathcal{A}'$.

Now we have proven both implications $\mathcal{A}' \Longrightarrow \mathcal{D}'$ and $\mathcal{D}' \Longrightarrow \mathcal{A}'$. Therefore, the equivalence $\mathcal{A}' \Longleftrightarrow \mathcal{D}'$ follows. Thus, Exercise 6.1.32(a) is solved.

(b) Consider the letter m and the alphabet $\mathfrak{A} \cup \{m\}$ defined in Assertion $\mathcal{F}''$. We notice that the lexicographic order on $\mathfrak{A}^*$ is the restriction of the lexicographic order on $(\mathfrak{A} \cup \{m\})^*$ to $\mathfrak{A}^*$. Therefore, when we have two words p and q in $\mathfrak{A}^*$, statements like "$p < q$" do not depend on whether we are regarding p and q as elements of $\mathfrak{A}^*$ or as elements of $(\mathfrak{A} \cup \{m\})^*$. It is easy to see that the one-letter word m satisfies

$$m > p \qquad \text{for every } p \in \mathfrak{A}^*. \tag{13.145.2}$$

[984]

We shall prove the implications $\mathcal{B}' \Longrightarrow \mathcal{E}'$, $\mathcal{C}' \Longrightarrow \mathcal{E}'$, $\mathcal{G}' \Longrightarrow \mathcal{H}'$, $\mathcal{E}' \Longrightarrow \mathcal{F}''$, $\mathcal{F}'' \Longrightarrow \mathcal{B}'$, $\mathcal{F}' \Longrightarrow \mathcal{C}'$, $\mathcal{B}' \Longrightarrow \mathcal{G}'$ and $\mathcal{H}' \Longrightarrow \mathcal{B}'$.

First of all, the implication $\mathcal{B}' \Longrightarrow \mathcal{E}'$ holds for obvious reasons (in fact, if two words u and v satisfying $w = uv$ satisfy $v \geq w$, then $v \geq u$ (because $v \geq w = uv \geq u$)). Also, the implication $\mathcal{C}' \Longrightarrow \mathcal{E}'$ holds for obvious reasons (in fact, if two words u and v satisfying $w = uv$ satisfy (v is a prefix of u), then (v is a prefix of w) (because v is a prefix of u, and u in turn is a prefix of $uv = w$)). The implication $\mathcal{G}' \Longrightarrow \mathcal{H}'$ is also trivially true.

Proof of the implication $\mathcal{E}' \Longrightarrow \mathcal{F}''$: Assume that Assertion $\mathcal{E}'$ holds.

Assume (for the sake of contradiction) that the word $wm \in (\mathfrak{A} \cup \{m\})^*$ is not a Lyndon word. Clearly, this word wm is nonempty. Let v' be the (lexicographically) smallest nonempty suffix of this word $wm \in (\mathfrak{A} \cup \{m\})^*$. Since wm is not a Lyndon word, we can apply Proposition 6.1.19(b) to $\mathfrak{A} \cup \{m\}$, wm and v' instead of $\mathfrak{A}$, w and v. As a result, we conclude that there exists a nonempty $u \in (\mathfrak{A} \cup \{m\})^*$ such that $wm = uv'$, $u \geq v'$ and $uv' \geq v'u$. Consider this u.

We know that v' is a suffix of wm. Thus, we must be in one of the following two cases (depending on whether this suffix begins before the suffix m of wm begins or afterwards):

Case 1: The word v' is a nonempty suffix of m. (Note that $v' = m$ is allowed.)

Case 2: The word v' has the form vm where v is a nonempty suffix of w.

Let us consider Case 1 first. In this case, the word v' is a nonempty suffix of m. Since the only nonempty suffix of m is m itself (because m is a one-letter word), this yields $v' = m$. Now, $wm = u \underbrace{v'}_{=m} = um$. Cancelling m from this equality, we obtain $w = u$, so that $u = w \in \mathfrak{A}^*$. Hence, $m > u$ (by (13.145.2), applied to $p = u$). This contradicts $u \geq v' = m$. Thus, we have obtained a contradiction in Case 1.

Let us now consider Case 2. In this case, the word v' has the form vm where v is a nonempty suffix of w. Consider this v. We have $wm = u \underbrace{v'}_{=vm} = uvm$. By cancelling m from this equality, we obtain $w = uv$. Thus, u and v are subwords of w, and therefore belong to $\mathfrak{A}^*$ (since $w \in \mathfrak{A}^*$). Moreover, u and v are nonempty. Hence, Assertion $\mathcal{E}'$ yields that either we have $v \geq u$ or the word v is a prefix of w. Since we cannot have $v \geq u$ (because if we had $v \geq u$, then we would have $v' = vm > v \geq u \geq v'$, which is absurd), we therefore must have that v is a prefix of w. In other words, there exists a $q \in \mathfrak{A}^*$ such that $w = vq$. Consider this q. We have $m > q$ (by (13.145.2), applied to $p = q$). Thus, $q \leq m$. Hence, Proposition 6.1.2(b) (applied to $\mathfrak{A} \cup \{m\}$, v, q and m instead of $\mathfrak{A}$, a, c and d) yields $vq \leq vm$. Therefore, $vm \geq vq = w$ (since $w = vq$), so that $v' = vm \geq w = uv > u$ (since v is nonempty). This contradicts $u \geq v'$. Thus, we have found a contradiction in Case 2.

[984] *Proof of (13.145.2):* Let $p \in \mathfrak{A}^*$. If p is empty, then (13.145.2) is obviously satisfied. Hence, for the rest of the proof of (13.145.2), we WLOG assume that p is nonempty. Then, p has a first letter, and we have (the first letter of the word p) $\in \mathfrak{A}$ (since $p \in \mathfrak{A}^*$). Thus,

$$\begin{aligned}(\text{the first letter of the word } p) &< m \qquad (\text{since } a < m \text{ for every } a \in \mathfrak{A}) \\ &= (\text{the first letter of the word } m)\,.\end{aligned}$$

Hence, $p < m$ (by the definition of the lexicographic order), that is, $m > p$. This proves (13.145.2).

We have therefore obtained a contradiction in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this shows that we always get a contradiction. Hence, our assumption (that the word $wm \in (\mathfrak{A} \cup \{m\})^*$ is not a Lyndon word) was false. Hence, the word $wm \in (\mathfrak{A} \cup \{m\})^*$ is a Lyndon word. That is, Assertion $\mathcal{F}''$ holds. Hence, we have proven the implication $\mathcal{E}' \Longrightarrow \mathcal{F}''$.

Proof of the implication $\mathcal{F}'' \Longrightarrow \mathcal{B}'$*:* Assume that Assertion $\mathcal{F}''$ holds. Thus, the word $wm \in (\mathfrak{A} \cup \{m\})^*$ is a Lyndon word.

Let u and v be nonempty words satisfying $w = uv$. We shall prove that either we have $v \geq w$ or the word v is a prefix of w.

Indeed, v is a suffix of w (since $w = uv$), so that vm is a suffix of wm. Clearly, vm is nonempty. Thus, Corollary 6.1.15 (applied to $\mathfrak{A} \cup \{m\}$, wm and vm instead of $\mathfrak{A}$, w and v) yields $vm \geq wm$. In other words, $wm \leq vm$. Hence, Proposition 6.1.2(e) (applied to $\mathfrak{A} \cup \{m\}$, w, m, v and m instead of $\mathfrak{A}$, a, b, c and d) yields that either we have $w \leq v$ or the word v is a prefix of w. In other words, either we have $v \geq w$ or the word v is a prefix of w.

Now, let us forget that we fixed u and v. We thus have proven that if u and v are nonempty words satisfying $w = uv$, then either we have $v \geq w$ or the word v is a prefix of w. In other words, Assertion $\mathcal{B}'$ holds. Hence, we have proven the implication $\mathcal{F}'' \Longrightarrow \mathcal{B}'$.

Proof of the implication $\mathcal{F}'' \Longrightarrow \mathcal{C}'$*:* Assume that Assertion $\mathcal{F}''$ holds. Thus, the word $wm \in (\mathfrak{A} \cup \{m\})^*$ is a Lyndon word.

Let u and v be nonempty words satisfying $w = uv$. We shall prove that either we have $v \geq u$ or the word v is a prefix of u.

Indeed, Proposition 6.1.14(b) (applied to $\mathfrak{A} \cup \{m\}$, wm and vm instead of $\mathfrak{A}$, w and v) yields $vm > u$ (since $\underbrace{w}_{=uv} m = uvm$, and since vm is nonempty). Hence, $vm \geq u = u\varnothing$, so that $u\varnothing \leq vm$. Thus, Proposition 6.1.2(e) (applied to $\mathfrak{A} \cup \{m\}$, u, $\varnothing$, v and m instead of $\mathfrak{A}$, a, b, c and d) yields that either we have $u \leq v$ or the word v is a prefix of u. In other words, either we have $v \geq u$ or the word v is a prefix of u.

Now, let us forget that we fixed u and v. We thus have proven that if u and v are nonempty words satisfying $w = uv$, then either we have $v \geq u$ or the word v is a prefix of u. In other words, Assertion $\mathcal{C}'$ holds. Hence, we have proven the implication $\mathcal{F}'' \Longrightarrow \mathcal{C}'$.

Proof of the implication $\mathcal{B}' \Longrightarrow \mathcal{G}'$*:* Assume that Assertion $\mathcal{B}'$ holds.

Let s be the longest suffix v of w satisfying $v < w$. (This is well-defined, because there exists a suffix v of w satisfying $v < w$ – namely, the empty word.) So we know that s is a suffix v of w satisfying $v < w$. In other words, s is a suffix of w and satisfies $s < w$. As a consequence, s is a proper suffix of w (because otherwise, s would be w, and this would contradict $s < w$). Hence, there exists a nonempty word $h \in \mathfrak{A}^*$ satisfying $w = hs$. Consider this h. Using Assertion $\mathcal{B}'$, it is easy to see that s is a prefix of w [985]. In other words, there exists a $g \in \mathfrak{A}^*$ such that $w = sg$. Consider this g.

We know that s is the longest suffix v of w satisfying $v < w$. Hence,

$$(\text{if } v \text{ is a suffix of } w \text{ satisfying } v < w, \text{ then } \ell(v) \leq \ell(s)). \tag{13.145.3}$$

There exists a nonnegative integer m such that h^m is a prefix of s (for example, the nonnegative integer $m = 0$). Consider the **maximal** such integer m [986]. Then, h^m is a prefix of s, but h^{m+1} is not a prefix of s. Since h^m is a prefix of s, there exists a word $q \in \mathfrak{A}^*$ such that $s = h^m q$. Consider this q. Clearly, $w = h \underbrace{s}_{=h^m q} = \underbrace{hh^m}_{=h^{m+1}} q = \underbrace{h^{m+1}}_{=h^m h} q = h^m hq$. Hence, $h^m hq = w = \underbrace{s}_{=h^m q} g = h^m qg$. Cancelling h^m from this

[985] *Proof.* Assume the contrary. Thus, s is not a prefix of w. Hence, s is nonempty. Therefore, Assertion $\mathcal{B}'$ (applied to $u = h$ and $v = s$) yields that either we have $s \geq w$ or the word s is a prefix of w. Since s is not a prefix of w, we must thus have $s \geq w$. But this contradicts $s < w$. This contradiction shows that our assumption was wrong, qed.

[986] This is well-defined, because of the following reason:

We have $\ell(h) \geq 1$ (since the word h is nonempty). Thus, for every $m \in \mathbb{N}$ satisfying $m > \ell(s)$, we have $\ell(h^m) = m \underbrace{\ell(h)}_{\geq 1} \geq m > \ell(s)$. In other words, for every $m \in \mathbb{N}$ satisfying $m > \ell(s)$, the word h^m is longer than s. Hence, for every $m \in \mathbb{N}$ satisfying $m > \ell(s)$, the word h^m cannot be a prefix of s. Thus, for every sufficiently high $m \in \mathbb{N}$, the word h^m cannot be a prefix of s.

We thus know the following:

- There exists a nonnegative integer m such that h^m is a prefix of s.
- For every sufficiently high $m \in \mathbb{N}$, the word h^m cannot be a prefix of s.

Consequently, there exists a **maximal** nonnegative integer m such that h^m is a prefix of s, qed.

equality, we obtain $hq = qg$. It is now easy to see that $h > q$ [987]. Hence, $q \leq h \leq hq = qg$. Thus, Proposition 6.1.2(g) (applied to q, h and g instead of a, b and c) yields that q is a prefix of h.

Next, we shall prove that the word h is Lyndon.

In fact, assume the contrary. Then, h is not Lyndon. Let v be the (lexicographically) smallest nonempty suffix of h. Then, Proposition 6.1.19(b) (applied to h instead of w) yields that there exists a nonempty $u \in \mathfrak{A}^*$ such that $h = uv$, $u \geq v$ and $uv \geq vu$. Consider this u. Since $w = \underbrace{h}_{=uv} s = uvs$, it is clear that the word vs is a suffix of w. If we had $vs < w$, then we could therefore obtain $\ell(vs) \leq \ell(s)$ (by (13.145.3), applied to vs instead of v), which would contradict $\ell(vs) = \underbrace{\ell(v)}_{\substack{>0 \\ (\text{since } v \text{ is nonempty})}} + \ell(s) > \ell(s)$. Thus, we cannot have $vs < w$. We thus have $vs \geq w = hs \geq h = uv$, so that $uv \leq vs$.

Recall that $s < w$. Hence, $vs \leq vw$ (by Proposition 6.1.2(b), applied to v, s and w instead of a, c and d). Now, $uv \geq vu$, so that $vu \leq uv \leq vs \leq v \underbrace{w}_{=hs} = v \underbrace{h}_{=uv} s = vuvs$. Hence, Proposition 6.1.2(g) (applied to vu, uv and vs instead of a, b and c) yields that vu is a prefix of uv. Since vu has the same length as uv (because $\ell(vu) = \ell(v) + \ell(u) = \ell(u) + \ell(v) = \ell(uv)$), this yields that $vu = uv$. Thus, the elements u and v of the monoid $\mathfrak{A}^*$ commute. Thus, the submonoid of $\mathfrak{A}^*$ generated by u and v is commutative. Since $h = uv$, the element h lies in this submonoid, and therefore the element h^m lies in it as well. Thus, h^m commutes with v (since this submonoid is commutative), i.e., we have $vh^m = h^m v$. Thus, $v \underbrace{s}_{=h^m q} = \underbrace{vh^m}_{=h^m v} q = h^m vq$. Thus, $h^m vq = vs \geq w = h \underbrace{s}_{=h^m q} = \underbrace{hh^m}_{=h^{m+1} = h^m h} q = h^m hq$, so that $h^m hq \leq h^m vq$. Hence, Proposition 6.1.2(c) (applied to h^m, hq and vq instead of a, c and d) yields $hq \leq vq$. But since q is a prefix of h, there exists a word $z \in \mathfrak{A}^*$ such that $h = qz$. Consider this z. We have

$$\begin{aligned} v \underbrace{qz}_{=h=uv} = \underbrace{vu}_{=uv=h} v = hv &\leq h \underbrace{vu}_{=uv=h=qz} \qquad (\text{since } hv \text{ is a prefix of } hvu) \\ &= hqz. \end{aligned}$$

Also, $\ell\left(\underbrace{h}_{=uv} q\right) = \ell(uvq) = \ell(u(vq)) = \underbrace{\ell(u)}_{\substack{>0 \\ (\text{since } u \text{ is nonempty})}} + \ell(vq) > \ell(vq)$, so that $\ell(vq) \leq \ell(hq)$. Hence, Proposition 6.1.2(f) (applied to vq, z, hq and z instead of a, b, c and d) yields $vq \leq hq$. Combined with $hq \leq vq$, this yields $vq = hq$. Hence, $\ell\left(\underbrace{vq}_{=hq}\right) = \ell(hq) > \ell(vq)$, which is absurd. This contradiction proves that our assumption is wrong. Thus, we have shown that the word h is Lyndon.

We now know that $h \in \mathfrak{A}^*$ is a Lyndon word, $m+1$ is a positive integer, and q is a prefix of h, and we have $w = h^{m+1} q$. Hence, there exists a Lyndon word $t \in \mathfrak{A}^*$, a positive integer ℓ and a prefix p of t (possibly empty) such that $w = t^\ell p$ (namely, $t = h$, $\ell = m+1$ and $p = q$). In other words, Assertion $\mathcal{G}'$ holds. This proves the implication $\mathcal{B}' \Longrightarrow \mathcal{G}'$.

We are now going to prove the implication $\mathcal{F}' \Longrightarrow \mathcal{B}'$; this implication will later be used in the proof of the implication $\mathcal{H}' \Longrightarrow \mathcal{B}'$.

Proof of the implication $\mathcal{F}' \Longrightarrow \mathcal{B}'$: Assume that Assertion $\mathcal{F}'$ holds. In other words, the word w is a prefix of a Lyndon word in $\mathfrak{A}^*$. Let z be this Lyndon word. Thus, w is a prefix of z. In other words, there exists a word $q \in \mathfrak{A}^*$ such that $z = wq$. Consider this q.

Let u and v be nonempty words satisfying $w = uv$. We are going to prove that either we have $v \geq w$ or the word v is a prefix of w.

[987] *Proof.* Assume the contrary. Then, $h \leq q$. Hence, $h \leq q \leq qg = hq$ (since $hq = qg$). Therefore, Proposition 6.1.2(g) (applied to h, q and q instead of a, b and c) yields that h is a prefix of q. In other words, there exists a word $r \in \mathfrak{A}^*$ such that $q = hr$. Consider this r. Now, $s = h^m \underbrace{q}_{=hr} = \underbrace{h^m h}_{=h^{m+1}} r = h^{m+1} r$, so that h^{m+1} is a prefix of s. This contradicts the fact that h^{m+1} is not a prefix of s. This contradiction proves that our assumption was wrong, qed.

We have $z = \underbrace{w}_{=uv} q = uvq$. Thus, Proposition 6.1.14(a) (applied to z and vq instead of w and v) yields $vq \geq z$ (since vq is nonempty (since v is nonempty)). Hence, $vq \geq z = wq$. In other words, $wq \leq vq$. Thus, Proposition 6.1.2(e) (applied to w, q, v and q instead of a, b, c and d) yields that either we have $w \leq v$ or the word v is a prefix of w. In other words, either we have $v \geq w$ or the word v is a prefix of w.

Now, forget that we fixed u and v. We thus have shown that if u and v are nonempty words satisfying $w = uv$, then either we have $v \geq w$ or the word v is a prefix of w. In other words, Assertion $\mathcal{B}'$ holds. Thus, the implication $\mathcal{F}' \Longrightarrow \mathcal{B}'$ is proven.

Proof of the implication $\mathcal{H}' \Longrightarrow \mathcal{B}'$: Assume that Assertion $\mathcal{H}'$ holds. In other words, there exists a Lyndon word $t \in \mathfrak{A}^*$, a nonnegative integer ℓ and a prefix p of t (possibly empty) such that $w = t^\ell p$. Consider this t, this ℓ and this p.

We are going to prove that for every $m \in \mathbb{N}$,

$$\text{(every suffix } s \text{ of } t^m p \text{ satisfies either } s \geq t^m p \text{ or } (\text{the word } s \text{ is a prefix of } t^m p)) . \tag{13.145.4}$$

Proof of (13.145.4): We will prove (13.145.4) by induction over m:

Induction base: Using the implication $\mathcal{F}' \Longrightarrow \mathcal{B}'$, it is easy to see that (13.145.4) holds for $m = 0$ [988]. This completes the induction base.

Induction step: Let M be a positive integer. Assume that (13.145.4) is proven for $m = M - 1$. We will now show that (13.145.4) holds for $m = M$.

Let r denote the word $t^{M-1}p$. It is easy to see that r is a prefix of $t^M p$ [989]. In other words, there exists a word $g \in \mathfrak{A}^*$ such that $t^M p = rg$. Consider this g.

Let s be a suffix of $t^M p$. We shall show that either $s \geq t^M p$ or $\left(\text{the word } s \text{ is a prefix of } t^M p\right)$.

In order to prove this, let us assume the contrary (for the sake of contradiction). Then, neither $s \geq t^M p$ nor $\left(\text{the word } s \text{ is a prefix of } t^M p\right)$. In other words, we have $s < t^M p$, and the word s is not a prefix of $t^M p$. If the word s was a prefix of r, then the word s would be a prefix of $t^M p$ (since r is a prefix of $t^M p$), which would contradict the fact that the word s is not a prefix of $t^M p$. Hence, the word s cannot be a prefix of r. In other words, the word s cannot be a prefix of $t^{M-1}p$ (since $r = t^{M-1}p$).

The word s is a suffix of $\underbrace{t^M}_{=tt^{M-1}} p = t \underbrace{t^{M-1}p}_{=r} = tr$. Therefore, we must be in one of the following two cases (depending on whether this suffix begins before the suffix r of tr begins or afterwards):

Case 1: The word s is a suffix of r. (Note that $s = r$ is allowed.)

Case 2: The word s has the form $s'r$ where s' is a nonempty suffix of t.

Let us consider Case 1 first. In this case, the word s is a suffix of r. In other words, the word s is a suffix of $t^{M-1}p$ (since $r = t^{M-1}p$). Hence, (13.145.4) (applied to $m = M - 1$) yields that either $s \geq t^{M-1}p$

[988] *Proof.* Assume that $m = 0$. Then, $t^m p = \underbrace{t^0}_{=\varnothing} p = \varnothing p = p$.

Let s be a suffix of $t^m p$. Then, s is a suffix of $t^m p = p$. In other words, there exists a word $g \in \mathfrak{A}^*$ satisfying $p = gs$. Consider this g.

We are going to prove that either $s \geq t^m p$ or (the word s is a prefix of $t^m p$). If the word s is empty, then this is obvious (because if the word s is empty, then the word s is a prefix of $t^m p$). Hence, we WLOG assume that the word s is nonempty. If the word g is empty, then it is also clear that either $s \geq t^m p$ or (the word s is a prefix of $t^m p$) (because if the word g is empty, then $g = \varnothing$ and thus $t^m p = p = \underbrace{g}_{=\varnothing} s = s$, so that the word s is a prefix of $t^m p$). Hence, we WLOG assume that the word g is nonempty.

But the word p is a prefix of a Lyndon word in $\mathfrak{A}^*$ (since p is a prefix of t, and since t is a Lyndon word in $\mathfrak{A}^*$). In other words, Assertion $\mathcal{F}'$ with w replaced by p is satisfied. Hence, Assertion $\mathcal{B}'$ with w replaced by p is satisfied as well (since we have already proven the implication $\mathcal{F}' \Longrightarrow \mathcal{B}'$). In other words,

$$\left(\begin{array}{c} \text{if } u \text{ and } v \text{ are nonempty words satisfying } p = uv, \text{ then} \\ \text{either we have } v \geq p \text{ or the word } v \text{ is a prefix of } p \end{array} \right) . \tag{13.145.5}$$

Since the words g and s are nonempty, we can apply (13.145.5) to $u = g$ and $v = s$. As a result, we obtain that either we have $s \geq p$ or the word s is a prefix of p. In other words, either $s \geq p$ or (the word s is a prefix of p). In other words, either $s \geq t^m p$ or (the word s is a prefix of $t^m p$) (since $t^m p = p$). This proves (13.145.4).

[989] *Proof.* There exists a word $q \in \mathfrak{A}^*$ such that $t = pq$ (since p is a prefix of t). Consider this q. We have $\underbrace{t^M}_{=t^{M-1}t} p = t^{M-1} \underbrace{t}_{=pq} p = \underbrace{t^{M-1}p}_{=r} qp = rqp = r(qp)$. Hence, r is a prefix of $t^M p$, qed.

or $\left(\text{the word } s \text{ is a prefix of } t^{M-1}p\right)$ (since (13.145.4) holds for $m = M-1$). Since the word s cannot be a prefix of $t^{M-1}p$, we thus must have $s \geq t^{M-1}p$. Thus, $t^{M-1}p \leq s < t^M p = rg$. Hence, $r = t^{M-1}p \leq s < rg$. Therefore, Proposition 6.1.2(g) (applied to r, s and g instead of a, b and c) yields that r is a prefix of s. Since $\ell(r) \geq \ell(s)$ (because s is a suffix of r), this can only hold if $r = s$. We thus have $r = s$. Thus, $s = r$, so that s is a prefix of $s = r$. This contradicts the fact that the word s cannot be a prefix of r. Thus, we have found a contradiction in Case 1.

Let us now consider Case 2. In this case, the word s has the form $s'r$ where s' is a nonempty suffix of t. Consider this s'. Corollary 6.1.15 (applied to t and s' instead of w and v) yields $s' \geq t$. But s' is a suffix of t, so that $\ell(s') \leq \ell(t)$. Also, $s = s'r$, so that $s'r = s < t^M p = tr$. Hence, Proposition 6.1.2(f) (applied to s', r, t and r instead of a, b, c and d) yields that $s' \leq t$. Combined with $s' \geq t$, this yields $s' = t$. Hence, $s = \underbrace{s'}_{=t} r = t^M p$ (since $t^M p = tr$), which contradicts the fact that the word s is not a prefix of $t^M p$. Thus, we have found a contradiction in Case 2.

We have thus obtained a contradiction in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this shows that we always get a contradiction. This completes the proof that either $s \geq t^M p$ or $\left(\text{the word } s \text{ is a prefix of } t^M p\right)$.

Now, forget that we fixed s. We thus have shown that every suffix s of $t^M p$ satisfies either $s \geq t^M p$ or $\left(\text{the word } s \text{ is a prefix of } t^M p\right)$. In other words, (13.145.4) holds for $m = M$. This completes the induction step, and thus (13.145.4) is proven by induction.

Now, let u and v be nonempty words satisfying $w = uv$. Then, v is a suffix of $w = t^\ell p$. Hence, (13.145.4) (applied to $m = \ell$ and $s = v$) yields that either $v \geq t^\ell p$ or $\left(\text{the word } v \text{ is a prefix of } t^\ell p\right)$. In other words, either $v \geq w$ or (the word v is a prefix of w) (since $w = t^\ell p$). In other words, either we have $v \geq w$ or the word v is a prefix of w.

Now, forget that we fixed u and v. We thus have shown that if u and v are nonempty words satisfying $w = uv$, then either we have $v \geq w$ or the word v is a prefix of w. In other words, Assertion $\mathcal{B}'$ holds. Thus, the implication $\mathcal{H}' \Longrightarrow \mathcal{B}'$ is proven.

We have thus proven the implications $\mathcal{B}' \Longrightarrow \mathcal{E}'$, $\mathcal{C}' \Longrightarrow \mathcal{E}'$, $\mathcal{G}' \Longrightarrow \mathcal{H}'$, $\mathcal{E}' \Longrightarrow \mathcal{F}''$, $\mathcal{F}'' \Longrightarrow \mathcal{B}'$, $\mathcal{F}' \Longrightarrow \mathcal{C}'$, $\mathcal{B}' \Longrightarrow \mathcal{G}'$ and $\mathcal{H}' \Longrightarrow \mathcal{B}'$. Combined, these yield the equivalence $\mathcal{B}' \Longleftrightarrow \mathcal{C}' \Longleftrightarrow \mathcal{E}' \Longleftrightarrow \mathcal{F}'' \Longleftrightarrow \mathcal{G}' \Longleftrightarrow \mathcal{H}'$. This solves Exercise 6.1.32(b).

(c) The implication $\mathcal{F}' \Longrightarrow \mathcal{B}'$ has already been proven in our solution of Exercise 6.1.32(b). Hence, Exercise 6.1.32(c) is solved.

(d) Assume that Assertion $\mathcal{D}'$ holds. Then, Assertion $\mathcal{A}'$ holds as well (because of the equivalence $\mathcal{A}' \Longleftrightarrow \mathcal{D}'$). In other words, the word w is a power of a Lyndon word. In other words, there exist a Lyndon word $z \in \mathfrak{A}^*$ and a nonnegative integer m such that $w = z^m$. Consider these z and m. There exists a Lyndon word $t \in \mathfrak{A}^*$, a nonnegative integer ℓ and a prefix p of t (possibly empty) such that $w = t^\ell p$ (namely, $t = z$, $\ell = m$ and $p = \varnothing$). In other words, Assertion $\mathcal{H}'$ holds. Since Assertion $\mathcal{H}'$ is equivalent to Assertion $\mathcal{B}'$ (because of the equivalence $\mathcal{B}' \Longleftrightarrow \mathcal{C}' \Longleftrightarrow \mathcal{E}' \Longleftrightarrow \mathcal{F}'' \Longleftrightarrow \mathcal{G}' \Longleftrightarrow \mathcal{H}'$), this yields that Assertion $\mathcal{B}'$ holds. Thus, the implication $\mathcal{D}' \Longrightarrow \mathcal{B}'$ is proven.

(e) Assume that there exists a letter $\mu \in \mathfrak{A}$ such that ($\mu > a$ for every letter a of w). Consider this μ. We need to prove that the equivalence $\mathcal{F}' \Longleftrightarrow \mathcal{F}''$ holds.

Combining the implication $\mathcal{F}' \Longrightarrow \mathcal{B}'$ (which has already been proven) and the implication $\mathcal{B}' \Longrightarrow \mathcal{F}''$ (which follows from the equivalence $\mathcal{B}' \Longleftrightarrow \mathcal{C}' \Longleftrightarrow \mathcal{E}' \Longleftrightarrow \mathcal{F}'' \Longleftrightarrow \mathcal{G}' \Longleftrightarrow \mathcal{H}'$ proven above), we obtain the implication $\mathcal{F}' \Longrightarrow \mathcal{F}''$. Thus, in order to prove the equivalence $\mathcal{F}' \Longleftrightarrow \mathcal{F}''$, it is enough to verify the implication $\mathcal{F}'' \Longrightarrow \mathcal{F}'$. Let us do this now.

Assume that Assertion $\mathcal{F}''$ holds. Let $\mathfrak{B}$ denote the alphabet consisting of all letters that appear in w. Clearly, $\mathfrak{B}$ is a subalphabet of $\mathfrak{A}$, and we have $w \in \mathfrak{B}^*$. Moreover, we have $\mu > a$ for every letter a of w. Therefore, $\mu > a$ for every $a \in \mathfrak{B}$ (because the elements of $\mathfrak{B}$ are precisely the letters of w). In other words, $a < \mu$ for every $a \in \mathfrak{B}$. As a consequence, $\mu \notin \mathfrak{B}$; that is, μ is an object not in the alphabet $\mathfrak{B}$.

We know that Assertion $\mathcal{F}''$ holds. Due to the implication $\mathcal{F}'' \Longrightarrow \mathcal{B}'$ (which follows from the equivalence $\mathcal{B}' \Longleftrightarrow \mathcal{C}' \Longleftrightarrow \mathcal{E}' \Longleftrightarrow \mathcal{F}'' \Longleftrightarrow \mathcal{G}' \Longleftrightarrow \mathcal{H}'$ proven above), this yields that Assertion $\mathcal{B}'$ holds. Thus, Assertion $\mathcal{B}'$ with $\mathfrak{A}$ replaced by $\mathfrak{B}$ holds as well (since the Assertion $\mathcal{B}'$ does not change if we extend our alphabet). Due to the implication $\mathcal{B}' \Longrightarrow \mathcal{F}''$ (which follows from the equivalence $\mathcal{B}' \Longleftrightarrow \mathcal{C}' \Longleftrightarrow \mathcal{E}' \Longleftrightarrow \mathcal{F}'' \Longleftrightarrow \mathcal{G}' \Longleftrightarrow \mathcal{H}'$ proven above), this yields that Assertion $\mathcal{F}''$ with $\mathfrak{A}$ replaced by $\mathfrak{B}$ holds as well. Thus, we can apply Assertion $\mathcal{F}''$ with $\mathfrak{A}$ replaced by $\mathfrak{B}$ to $m = \mu$ (because μ is an object not in the alphabet $\mathfrak{B}$, and the total order on $\mathfrak{A}$ satisfies ($a < \mu$ for every $a \in \mathfrak{B}$)). As a result, we conclude that the word $w\mu \in (\mathfrak{B} \cup \{\mu\})^*$ is a Lyndon word. Since $\mathfrak{B} \cup \{\mu\} \subset \mathfrak{A}$ (because $\mathfrak{B} \subset \mathfrak{A}$ and $\mu \in \mathfrak{A}$), we have $w\mu \in \left(\underbrace{\mathfrak{B} \cup \{\mu\}}_{\subset \mathfrak{A}}\right)^* \subset \mathfrak{A}^*$, and thus $w\mu \in \mathfrak{A}^*$ is a Lyndon word. Of course, the word w is a prefix of $w\mu$. As a consequence, the word w is a prefix of a Lyndon word in $\mathfrak{A}^*$ (namely, of the word $w\mu$). In other words, Assertion $\mathcal{F}'$ holds. This proves the implication $\mathcal{F}'' \Longrightarrow \mathcal{F}'$. Thus, the solution of Exercise 6.1.32(e) is complete.

(f) Assume that there exists a letter $\mu \in \mathfrak{A}$ such that ($\mu > a$ for some letter a of w). Consider this μ. We need to prove that the equivalence $\mathcal{F}' \Longleftrightarrow \mathcal{F}''$ holds.

Just as in our solution of Exercise 6.1.32(e) above, we can see that it is enough to verify the implication $\mathcal{F}'' \Longrightarrow \mathcal{F}'$. Let us do this now.

Assume that Assertion $\mathcal{F}''$ holds. Due to the implication $\mathcal{F}'' \Longrightarrow \mathcal{B}'$ (which follows from the equivalence $\mathcal{B}' \Longleftrightarrow \mathcal{C}' \Longleftrightarrow \mathcal{E}' \Longleftrightarrow \mathcal{F}'' \Longleftrightarrow \mathcal{G}' \Longleftrightarrow \mathcal{H}'$ proven above), this yields that Assertion $\mathcal{B}'$ holds.

Let β be the highest letter of the word $w\mu \in \mathfrak{A}^*$ (the concatenation of the word w with the one-letter word μ). The word $w\beta^{\ell(w)}$ is clearly nonempty (since w is nonempty). We shall now prove that the word $w\beta^{\ell(w)}$ is Lyndon.

Indeed, assume the contrary. Thus, $w\beta^{\ell(w)}$ is not Lyndon. Let v denote the (lexicographically) smallest nonempty suffix of $w\beta^{\ell(w)}$. Then, Proposition 6.1.19(b) (applied to $w\beta^{\ell(w)}$ instead of w) yields that there exists a nonempty $u \in \mathfrak{A}^*$ such that $w\beta^{\ell(w)} = uv$, $u \geq v$ and $uv \geq vu$.

Let f be the first letter of the word w (this is well-defined since w is nonempty). Then, we can write w in the form $w = fs$ for some word $s \in \mathfrak{A}^*$. Consider this s.

We know that $\mu > a$ for some letter a of w. Consider this a. We also know that β is the highest letter of the word $w\mu$. Thus, β is $\geq$ to every letter of the word $w\mu$. In particular, this yields that $\beta \geq \mu$ (since μ is a letter of the word $w\mu$), so that $\beta \geq \mu > a$. But it is fairly easy to see (using the fact that Assertion $\mathcal{B}'$ holds) that $a \geq f$ [990]. Hence, $\beta > a \geq f$.

The word v is a proper suffix of $w\beta^{\ell(w)}$ (since $w\beta^{\ell(w)} = uv$ and since u is nonempty) and is nonempty. Hence, v is a nonempty proper suffix of $w\beta^{\ell(w)}$. Therefore, we must be in one of the following two cases (depending on whether this suffix begins before the suffix $\beta^{\ell(w)}$ of $w\beta^{\ell(w)}$ begins or afterwards):

Case 1: The word v is a nonempty suffix of $\beta^{\ell(w)}$. (Note that $v = \beta^{\ell(w)}$ is allowed.)

Case 2: The word v has the form $q\beta^{\ell(w)}$ where q is a nonempty proper suffix of w.

Let us first consider Case 1. In this case, the word v is a nonempty suffix of $\beta^{\ell(w)}$. Thus, v has the form β^i for some $i \in \{0, 1, \ldots, \ell(w)\}$. Consider this i. We have $v = \beta^i$. Thus, $i \neq 0$ (since v is nonempty). Hence, (the first letter of v) $= \beta$. But since the word w is nonempty, we have

$$\left(\text{the first letter of } w\beta^{\ell(w)}\right) = (\text{the first letter of } w) = f$$

(since f was defined to be the first letter of w). Now,

$$(\text{the first letter of } v) = \beta > f = \left(\text{the first letter of } w\beta^{\ell(w)}\right).$$

By the definition of lexicographic order, this shows that $v > w\beta^{\ell(w)}$. But this contradicts $w\beta^{\ell(w)} = uv \geq vu \geq v$. Hence, we have found a contradiction in Case 1.

[990] *Proof.* Assume the contrary. Thus, $a < f$.

Since a is a letter of w, the word w must have a suffix which begins with the letter a. Let p be this suffix. Then, there exists a word $q \in \mathfrak{A}^*$ such that $w = qp$ (since p is a suffix of w). Consider this q. The word p is nonempty (since it begins with a). Since the word p begins with the letter a, we have

$$(\text{the first letter of } p) = a < f = (\text{the first letter of } w)\,. \tag{13.145.6}$$

By the definition of the lexicographic order, this shows that $p < w$. Hence, $p \neq w$. Now, the word q is nonempty (since otherwise, we would have $q = \varnothing$ and thus $w = \underbrace{q}_{=\varnothing} p = p$, contradicting $p \neq w$). Hence, applying Assertion $\mathcal{B}'$ to q and p instead of u and v, we conclude that either we have $p \geq w$ or the word p is a prefix of w. Since $p \geq w$ is impossible (because $p < w$), this yields that the word p is a prefix of w. Since p is nonempty, this shows that p is a nonempty prefix of w. But this yields that

$$(\text{the first letter of } p) = (\text{the first letter of } w)\,;$$

this contradicts (13.145.6). This contradiction proves that our assumption was wrong, qed.

Let us now consider Case 2. In this case, the word v has the form $q\beta^{\ell(w)}$ where q is a nonempty proper suffix of w. Consider this q. Notice that $\ell(q) < \ell(w)$ (since q is a proper suffix of w), so that $\ell(w) > \ell(q)$.

Since q is a proper suffix of w, there exists a nonempty word $u \in \mathfrak{A}^*$ such that $w = uq$. Consider this u. Recall that Assertion $\mathcal{B}'$ holds. Applying this Assertion $\mathcal{B}'$ to q instead of v, we conclude that either we have $q \geq w$ or the word q is a prefix of w. If the word q is not a prefix of w, then it is very easy to derive a contradiction[991]. Hence, the word q must be a prefix of w. In other words, there exists a word $g \in \mathfrak{A}^*$ such that $w = qg$. Consider this g. Notice that $\ell\left(\underbrace{w}_{=qg}\right) = \ell(qg) = \underbrace{\ell(q)}_{\substack{>0 \\ (\text{since } q \text{ is nonempty})}} + \ell(g) > \ell(g)$, so that $\ell\left(\beta^{\ell(w)}\right) = \ell(w) > \ell(g)$. In other words, the word $\beta^{\ell(w)}$ is longer than g. It is now easy to see that $\beta^{\ell(w)} \geq g$ [992]. In other words, $g \leq \beta^{\ell(w)}$. Hence, Proposition 6.1.2(b) (applied to q, g and $\beta^{\ell(w)}$ instead of a, c and d) yields $qg \leq q\beta^{\ell(w)}$, so that $w = qg \leq q\beta^{\ell(w)} = v$ (since $v = q\beta^{\ell(w)}$). Thus, $v \geq w$, so that $u \geq v \geq w$.

But $v = q\beta^{\ell(w)}$, so that $w\beta^{\ell(w)} = u \underbrace{v}_{=q\beta^{\ell(w)}} = uq\beta^{\ell(w)}$. Cancelling $\beta^{\ell(w)}$ from this equation, we obtain $w = uq$. Thus, $u \leq uq = w$. Since $u \neq w$ [993], this becomes $u < w$. This contradicts $u \geq w$. Hence, we have found a contradiction in Case 2.

We have now obtained a contradiction in each of our two Cases 1 and 2. Since these two Cases cover all possibilities, this yields that we always obtain a contradiction. Thus, our assumption was wrong, and we conclude that the word $w\beta^{\ell(w)}$ is Lyndon. Hence, w is a prefix of a Lyndon word in $\mathfrak{A}^*$ (because w is a prefix of the word $w\beta^{\ell(w)}$). In other words, Assertion $\mathcal{F}'$ holds. This proves the implication $\mathcal{F}'' \Longrightarrow \mathcal{F}'$. This solves Exercise 6.1.32(f).

Remark: Of course, for a letter $\mu \in \mathfrak{A}$, if we have ($\mu > a$ for every letter a of w), then we also have ($\mu > a$ for some letter a of w) (since w is nonempty and thus has at least one letter). Hence, Exercise 6.1.32(e) is a particular case of Exercise 6.1.32(f).

13.146. **Solution to Exercise 6.1.33.** *Solution to Exercise 6.1.33.*

(a) If we replace the word "total" by "partial" throughout the proof of Proposition 6.1.2, then the resulting argument can be used in the partial-order setting to prove Proposition 6.1.2 with "a total order" replaced by "a partial order". Hence, Proposition 6.1.2 holds in the partial-order setting, as long as one replaces "a total order" by "a partial order" in part (a) of this Proposition. This solves Exercise 6.1.33(a).

[991] *Proof.* Assume that the word q is not a prefix of w. Then, we have $q \geq w$ (since we know that either we have $q \geq w$ or the word q is a prefix of w). In other words, $w \leq q$. Hence, Proposition 6.1.2(d) (applied to w, $\beta^{\ell(w)}$, q and $\beta^{\ell(w)}$ instead of a, b, c and d) yields that either we have $w\beta^{\ell(w)} \leq q\beta^{\ell(w)}$ or the word w is a prefix of q. Since the word w is not a prefix of q (because $\ell(w) > \ell(q)$), this yields that we have $w\beta^{\ell(w)} \leq q\beta^{\ell(w)}$. Since $\ell\left(w\beta^{\ell(w)}\right) = \underbrace{\ell(w)}_{>\ell(q)} + \ell\left(\beta^{\ell(w)}\right) > \ell(q) + \ell\left(\beta^{\ell(w)}\right) = \ell\left(q\beta^{\ell(w)}\right)$, this shows that $w\beta^{\ell(w)} < q\beta^{\ell(w)} = v$ (because $v = q\beta^{\ell(w)}$). Hence, $v > w\beta^{\ell(w)} = uv \geq vu \geq v$, which is a contradiction, qed.

[992] *Proof.* Assume the contrary. Then, $\beta^{\ell(w)} < g$. By the definition of the lexicographic order, this yields that

$$\begin{aligned}&\textbf{either } \text{there exists an } i \in \left\{1, 2, \ldots, \min\left\{\ell\left(\beta^{\ell(w)}\right), \ell(g)\right\}\right\} \\ &\qquad \text{such that } \left(\left(\beta^{\ell(w)}\right)_i < g_i, \text{ and every } j \in \{1, 2, \ldots, i-1\} \text{ satisfies } \left(\beta^{\ell(w)}\right)_j = g_j\right), \\ &\textbf{or } \text{the word } \beta^{\ell(w)} \text{ is a prefix of } g.\end{aligned}$$

Since the word $\beta^{\ell(w)}$ cannot be a prefix of g (because the word $\beta^{\ell(w)}$ is longer than g), this yields that there exists an $i \in \left\{1, 2, \ldots, \min\left\{\ell\left(\beta^{\ell(w)}\right), \ell(g)\right\}\right\}$ such that $\left(\left(\beta^{\ell(w)}\right)_i < g_i, \text{ and every } j \in \{1, 2, \ldots, i-1\} \text{ satisfies } \left(\beta^{\ell(w)}\right)_j = g_j\right)$. Consider this i. We have $\left(\beta^{\ell(w)}\right)_i = \beta$, so that $\beta = \left(\beta^{\ell(w)}\right)_i < g_i$.

But g is a suffix of w (since $w = qg$), and thus every letter of g is a letter of w. In particular, g_i is a letter of w. Hence, g_i is a letter of $w\mu$ as well (since every letter of w is a letter of $w\mu$ (because w is a prefix of $w\mu$)). Since β is the highest letter of $w\mu$, this yields $\beta \geq g_i$. But this contradicts $\beta < g_i$. This contradiction proves that our assumption was false, qed.

[993] *Proof.* Assume the contrary. Then, $u = w$. Hence, $u\varnothing = u = w = uq$. Cancelling u from this equation, we obtain $\varnothing = q$. Hence, the word q is empty. This contradicts the fact that q is nonempty. This contradiction shows that our assumption was wrong, qed.

(b) Let us work in the partial-order setting. Let $a, b, c, d \in \mathfrak{A}^*$ be four words such that the words ab and cd are comparable. We need to prove that the words a and c are comparable.

The words ab and cd are comparable. In other words, we have either $ab \leq cd$ or $ab \geq cd$. In other words, we have either $ab \leq cd$ or $cd \leq ab$. We can WLOG assume that $ab \leq cd$ (since otherwise, we can achieve $ab \leq cd$ by switching a and b with c and d, respectively). Assume this. We know (from Exercise 6.1.33(a)) that Proposition 6.1.2 holds in the partial-order setting, as long as one replaces "a total order" by "a partial order" in part (a) of this Proposition. In particular, Proposition 6.1.2(e) holds in the partial-order setting. Applying Proposition 6.1.2(e), we thus conclude that either we have $a \leq c$ or the word c is a prefix of a. Thus, either we have $a \leq c$ or we have $c \leq a$ (because if c is a prefix of a, then $c \leq a$). In other words, either we have $a \leq c$ or we have $a \geq c$. In other words, the words a and c are comparable. This solves Exercise 6.1.33(b).

(c) Recall (from Exercise 6.1.33(a)) that Proposition 6.1.2 holds in the partial-order setting, as long as one replaces "a total order" by "a partial order" in part (a) of this Proposition.

Proposition 6.1.4 holds in the partial-order setting, because its proof applies verbatim in this setting.

Proposition 6.1.5 holds in the partial-order setting, because its proof applies verbatim in this setting.

The proof of Corollary 6.1.6 given above is no longer applicable in the partial-order setting. However, the alternative proof of Corollary 6.1.6 given in the solution to Exercise 6.1.7 does apply verbatim in the partial-order setting. Thus, Corollary 6.1.6 holds in the partial-order setting.

Corollary 6.1.8 holds in the partial-order setting, because its proof applies verbatim in this setting.

Exercise 6.1.9 and Exercise 6.1.10 hold in the partial-order setting, because their solutions apply verbatim in this setting.

Exercise 6.1.11 and Exercise 6.1.12 hold in the partial-order setting, because their solutions apply verbatim in this setting.

Proposition 6.1.14 holds in the partial-order setting, because its proof applies verbatim in this setting.

Corollary 6.1.15 holds in the partial-order setting, because its proof applies verbatim in this setting.

Proposition 6.1.16 holds in the partial-order setting, because its proof applies verbatim in this setting.

Corollary 6.1.17 holds in the partial-order setting, because its proof applies verbatim in this setting.

Our proof of Proposition 6.1.18 does not directly apply in the partial-order setting; however, it can be tweaked so that it does:

Proof of Proposition 6.1.18 in the partial-order setting. If the words u and v are incomparable, then Proposition 6.1.18 is easily seen to hold[994]. Hence, for the rest of this proof, we can WLOG assume that the words u and v are comparable. Assume this.

The words u and v are comparable. In other words, we have either $u < v$ or $u = v$ or $u > v$. From here, we can proceed as in our proof of Proposition 6.1.18 in the total-order setting. Proposition 6.1.18 is thus proven in the partial-order setting. □

Exercise 6.1.21(a) holds in the partial-order setting, because its solution applies verbatim in this setting.

The proof of Theorem 6.1.20 we gave (using Proposition 6.1.19) does not work in the partial-order setting[995]. However, the alternative proof of Theorem 6.1.20 given in Exercise 6.1.21(b) does apply verbatim in the partial-order setting. Thus, Theorem 6.1.20 holds in the partial-order setting.

Exercise 6.1.23 and Exercise 6.1.24 hold in the partial-order setting, because their solutions apply verbatim in this setting.

Exercise 6.1.31(a) and Exercise 6.1.31(b) hold in the partial-order setting, because their solutions apply verbatim in this setting.

Exercise 6.1.33(c) is thus solved.

[994] *Proof.* Assume that u and v are incomparable. If the words uv and vu were comparable, then the words u and v would also be comparable (by Exercise 6.1.33(b), applied to $a = u$, $b = v$, $c = v$ and $d = u$), which would contradict the fact that u and v are incomparable. Hence, the words uv and vu are incomparable. Thus, we cannot have $uv \geq vu$. But we cannot have $u \geq v$ either (since u and v are incomparable). Thus, neither $u \geq v$ nor $uv \geq vu$ holds. Hence, $u \geq v$ if and only if $uv \geq vu$; therefore, Proposition 6.1.18 holds, qed.

[995] One might try tweaking Proposition 6.1.19 for the partial-order setting by replacing "the (lexicographically) smallest nonempty suffix" by "a nonempty suffix which is (lexicographically) minimal among the nonempty suffices", and by replacing "$u \geq v$ and $uv \geq vu$" by "neither $u < v$ nor $uv < vu$". But this still would not hold. For example, if w is the word $XX12$ over the partially ordered alphabet $\{X, 1, 2\}$ with relation $1 < 2$, then the nonempty suffix $X12$ is lexicographically minimal among such suffixes, but we do have $X < X12$. (At least $uv < vu$ does not hold indeed.)

[*Remark:* In the above solution of Exercise 6.1.33(c), we have used the results of Exercise 6.1.21(b) and Exercise 6.1.7. This is the main reason why the latter two exercises have been written. However, there is a way to avoid them and still prove that Theorem 6.1.20 and Corollary 6.1.6 hold in the partial-order setting. This uses a trick, which we shall now explain.

First, a definition:

Definition 13.146.1. Let P be a poset.

(a) A poset Q is said to be an *extension* of P if and only if the following two statements hold:
- We have $Q = P$ as sets.
- Any two elements a and b of P satisfying $a \leq b$ in P satisfy $a \leq b$ in Q.

(b) An extension Q of P is called a *linear extension* of P if and only if the poset Q is totally ordered.[996]

The following fact about extensions of posets is well-known:

Proposition 13.146.2. *Let P be a finite poset.*

(a) *If a and b are two incomparable elements of P, then there exists an extension Q of P such that we have $a < b$ in Q.*

(b) *If a and b are two elements of P which don't satisfy $a \geq b$, then there exists an extension Q of P such that we have $a < b$ in Q.*

(c) *There exists a linear extension of P.*

(d) *If a and b are two elements of P which don't satisfy $a \geq b$, then there exists a linear extension Q of P such that we have $a < b$ in Q.*

(Actually, the requirement that P be finite in Proposition 13.146.2 can be dropped if you accept Zorn's lemma, but we do not need this generality.)

We can now apply this all to alphabets. In the partial-order setting, alphabets are posets, and so it makes sense to speak of an extension of an alphabet. We notice the following fact:

Proposition 13.146.3. *Let $\mathfrak{A}$ be a finite poset.*

(a) *If $\mathfrak{B}$ is an extension of the poset $\mathfrak{A}$, then $\mathfrak{B}^*$ is an extension of the poset $\mathfrak{A}^*$.*

(b) *Let $u \in \mathfrak{A}^*$ and $v \in \mathfrak{A}^*$ be two words. Then, $u < v$ holds in $\mathfrak{A}^*$ if and only if we have*

$$(u < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}) .$$

Proof of Proposition 13.146.3. (a) Let $\mathfrak{B}$ be an extension of the poset $\mathfrak{A}$. Then, by the definition of an "extension", we see that:

- We have $\mathfrak{B} = \mathfrak{A}$ as sets.
- Any two elements a and b of $\mathfrak{A}$ satisfying $a \leq b$ in $\mathfrak{A}$ satisfy $a \leq b$ in $\mathfrak{B}$.

Now, it is clear that $\mathfrak{B}^* = \mathfrak{A}^*$ as sets (since $\mathfrak{B} = \mathfrak{A}$ as sets). Also, any two elements a and b of $\mathfrak{A}^*$ satisfying $a \leq b$ in $\mathfrak{A}^*$ satisfy $a \leq b$ in $\mathfrak{B}^*$ [997]. Consequently, $\mathfrak{B}^*$ is an extension of the poset $\mathfrak{A}^*$. This proves Proposition 13.146.3(a).

[996] This notion of a linear extension is identical to the one used in Theorem 5.2.11, except that we don't require P to be finite here.

[997] *Proof.* Let u and v be two elements of $\mathfrak{A}^*$ satisfying $u \leq v$ in $\mathfrak{A}^*$. We are going to prove that $u \leq v$ in $\mathfrak{B}^*$.

According to the definition of the relation $\leq$ on $\mathfrak{A}^*$, we have that

$$\begin{aligned} &\textbf{either } \text{there exists an } i \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\} \\ &\qquad \text{such that } (u_i < v_i \text{ in } \mathfrak{A}, \text{ and every } j \in \{1, 2, \ldots, i-1\} \text{ satisfies } u_j = v_j), \\ &\textbf{or } \text{the word } u \text{ is a prefix of } v \end{aligned}$$

(because $u \leq v$ in $\mathfrak{A}$). In other words, we must be in one of the following two cases:

Case 1: There exists an $i \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$ such that ($u_i < v_i$ in $\mathfrak{A}$, and every $j \in \{1, 2, \ldots, i-1\}$ satisfies $u_j = v_j$).

Case 2: The word u is a prefix of v.

Let us first consider Case 1. In this case, there exists an $i \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$ such that ($u_i < v_i$ in $\mathfrak{A}$, and every $j \in \{1, 2, \ldots, i-1\}$ satisfies $u_j = v_j$). Let i' be this i. Thus, $i' \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$ satisfies ($u_{i'} < v_{i'}$ in $\mathfrak{A}$, and every $j \in \{1, 2, \ldots, i'-1\}$ satisfies $u_j = v_j$).

We have $u_{i'} < v_{i'}$ in $\mathfrak{A}$; thus, $u_{i'} \leq v_{i'}$ in $\mathfrak{A}$ and $u_{i'} \neq v_{i'}$.

Recall that any two elements a and b of $\mathfrak{A}$ satisfying $a \leq b$ in $\mathfrak{A}$ satisfy $a \leq b$ in $\mathfrak{B}$. Applied to $a = u_{i'}$ and $b = v_{i'}$, this yields that $u_{i'} \leq v_{i'}$ in $\mathfrak{B}$ (since $u_{i'} \leq v_{i'}$ in $\mathfrak{A}$). Combined with $u_{i'} \neq v_{i'}$, this yields $u_{i'} < v_{i'}$ in $\mathfrak{B}$. Thus, we have ($u_{i'} < v_{i'}$ in $\mathfrak{B}$, and every $j \in \{1, 2, \ldots, i'-1\}$ satisfies $u_j = v_j$). Consequently, there exists an $i \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$

(b) It is easy to prove the logical implication

$$\left(u < v \text{ in } \mathfrak{A}^*\right) \Longrightarrow \left(u < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}\right) \tag{13.146.1}$$

[998]. We shall now focus on proving the implication

$$\left(u < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}\right) \Longrightarrow \left(u < v \text{ in } \mathfrak{A}^*\right). \tag{13.146.2}$$

Proof of (13.146.1): Assume that

$$u < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}. \tag{13.146.3}$$

We need to show that $u < v$ in $\mathfrak{A}^*$.

First of all, it is impossible that $u \geq v$ in $\mathfrak{A}^*$ [999]. Consequently, we have $u \neq v$ (because otherwise, we would have $u = v$ and thus $u \geq v$ in $\mathfrak{A}^*$, which would contradict the fact that it is impossible that $u \geq v$ in $\mathfrak{A}^*$).

Let $m = \min\{\ell(u), \ell(v)\}$. Then, $m \leq \ell(u)$ and $m \leq \ell(v)$. Recall that $u = \left(u_1, u_2, \ldots, u_{\ell(u)}\right)$ and $v = \left(v_1, v_2, \ldots, v_{\ell(v)}\right)$. If every $i \in \{1, 2, \ldots, m\}$ satisfies $u_i = v_i$, then it is easy to see that $u < v$ in $\mathfrak{A}^*$ [1000]. Hence, for the rest of the proof of (13.146.1), we can WLOG assume that not every $i \in \{1, 2, \ldots, m\}$ satisfies $u_i = v_i$. Assume this.

Not every $i \in \{1, 2, \ldots, m\}$ satisfies $u_i = v_i$. In other words, there exists an $i \in \{1, 2, \ldots, m\}$ which does not satisfy $u_i = v_i$. Let k be the smallest such i. Thus, $k \in \{1, 2, \ldots, m\}$ does not satisfy $u_k = v_k$, whereas

$$\text{every } i \in \{1, 2, \ldots, m\} \text{ satisfying } i < k \text{ satisfies } u_i = v_i. \tag{13.146.4}$$

such that ($u_i < v_i$ in $\mathfrak{B}$, and every $j \in \{1, 2, \ldots, i-1\}$ satisfies $u_j = v_j$) (namely, $i = i'$). Thus,

$$\begin{aligned} &\textbf{either} \text{ there exists an } i \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\} \\ &\qquad \text{such that } \left(u_i < v_i \text{ in } \mathfrak{B}, \text{ and every } j \in \{1, 2, \ldots, i-1\} \text{ satisfies } u_j = v_j\right), \\ &\textbf{or} \text{ the word } u \text{ is a prefix of } v. \end{aligned}$$

In other words, $u \leq v$ in $\mathfrak{B}^*$. Thus, $u \leq v$ in $\mathfrak{B}^*$ is proven in Case 1.

Let us now consider Case 2. In this case, the word u is a prefix of v. Hence, $u \leq v$ in $\mathfrak{B}^*$. Thus, $u \leq v$ in $\mathfrak{B}^*$ is proven in Case 2.

Now, $u \leq v$ in $\mathfrak{B}^*$ is proven in each of the two Cases 1 and 2. Since these two Cases cover all possibilities, this yields that $u \leq v$ in $\mathfrak{B}^*$ always holds.

Now, let us forget that we fixed u and v. We have thus shown that any two elements u and v of $\mathfrak{A}^*$ satisfying $u \leq v$ in $\mathfrak{A}^*$ satisfy $u \leq v$ in $\mathfrak{B}^*$. Renaming the variables u and v as a and b in this statement, we conclude the following: Any two elements a and b of $\mathfrak{A}^*$ satisfying $a \leq b$ in $\mathfrak{A}^*$ satisfy $a \leq b$ in $\mathfrak{B}^*$. Qed.

[998] *Proof of (13.146.1):* Assume that $u < v$ in $\mathfrak{A}^*$. Thus, $u \neq v$ and $u \leq v$ in $\mathfrak{A}^*$. Let $\mathfrak{B}$ be a linear extension of $\mathfrak{A}$. Then, $\mathfrak{B}^*$ is an extension of the poset $\mathfrak{A}^*$ (by Proposition 13.146.3(a)). Hence, $u \leq v$ in $\mathfrak{B}^*$ (since $u \leq v$ in $\mathfrak{A}^*$). Combined with $u \neq v$, this yields $u < v$ in $\mathfrak{B}^*$.

Now, let us forget that we fixed $\mathfrak{B}$. We thus have proven that $u < v$ in $\mathfrak{B}^*$ for every linear extension $\mathfrak{B}$ of $\mathfrak{A}$. This proves (13.146.1).

[999] *Proof.* Assume the contrary. Thus, $u \geq v$ in $\mathfrak{A}^*$. Hence, $v \leq u$ in $\mathfrak{A}^*$.

Proposition 13.146.2(c) (applied to $P = \mathfrak{A}^*$) yields that there exists a linear extension of $\mathfrak{A}$. Let $\mathfrak{B}$ be such a linear extension. Then, $u < v$ in $\mathfrak{B}^*$ (by (13.146.3)). But $\mathfrak{B}^*$ is an extension of the poset $\mathfrak{A}^*$ (by Proposition 13.146.2(a)). Thus, $v \leq u$ in $\mathfrak{B}^*$ (since $v \leq u$ in $\mathfrak{A}^*$). This contradicts $u < v$ in $\mathfrak{B}^*$. This contradiction proves that our assumption was wrong, qed.

[1000] *Proof.* Assume that every $i \in \{1, 2, \ldots, m\}$ satisfies $u_i = v_i$. Thus, $(u_1, u_2, \ldots, u_m) = (v_1, v_2, \ldots, v_m)$.

Let us first assume (for the sake of contradiction) that $\ell(u) \geq \ell(v)$. Then, $m = \min\{\ell(u), \ell(v)\} = \ell(v)$ (since $\ell(u) \geq \ell(v)$). Now,

$$\begin{aligned} v &= \left(v_1, v_2, \ldots, v_{\ell(v)}\right) = (v_1, v_2, \ldots, v_m) \qquad (\text{since } \ell(v) = m) \\ &= (u_1, u_2, \ldots, u_m). \end{aligned}$$

But the word $(u_1, u_2, \ldots, u_m)$ is clearly a prefix of $\left(u_1, u_2, \ldots, u_{\ell(u)}\right)$ (since $m \leq \ell(u)$). In other words, the word v is a prefix of u (since $v = (u_1, u_2, \ldots, u_m)$ and $u = \left(u_1, u_2, \ldots, u_{\ell(u)}\right)$). Hence, $v \leq u$ in $\mathfrak{A}^*$. In other words, $u \geq v$ in $\mathfrak{A}^*$. This contradicts the fact that it is impossible that $u \geq v$ in $\mathfrak{A}^*$.

This contradiction proves that our assumption (that $\ell(u) \geq \ell(v)$) was wrong. Hence, we cannot have $\ell(u) \geq \ell(v)$. We thus have $\ell(u) < \ell(v)$. Thus, $m = \min\{\ell(u), \ell(v)\} = \ell(u)$ (since $\ell(u) < \ell(v)$). Now,

$$\begin{aligned} u &= \left(u_1, u_2, \ldots, u_{\ell(v)}\right) = (u_1, u_2, \ldots, u_m) \qquad (\text{since } \ell(u) = m) \\ &= (v_1, v_2, \ldots, v_m). \end{aligned}$$

But the word $(v_1, v_2, \ldots, v_m)$ is clearly a prefix of $\left(v_1, v_2, \ldots, v_{\ell(v)}\right)$ (since $m \leq \ell(v)$). In other words, the word u is a prefix of v (since $u = (v_1, v_2, \ldots, v_m)$ and $v = \left(v_1, v_2, \ldots, v_{\ell(v)}\right)$). Hence, $u \leq v$ in $\mathfrak{A}^*$. Combined with $u \neq v$, this yields that $u < v$ in $\mathfrak{A}^*$, qed.

We have $u_k \neq v_k$ (since k does not satisfy $u_k = v_k$). We must have $v_k \geq u_k$ in $\mathfrak{A}$ [1001]. That is, $u_k \leq v_k$ in $\mathfrak{A}$. Combined with $u_k \neq v_k$, this yields that $u_k < v_k$ in $\mathfrak{A}$.

Every $j \in \{1, 2, \ldots, k-1\}$ satisfies $u_j = v_j$ (by (13.146.4), applied to $i = j$). Also, we have $k \in \{1, 2, \ldots, m\} = \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$ (since $m = \min\{\ell(u), \ell(v)\}$). Altogether, we thus have shown that $k \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$ satisfies ($u_k < v_k$ in $\mathfrak{A}$, and every $j \in \{1, 2, \ldots, k-1\}$ satisfies $u_j = v_j$). Thus, there exists an $i \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$ such that
($u_i < v_i$ in $\mathfrak{A}$, and every $j \in \{1, 2, \ldots, i-1\}$ satisfies $u_j = v_j$) (namely, $i = k$). Hence,

either there exists an $i \in \{1, 2, \ldots, \min\{\ell(u), \ell(v)\}\}$
such that ($u_i < v_i$ in $\mathfrak{A}$, and every $j \in \{1, 2, \ldots, i-1\}$ satisfies $u_j = v_j$),
or the word u is a prefix of v.

In other words, $u < v$ in $\mathfrak{A}^*$ (by the definition of the relation $<$ on $\mathfrak{A}^*$). This proves (13.146.2).

Combining the implications (13.146.1) and (13.146.2), we obtain the following equivalence of statements:

$$(u < v \text{ in } \mathfrak{A}^*) \iff (u < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}).$$

Thus, Proposition 13.146.3(b) is proven. □

Let us now give a new proof of the fact that Corollary 6.1.6 holds in the partial-order setting:

Alternative proof of Corollary 6.1.6 in the partial-order setting. We need to prove that $uw \geq wu$. If $uw = wu$, then this is obvious. Hence, for the rest of this proof, we can WLOG assume that $uw \neq wu$. Assume this.

Let $\mathfrak{B}$ be any linear extension of the alphabet $\mathfrak{A}$. Then, $\mathfrak{B}^*$ is an extension of $\mathfrak{A}^*$ (according to Proposition 13.146.3(a)). Hence, $uv \geq vu$ in $\mathfrak{B}^*$ (since $uv \geq vu$ in $\mathfrak{A}^*$) and $vw \geq wv$ in $\mathfrak{B}^*$ (since $vw \geq wv$ in $\mathfrak{A}^*$). But the alphabet $\mathfrak{B}$ is totally ordered, and thus Corollary 6.1.6 (applied to $\mathfrak{B}$ instead of $\mathfrak{A}$) yields that $uw \geq wu$ in $\mathfrak{B}^*$ (since we know that Corollary 6.1.6 holds in the total-order setting). Thus, $uw > wu$ in $\mathfrak{B}^*$ (since $uw \neq wu$). In other words, $wu < uw$ in $\mathfrak{B}^*$.

Now, let us forget that we fixed $\mathfrak{B}$. We thus have shown that $wu < uw$ in $\mathfrak{B}^*$ for every linear extension $\mathfrak{B}$ of $\mathfrak{A}$. But Proposition 13.146.3(b) (applied to wu and uw instead of u and v) yields that $wu < uw$ holds in $\mathfrak{A}^*$ if and only if

$$(wu < uw \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}).$$

Thus, we conclude that $wu < uw$ holds in $\mathfrak{A}^*$ (since we already know that $wu < uw$ in $\mathfrak{B}^*$ for every linear extension $\mathfrak{B}$ of $\mathfrak{A}$). Thus, $uw > wu$ in $\mathfrak{A}^*$; hence, $uw \geq wu$ in $\mathfrak{A}^*$. This proves Corollary 6.1.6 in the partial-order setting. □

Next, let us give a new proof of the fact that Theorem 6.1.20 holds in the partial-order setting:

Alternative proof of Theorem 6.1.20 in the partial-order setting. We need to prove the equivalence $\mathcal{A} \iff \mathcal{B} \iff \mathcal{C} \iff \mathcal{D}$. We can prove the implications $\mathcal{A} \Longrightarrow \mathcal{B}$, $\mathcal{A} \Longrightarrow \mathcal{C}$, $\mathcal{A} \Longrightarrow \mathcal{D}$ and $\mathcal{B} \Longrightarrow \mathcal{A}$ in the same way as we did in the total-order setting. Hence, in order to prove Theorem 6.1.20, it will be enough to prove the implications $\mathcal{C} \Longrightarrow \mathcal{B}$ and $\mathcal{D} \Longrightarrow \mathcal{B}$.

Proof of the implication $\mathcal{C} \Longrightarrow \mathcal{B}$: Assume that Assertion $\mathcal{C}$ holds.

[1001] *Proof.* Assume the contrary. Thus, we don't have $v_k \geq u_k$ in $\mathfrak{A}$. Hence, Proposition 13.146.2(d) (applied to $P = \mathfrak{A}^*$, $a = v_k$ and $b = u_k$) yields that there exists a linear extension Q of $\mathfrak{A}$ such that we have $v_k < u_k$ in Q. Let $\mathfrak{B}$ be such a linear extension. Thus, $\mathfrak{B}$ is a linear extension of $\mathfrak{A}$ such that we have $v_k < u_k$ in $\mathfrak{B}$. We have $u < v$ in $\mathfrak{B}^*$ (by (13.146.3)).

Every $j \in \{1, 2, \ldots, k-1\}$ satisfies $u_j = v_j$ (by (13.146.4), applied to $i = j$). In other words, every $j \in \{1, 2, \ldots, k-1\}$ satisfies $v_j = u_j$. Also, we have $k \in \{1, 2, \ldots, m\} = \{1, 2, \ldots, \min\{\ell(v), \ell(u)\}\}$ (since $m = \min\{\ell(u), \ell(v)\} = \min\{\ell(v), \ell(u)\}$). Altogether, we thus have shown that $k \in \{1, 2, \ldots, \min\{\ell(v), \ell(u)\}\}$ satisfies ($v_k < u_k$ in $\mathfrak{B}$, and every $j \in \{1, 2, \ldots, k-1\}$ satisfies $v_j = u_j$). Thus, there exists an $i \in \{1, 2, \ldots, \min\{\ell(v), \ell(u)\}\}$ such that
($v_i < u_i$ in $\mathfrak{B}$, and every $j \in \{1, 2, \ldots, i-1\}$ satisfies $v_j = u_j$) (namely, $i = k$). Hence,

either there exists an $i \in \{1, 2, \ldots, \min\{\ell(v), \ell(u)\}\}$
such that ($v_i < u_i$ in $\mathfrak{B}$, and every $j \in \{1, 2, \ldots, i-1\}$ satisfies $v_j = u_j$),
or the word v is a prefix of u.

In other words, $v < u$ in $\mathfrak{B}^*$ (by the definition of the relation $<$ on $\mathfrak{B}^*$). This contradicts the fact that $u < v$ in $\mathfrak{B}^*$. This contradiction proves that our assumption was wrong, qed.

Let $\mathfrak{B}$ be any linear extension of the alphabet $\mathfrak{A}$. Then, $\mathfrak{B}^*$ is an extension of $\mathfrak{A}^*$ (according to Proposition 13.146.3(a)). It is easy to see that Assertion $\mathcal{C}$ (with $\mathfrak{A}$ replaced by $\mathfrak{B}$) holds[1002]. But we can apply Theorem 6.1.20 to $\mathfrak{B}$ instead of $\mathfrak{A}$ (since $\mathfrak{B}$ is totally ordered). As a consequence, we see that the four assertions $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$ and $\mathcal{D}$ (all with $\mathfrak{A}$ replaced by $\mathfrak{B}$) are equivalent. In particular, Assertion $\mathcal{C}$ (with $\mathfrak{A}$ replaced by $\mathfrak{B}$) is equivalent to Assertion $\mathcal{B}$ (with $\mathfrak{A}$ replaced by $\mathfrak{B}$). Since Assertion $\mathcal{C}$ (with $\mathfrak{A}$ replaced by $\mathfrak{B}$) holds, we thus conclude that Assertion $\mathcal{B}$ (with $\mathfrak{A}$ replaced by $\mathfrak{B}$) holds. In other words,

$$\text{any two nonempty words } u \in \mathfrak{B}^* \text{ and } v \in \mathfrak{B}^* \text{ satisfying } w = uv \text{ satisfy } v > w \text{ in } \mathfrak{B}^*. \tag{13.146.5}$$

Now, let $u \in \mathfrak{A}^*$ and $v \in \mathfrak{A}^*$ be two nonempty words satisfying $w = uv$. It is easy to see that

$$(w < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}) \tag{13.146.6}$$

[1003].

But Proposition 13.146.3(b) (applied to w instead of u) yields that $w < v$ holds in $\mathfrak{A}^*$ if and only if we have

$$(w < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A}).$$

Consequently, we conclude that $w < v$ holds in $\mathfrak{A}^*$ (since we know that we have $(w < v \text{ in } \mathfrak{B}^* \text{ for every linear extension } \mathfrak{B} \text{ of } \mathfrak{A})$). In other words, $v > w$ in $\mathfrak{A}^*$.

Now, let us forget that we fixed u and v. We have thus shown that any nonempty words $u \in \mathfrak{A}^*$ and $v \in \mathfrak{A}^*$ satisfying $w = uv$ satisfy $v > w$ in $\mathfrak{A}^*$. In other words, Assertion $\mathcal{B}$ holds. Thus, we have proven the implication $\mathcal{C} \Longrightarrow \mathcal{B}$.

Proof of the implication $\mathcal{D} \Longrightarrow \mathcal{B}$: The proof of the implication $\mathcal{D} \Longrightarrow \mathcal{B}$ is analogous to our above proof of the implication $\mathcal{C} \Longrightarrow \mathcal{B}$, and thus left to the reader.

The proof of Theorem 6.1.20 in the partial-order setting is complete. □

The examples of Theorem 6.1.20 and Corollary 6.1.6 should have illustrated how Proposition 13.146.3 allows deriving certain facts about the partial-order setting from the corresponding facts about the total-order setting. This trick, however, has its limits. For example, in the total-order setting, the fact that any Lyndon word w of length > 1 can be written in the form $w = uv$ for two Lyndon words u and v satisfying $u < w < v$ is a consequence of Theorem 6.1.30. But in the partial-order setting, it is not clear how to derive it from the total-order setting, although it **is** true in the partial-order setting (and follows from Exercise 6.1.31).]

(d) If $\mathfrak{A}$ is the partially ordered alphabet $\{1, 2\}$ with no relations whatsoever (i.e., a 2-element antichain), and w is the word 12, then w does satisfy (if $w \leq t^n$, then $w \leq t$) for every nonempty word t and every positive integer n, but w is not Lyndon.

[*Remark:* One direction of Exercise 6.1.22 does hold in the partial-order setting: Namely, if w is Lyndon, then every nonempty word t and every positive integer n satisfy (if $w \leq t^n$, then $w \leq t$). The proof of this is the same as in the total-order setting.]

(e) The following statement is clearly equivalent to Exercise 6.1.22 in the total-order setting, while still being valid in the partial-order setting:

Proposition 13.146.4. *Let w be a nonempty word. Then, w is Lyndon if and only if every nonempty word t and every positive integer n satisfy (if $w > t$, then $w > t^n$).*

Proof of Proposition 13.146.4 in the partial-order setting. Let us first assume that w is Lyndon. We shall prove that

$$(\text{every nonempty word } t \text{ and every positive integer } n \text{ satisfy (if } w > t, \text{ then } w > t^n)). \tag{13.146.7}$$

[1002] *Proof.* Let $u \in \mathfrak{B}^*$ and $v \in \mathfrak{B}^*$ be two nonempty words satisfying $w = uv$. We have $u \in \mathfrak{B}^* = \mathfrak{A}^*$ and $v \in \mathfrak{B}^* = \mathfrak{A}^*$, and thus $u \in \mathfrak{A}^*$ and $v \in \mathfrak{A}^*$ are two nonempty words satisfying $w = uv$. Hence, we have $v > u$ in $\mathfrak{A}^*$ (since we assumed that Assertion $\mathcal{C}$ holds). Thus, $u < v$ in $\mathfrak{A}^*$, so that $u \neq v$ and $u \leq v$ in $\mathfrak{A}^*$.

So we have $u \leq v$ in $\mathfrak{A}^*$. Hence, $u \leq v$ in $\mathfrak{B}^*$ (since $\mathfrak{B}^*$ is an extension of $\mathfrak{A}^*$). Since $u \neq v$, this becomes $u < v$ in $\mathfrak{B}^*$. In other words, $v > u$ in $\mathfrak{B}^*$.

Now, let us forget that we fixed u and v. We thus have shown that any nonempty words $u \in \mathfrak{B}^*$ and $v \in \mathfrak{B}^*$ satisfying $w = uv$ satisfy $v > u$ in $\mathfrak{B}^*$. In other words, Assertion $\mathcal{C}$ (with $\mathfrak{A}$ replaced by $\mathfrak{B}$) holds

[1003] *Proof.* Let $\mathfrak{B}$ be a linear extension of $\mathfrak{A}$. Then, $\mathfrak{B}^*$ is an extension of $\mathfrak{A}^*$ (according to Proposition 13.146.3(a)). Thus, $\mathfrak{B}^* = \mathfrak{A}^*$ as sets, so that $u \in \mathfrak{A}^* = \mathfrak{B}^*$ and $v \in \mathfrak{A}^* = \mathfrak{B}^*$. Now, (13.146.5) yields $v > w$ in $\mathfrak{B}^*$. In other words, $w < v$ in $\mathfrak{B}^*$. This proves (13.146.6).

Let t be a nonempty word, and let n be a positive integer. Assume that $w > t$. We need to prove that $w > t^n$.

Assume the contrary. Thus, we don't have $w > t^n$. Thus, there exists an $i \in \{1, 2, \ldots, n\}$ such that we don't have $w > t^i$ (namely, $i = n$). Let m be the **minimal** such i. Thus, $m \in \{1, 2, \ldots, n\}$, and we don't have $w > t^m$. Hence, $m \neq 1$ (since we don't have $w > t^m$, but we do have $w > t = t^1$). Thus, $m \geq 2$, so that $m - 1$ is also an element of $\{1, 2, \ldots, n\}$. If we did not have $w > t^{m-1}$, then $m - 1$ would therefore be an $i \in \{1, 2, \ldots, n\}$ such that we don't have $w > t^i$. But this would contradict the fact that m is the **minimal** such i. Thus, we must have $w > t^{m-1}$. In other words, $t^{m-1} < w$.

Notice that $m - 1 \geq 1$ (since $m \geq 2$). Hence, the word t^{m-1} is nonempty (since t is nonempty). In other words, $t^{m-1} \neq \varnothing$.

Recall that we don't have $w > t^m$. It is now easy to see that we don't have $t^m \leq w$ [1004]. In other words, we don't have $t^{m-1}t \leq w\varnothing$ (since $t^m = t^{m-1}t$ and $w = w\varnothing$).

But recall that $t^{m-1} < w$. Hence, Proposition 6.1.2(d) (applied to $a = t^{m-1}$, $b = t$, $c = w$ and $d = \varnothing$) yields that either we have $t^{m-1}t \leq w\varnothing$ or the word t^{m-1} is a prefix of w. Thus, the word t^{m-1} is a prefix of w (since we don't have $t^{m-1}t \leq w\varnothing$). In other words, there exists a $v \in \mathfrak{A}^*$ such that $w = t^{m-1}v$. Consider this v. We have $v \neq \varnothing$ (because otherwise, we would have $v = \varnothing$ and thus $w = t^{m-1}\underbrace{v}_{=\varnothing} = t^{m-1}$, contradicting the fact that $w > t^{m-1}$), so that v is nonempty. Hence, Proposition 6.1.14(b) (applied to $u = t^{m-1}$) now yields $v > t^{m-1}$. Hence, $t^{m-1} < v$. Thus, Proposition 6.1.2(b) (applied to $a = t^{m-1}$, $c = t^{m-1}$ and $d = v$) yields $t^{m-1}t^{m-1} \leq t^{m-1}v = w$. Hence,

$$\begin{aligned} w &\geq t^{m-1}t^{m-1} = t^{2(m-1)} = t^{m+(m-2)} = t^m t^{m-2} \qquad \text{(this makes sense since } m \geq 2\text{)} \\ &\geq t^m \qquad \left(\text{since } t^m \text{ is a prefix of } t^m t^{m-2}\right). \end{aligned}$$

Hence, $t^m \leq w$. This contradicts the fact that we don't have $t^m \leq w$. This contradiction proves that our assumption (that we don't have $w > t^n$) was false. Hence, $w > t^n$.

Forget now that we assumed that $w > t$. We thus have proven that if $w > t$, then $w > t^n$.

Now, forget that we fixed t and assumed that w is Lyndon. We thus have shown that

$$\text{(if } w \text{ is Lyndon, then (13.146.7) holds)}. \tag{13.146.8}$$

Now, conversely, assume that (13.146.7) holds. We will prove that w is Lyndon.

Let u and v be any nonempty words satisfying $w = uv$. We have $w \neq u$ [1005]. Combined with $w = uv \geq u$ (since u is a prefix of uv), this yields $w > u$. But (13.146.7) (applied to $t = u$ and $n = 2$) yields that if $w > u$, then $w > u^2$. Hence, $w > u^2$ (since we know that $w > u$). Thus, $uv = w > u^2 = uu$, so that $uu < uv$. Thus, Proposition 6.1.2(c) (applied to $a = u$, $c = u$ and $d = v$) yields $u \leq v$. Since $u \neq v$ [1006], this becomes $u < v$, so that $v > u$.

Now, let us forget that we fixed u and v. We thus have proven that any nonempty words u and v satisfying $w = uv$ satisfy $v > u$. In other words, Assertion $\mathcal{C}$ of Theorem 6.1.20 holds. Hence, Assertion $\mathcal{A}$ of Theorem 6.1.20 holds as well (since Theorem 6.1.20 yields that these Assertions $\mathcal{C}$ and $\mathcal{A}$ are equivalent). In other words, the word w is Lyndon.

Now, forget that we fixed w. We thus have proven that

$$\text{(if (13.146.7) holds, then } w \text{ is Lyndon)}.$$

Combined with (13.146.8), this yields that w is Lyndon if and only if (13.146.7) holds. This proves Proposition 13.146.4. □

[1004] *Proof.* Assume the contrary. Thus, we have $t^m \leq w$. Hence, $w \geq t^m$, so that $w = t^m$ (since we don't have $w > t^m$). Thus, $w = t^m = t^{m-1}t$. Thus, t is a suffix of w. Thus, Corollary 6.1.15 (applied to t instead of v) yields $t \geq w$. Thus, $t \geq w = t^m = tt^{m-1}$. Combined with $tt^{m-1} \geq t$ (since t is a prefix of tt^{m-1}), this yields $t = tt^{m-1}$. Thus, $tt^{m-1} = t = t\varnothing$. Cancelling t from this equality, we obtain $t^{m-1} = \varnothing$. This contradicts $t^{m-1} \neq \varnothing$. This contradiction proves that our assumption was wrong, qed.

[1005] *Proof.* Assume the contrary. Then, $w = u$. Hence, $uv = w = u = u\varnothing$. Cancelling u from this equality, we obtain $v = \varnothing$, so that v is empty. This contradicts the fact that v is nonempty. This contradiction proves that our assumption was wrong, qed.

[1006] *Proof.* Assume the contrary. Then, $u = v$. Hence, $w = u\underbrace{v}_{=u} = uu = u^2$. This contradicts $w > u^2$. This contradiction proves that our assumption was wrong, qed.

Thus, we have salvaged Exercise 6.1.22 in the partial-order setting. (And, as a side effect, we have obtained an alternative solution for Exercise 6.1.22 in the total-order setting.)

[*Remark:* Speaking of salvaging, there is a little piece of Proposition 6.1.19 which can be salvaged for the partial-order case:

Proposition 13.146.5. *Let w be a nonempty word. Let v be a (lexicographically) minimal nonempty suffix of w* [1007]*. Then, there exists a $u \in \mathfrak{A}^*$ such that $w = uv$ but we don't have $uv < vu$.*

Proof of Proposition 13.146.5 in the partial-order case. We know that v is a suffix of w. Hence, there exists a $u \in \mathfrak{A}^*$ such that $w = uv$. Consider this u. It will clearly be enough to show that we don't have $uv < vu$.

So let us prove that we don't have $uv < vu$. Indeed, assume the contrary. Then, $uv < vu$. Thus, there exists at least one suffix t of u such that $tv < vt$ (namely, $t = u$). Let p be the **minimum-length** such suffix. Then, $pv < vp$. Thus, p is nonempty. In other words, $p \neq \varnothing$.

Since p is a suffix of u, it is clear that pv is a suffix of $uv = w$. So we know that pv is a nonempty suffix of w. Since v is a minimal such suffix, this yields that we don't have $pv < v$. Hence, we don't have $pv \leq v$ [1008].

But $pv\varnothing = pv < vp$. Hence, Proposition 6.1.2(e) (applied to $a = pv$, $b = \varnothing$, $c = v$ and $d = p$) yields that either we have $pv \leq v$ or the word v is a prefix of pv. Thus, the word v is a prefix of pv (since we don't have $pv \leq v$). In other words, there exists a $q \in \mathfrak{A}^*$ such that $pv = vq$. Consider this q. This q is nonempty (because otherwise we would have $pv = v \underbrace{q}_{=\varnothing} = v$, contradicting the fact that p is nonempty). From $vq = pv < vp$, we obtain $q \leq p$ (by Proposition 6.1.2(c), applied to $a = v$, $c = q$ and $d = p$).

We know that q is a suffix of pv (since $vq = pv$), whereas pv is a suffix of w. Thus, q is a suffix of w. So q is a nonempty suffix of w. Since v is a minimal such suffix, this yields that we don't have $q < v$. But we have $p\varnothing = p \leq pv < vp$. Hence, Proposition 6.1.2(e) (applied to $a = p$, $b = \varnothing$, $c = v$ and $d = p$) yields that either we have $p \leq v$ or the word v is a prefix of p. From this, it is easy to obtain that v is a prefix of p [1009]. In other words, there exists an $r \in \mathfrak{A}^*$ such that $p = vr$. Consider this r. Clearly, r is a suffix of p, while p is a suffix of u; therefore, r is a suffix of u. Also, $pv < vp$ rewrites as $vrv < vvr$ (because $p = vr$). Thus, Proposition 6.1.2(c) (applied to $a = v$, $c = rv$ and $d = vr$) yields $rv \leq vr$. Since $rv \neq vr$ (because otherwise, we would have $rv = vr$, thus $v \underbrace{rv}_{=vr} = vvr$, contradicting $vrv < vvr$), this becomes $rv < vr$.

The word v is nonempty; thus, $\ell(v) > 0$.

Now, r is a suffix of u such that $rv < vr$. Since p is the minimum-length such suffix, this yields $\ell(r) \geq \ell(p)$. But this contradicts the fact that $\ell\left(\underbrace{p}_{=vr}\right) = \ell(vr) = \underbrace{\ell(v)}_{>0} + \ell(r) > \ell(r)$. This contradiction proves our assumption wrong. Thus, we have proven that we don't have $uv < vu$. This completes the proof of Proposition 13.146.5 in the partial-order case. □

]

(f) Let us first establish a lemma which plays a role similar to that of Lemma 6.1.28 in the total-order setting:

Lemma 13.146.6. *Let $(a_1, a_2, \ldots, a_k)$ be a Hazewinkel-CFL factorization of a nonempty word w (in the partial-order setting). Let p be a suffix of w such that p is Lyndon. Then, $p \geq a_k$.*

[1007] By this, we mean that:

- v is a nonempty suffix of w;
- no nonempty suffix s of w satisfies $s < v$.

Such a v always exists (since w is nonempty), but is not always unique.

[1008] *Proof.* Assume the contrary. Thus, $pv \leq v$. This yields that $pv = v$ (since we don't have $pv < v$). Thus, $pv = v = \varnothing v$. Cancelling v from this equation, we obtain $p = \varnothing$. This contradicts $p \neq \varnothing$. This contradiction proves that our assumption was wrong, qed.

[1009] *Proof.* Assume the contrary. Thus, v is not a prefix of p. Hence, $p \leq v$ (since either we have $p \leq v$ or the word v is a prefix of p). Now, $q \leq p \leq v$. Now, $q = v$ (since $q \leq v$ but not $q < v$). Hence, $v = q \leq p$. Combined with $p \leq v$, this yields $v = p$. Hence, $p \underbrace{v}_{=p} = \underbrace{p}_{=v} p = vp$, which contradicts $pv < vp$. This contradiction proves that our assumption was wrong, qed.

Proof of Lemma 13.146.6. We will prove Lemma 13.146.6 by induction over the (obviously) positive integer k.

Induction base: Assume that $k = 1$. By the definition of a Hazewinkel-CFL factorization, $(a_1, a_2, \ldots, a_k)$ is a tuple of Lyndon words satisfying $w = a_1 a_2 \cdots a_k$ (since $(a_1, a_2, \ldots, a_k)$ is a Hazewinkel-CFL factorization of w). Thus, $w = a_1 a_2 \cdots a_k = a_1$ (since $k = 1$), so that w is a Lyndon word (since a_1 is a Lyndon word). But p is nonempty (since p is Lyndon). Thus, Corollary 6.1.15 (applied to $v = p$) yields $p \geq w = a_1 = a_k$ (since $1 = k$). Thus, Lemma 13.146.6 is proven in the case $k = 1$. The induction base is complete.

Induction step: Let K be a positive integer. Assume (as the induction hypothesis) that Lemma 13.146.6 is proven for $k = K$. We now need to show that Lemma 13.146.6 holds for $k = K + 1$.

So let $(a_1, a_2, \ldots, a_{K+1})$ be a Hazewinkel-CFL factorization of a nonempty word w. Let p be a nonempty suffix of w such that p is Lyndon. We need to prove that $p \geq a_{K+1}$.

The tuple $(a_1, a_2, \ldots, a_{K+1})$ is a Hazewinkel-CFL factorization of w. By the definition of a Hazewinkel-CFL factorization, this yields that $(a_1, a_2, \ldots, a_{K+1})$ is a tuple of Lyndon words such that $w = a_1 a_2 \cdots a_{K+1}$ and such that no $i \in \{1, 2, \ldots, K\}$ satisfies $a_i < a_{i+1}$.

Let $w' = a_2 a_3 \cdots a_{K+1}$; then, $w = a_1 a_2 \cdots a_{K+1} = a_1 \underbrace{(a_2 a_3 \cdots a_{K+1})}_{=w'} = a_1 w'$. Hence, every nonempty suffix of w is either a nonempty suffix of w', or has the form qw' for a nonempty suffix q of a_1. Since p is a nonempty suffix of w, we thus must be in one of the following two cases:

Case 1: The word p is a nonempty suffix of w'.

Case 2: The word p has the form qw' for a nonempty suffix q of a_1.

Let us first consider Case 1. In this case, p is a nonempty suffix of w'. The K-tuple $(a_2, a_3, \ldots, a_{K+1})$ of Lyndon words satisfies $w' = a_2 a_3 \cdots a_{K+1}$ and has the property that no $i \in \{1, 2, \ldots, K-1\}$ satisfies $a_{i+1} < a_{(i+1)+1}$ [1010]. Therefore, $(a_2, a_3, \ldots, a_{K+1})$ is a Hazewinkel-CFL factorization of w'. We can thus apply Lemma 13.146.6 to K, w' and $(a_2, a_3, \ldots, a_{K+1})$ instead of k, w and $(a_1, a_2, \ldots, a_k)$ (because we assumed that Lemma 13.146.6 is proven for $k = K$). As a result, we obtain that $p \geq a_{K+1}$. Thus, $p \geq a_{K+1}$ is proven in Case 1.

Let us now consider Case 2. In this case, p has the form qw' for a nonempty suffix q of a_1. Consider this q. Since a_1 is a Lyndon word, we have $q \geq a_1$ (by Corollary 6.1.15, applied to a_1 and q instead of w and v). Our goal, however, is to prove that $q \geq a_{K+1}$.

We will show that

$$q \geq a_i \qquad \text{for every } i \in \{1, 2, \ldots, K+1\}. \tag{13.146.9}$$

Proof of (13.146.9): We will prove (13.146.9) by induction over i:

Induction base: We know that $q \geq a_1$. In other words, (13.146.9) holds for $i = 1$. This completes the induction base.

Induction step: Let $j \in \{1, 2, \ldots, K\}$. Assume that (13.146.9) holds for $i = j$. We must prove that (13.146.9) holds for $i = j + 1$.

We have $j \leq K$. Hence, the product $a_{j+1} a_{j+2} \cdots a_{K+1}$ contains at least one factor. Also, the factors of this product are nonempty words (because the words a_{j+1}, a_{j+2}, $\ldots$, a_{K+1} are nonempty (since these words are Lyndon)). Hence, $a_{j+1} a_{j+2} \cdots a_{K+1}$ is a nonempty product of nonempty words. Consequently, $a_{j+1} a_{j+2} \cdots a_{K+1}$ is a nonempty word.

The product $a_{j+2} a_{j+3} \cdots a_{K+1}$ is well-defined (because $j \leq K$). Denote this product by g. Thus, $g = a_{j+2} a_{j+3} \cdots a_{K+1}$.

We have $q \geq a_j$ (since (13.146.9) holds for $i = j$). But

$$p = q \underbrace{\underbrace{w'}_{= a_2 a_3 \cdots a_{K+1}}}_{= (a_2 a_3 \cdots a_j)(a_{j+1} a_{j+2} \cdots a_{K+1})} = q (a_2 a_3 \cdots a_j)(a_{j+1} a_{j+2} \cdots a_{K+1}) = (q (a_2 a_3 \cdots a_j))(a_{j+1} a_{j+2} \cdots a_{K+1}).$$

[1010] *Proof.* We already know that $w' = a_2 a_3 \cdots a_{K+1}$. It remains to show that no $i \in \{1, 2, \ldots, K-1\}$ satisfies $a_{i+1} < a_{(i+1)+1}$.

To prove this, let us assume this contrary. Thus, there exists an $i \in \{1, 2, \ldots, K-1\}$ satisfying $a_{i+1} < a_{(i+1)+1}$. Let j be such an i. Then, $j \in \{1, 2, \ldots, K-1\}$ satisfies $a_{j+1} < a_{(j+1)+1}$. Hence, we have $a_i < a_{i+1}$ for $i = j + 1$. This contradicts the fact that no $i \in \{1, 2, \ldots, K\}$ satisfies $a_i < a_{i+1}$. This contradiction shows that our assumption was wrong, qed.

Consequently, $a_{j+1}a_{j+2}\cdots a_{K+1}$ is a suffix of p. Thus, Corollary 6.1.15 (applied to p and $a_{j+1}a_{j+2}\cdots a_{K+1}$ instead of w and v) yields $a_{j+1}a_{j+2}\cdots a_{K+1} \geq p$ (since p is Lyndon). Thus,

$$a_{j+1}a_{j+2}\cdots a_{K+1} \geq p = qw' \geq q \geq a_j.$$

In other words,

$$a_j \leq a_{j+1}a_{j+2}\cdots a_{K+1} = a_{j+1}\underbrace{(a_{j+2}a_{j+3}\cdots a_{K+1})}_{=g} = a_{j+1}g.$$

Hence, $a_j\varnothing = a_j \leq a_{j+1}g$. Proposition 6.1.2(e) (applied to a_j, $\varnothing$, a_{j+1} and g instead of a, b, c and d) thus yields that either we have $a_j \leq a_{j+1}$ or the word a_{j+1} is a prefix of a_j. From this, it is easy to conclude that the word a_{j+1} is a prefix of a_j [1011]. Consequently, $a_{j+1} \leq a_j$, so that $a_j \geq a_{j+1}$ and $q \geq a_j \geq a_{j+1}$. In other words, (13.146.9) holds for $i = j+1$. This completes the induction step. Thus, (13.146.9) is proven by induction.

Now, (13.146.9) (applied to $i = K+1$) yields $q \geq a_{K+1}$. Hence, $p = qw' \geq q \geq a_{K+1}$. Thus, $p \geq a_{K+1}$ is proven in Case 2.

We have now proven $p \geq a_{K+1}$ in all cases. This proves that Lemma 13.146.6 holds for $k = K+1$. The induction step is thus finished, and with it the proof of Lemma 13.146.6. □

We can now conclude the solution of Exercise 6.1.33(f) by proving the following proposition:

Proposition 13.146.7. *Let w be a word (in the partial-order setting). Then, there exists a unique Hazewinkel-CFL factorization of w.*

The proof is an almost literal adaptation of the proof of Theorem 6.1.27:

Proof of Proposition 13.146.7. Let us first prove that there exists a Hazewinkel-CFL factorization of w.

Indeed, there clearly exists a tuple $(a_1, a_2, \ldots, a_k)$ of Lyndon words satisfying $w = a_1a_2\cdots a_k$ [1012]. Fix such a tuple with **minimum** k. We claim that no $i \in \{1, 2, \ldots, k-1\}$ satisfies $a_i < a_{i+1}$.

Indeed, if some $i \in \{1, 2, \ldots, k-1\}$ would satisfy $a_i < a_{i+1}$, then the word a_ia_{i+1} would be Lyndon (by Proposition 6.1.16(a), applied to $u = a_i$ and $v = a_{i+1}$), whence $(a_1, a_2, \ldots, a_{i-1}, a_ia_{i+1}, a_{i+2}, a_{i+3}, \ldots, a_k)$ would also be a tuple of Lyndon words satisfying $w = a_1a_2\cdots a_{i-1}(a_ia_{i+1})a_{i+2}a_{i+3}\cdots a_k$ but having length $k-1 < k$, contradicting the fact that k is the minimum length of such a tuple. Hence, no $i \in \{1, 2, \ldots, k-1\}$ can satisfy $a_i < a_{i+1}$. Thus, $(a_1, a_2, \ldots, a_k)$ is a Hazewinkel-CFL factorization of w, so we have shown that such a Hazewinkel-CFL factorization exists.

It remains to show that there exists at most one Hazewinkel-CFL factorization of w. We shall prove this by induction over $\ell(w)$. Thus, we fix a word w and assume that

(13.146.10)

$$\text{for every word } v \text{ with } \ell(v) < \ell(w), \text{ there exists at most one Hazewinkel-CFL factorization of } v.$$

We now have to prove that there exists at most one Hazewinkel-CFL factorization of w.

Indeed, let $(a_1, a_2, \ldots, a_k)$ and $(b_1, b_2, \ldots, b_m)$ be two Hazewinkel-CFL factorizations of w. We need to prove that $(a_1, a_2, \ldots, a_k) = (b_1, b_2, \ldots, b_m)$. If w is empty, then this is obvious, so we WLOG assume that it is not; thus, $k > 0$ and $m > 0$.

The tuple $(a_1, a_2, \ldots, a_k)$ is a Hazewinkel-CFL factorization of w. Thus, $(a_1, a_2, \ldots, a_k)$ is a tuple of Lyndon words satisfying $w = a_1a_2\cdots a_k$ and such that no $i \in \{1, 2, \ldots, k-1\}$ satisfies $a_i < a_{i+1}$.

The tuple $(b_1, b_2, \ldots, b_m)$ is a Hazewinkel-CFL factorization of w. Thus, $(b_1, b_2, \ldots, b_m)$ is a tuple of Lyndon words satisfying $w = b_1b_2\cdots b_m$ and such that no $i \in \{1, 2, \ldots, m-1\}$ satisfies $b_i < b_{i+1}$. Now, b_m is a suffix of w (since $w = b_1b_2\cdots b_m$). Also, b_m is Lyndon. Thus, Lemma 13.146.6 (applied to $p = b_m$) yields $b_m \geq a_k$. The same argument (but with the roles of $(a_1, a_2, \ldots, a_k)$ and $(b_1, b_2, \ldots, b_m)$ switched) shows that $a_k \geq b_m$. Combined with $b_m \geq a_k$, this yields $a_k = b_m$. Now let $v = a_1a_2\cdots a_{k-1}$. Then, $(a_1, a_2, \ldots, a_{k-1})$ is a tuple of Lyndon words satisfying $v = a_1a_2\cdots a_{k-1}$ and such that no $i \in \{1, 2, \ldots, (k-1)-1\}$ satisfies

[1011] *Proof.* Assume the contrary. Thus, the word a_{j+1} is not a prefix of a_j. Hence, we have $a_j \leq a_{j+1}$ (because we know that either we have $a_j \leq a_{j+1}$ or the word a_{j+1} is a prefix of a_j). Since we cannot have $a_j < a_{j+1}$ (because no $i \in \{1, 2, \ldots, K\}$ satisfies $a_i < a_{i+1}$), this yields that we have $a_j = a_{j+1}$. Therefore, a_{j+1} is a prefix of a_j; this contradicts our assumption that the word a_{j+1} is not a prefix of a_j. This contradiction proves that our assumption was wrong, qed.

[1012] For instance, the tuple $(w_1, w_2, \ldots, w_{\ell(w)})$ of one-letter words is a valid example (recall that one-letter words are always Lyndon).

$a_i < a_{i+1}$ (because no $i \in \{1, 2, \ldots, k-1\}$ satisfies $a_i < a_{i+1}$). In other words, $(a_1, a_2, \ldots, a_{k-1})$ is a Hazewinkel-CFL factorization of v.

But $w = a_1 a_2 \cdots a_k = \underbrace{a_1 a_2 \cdots a_{k-1}}_{=v} \underbrace{a_k}_{=b_m} = v b_m$, so that

$$v b_m = w = b_1 b_2 \cdots b_m = b_1 b_2 \cdots b_{m-1} b_m.$$

Cancelling b_m from this equality yields $v = b_1 b_2 \cdots b_{m-1}$. Thus, $(b_1, b_2, \ldots, b_{m-1})$ is a tuple of Lyndon words satisfying $v = b_1 b_2 \cdots b_{m-1}$ and such that no $i \in \{1, 2, \ldots, (m-1)-1\}$ satisfies $b_i < b_{i+1}$ (since no $i \in \{1, 2, \ldots, m-1\}$ satisfies $b_i < b_{i+1}$). In other words, $(b_1, b_2, \ldots, b_{m-1})$ is a Hazewinkel-CFL factorization of v. Since $\ell(v) < \ell(w)$ (because $v = a_1 a_2 \cdots a_{k-1}$ is shorter than $w = a_1 a_2 \cdots a_k$), we can apply (13.146.10) to obtain that there exists at most one Hazewinkel-CFL factorization of v. But we already know two such Hazewinkel-CFL factorizations: $(a_1, a_2, \ldots, a_{k-1})$ and $(b_1, b_2, \ldots, b_{m-1})$. Thus, $(a_1, a_2, \ldots, a_{k-1}) = (b_1, b_2, \ldots, b_{m-1})$. Combining this with $a_k = b_m$, we obtain $(a_1, a_2, \ldots, a_k) = (b_1, b_2, \ldots, b_m)$. This is exactly what we needed to prove. So we have shown (by induction) that there exists at most one Hazewinkel-CFL factorization of w. This completes the proof of Proposition 13.146.7. □

(g) *Solution to Exercise 6.1.32 in the partial-order setting.* Let us first observe the following fact (in the partial-order setting): If h is a nonempty word which is not a Lyndon word, then

(13.146.11) there exist nonempty words u and v such that $h = uv$ and not $vu > uv$.

[1013] Renaming u and v as p and q in this result, we obtain the following: If h is a nonempty word which is not a Lyndon word, then

(13.146.12) there exist nonempty words p and q such that $h = pq$ and not $qp > pq$.

Furthermore, if h is a nonempty word which is not a Lyndon word, then

(13.146.13) there exist nonempty words u and v such that $h = uv$ and not $v > u$.

[1014]

Now, let us come to the solution of Exercise 6.1.32 in the partial-order setting.

Solution to Exercise 6.1.32(a) in the partial-order setting. The implication $\mathcal{A}' \Longrightarrow \mathcal{D}'$ can be proven in the same way as it was proven in the total-order setting.

Let us now prove the implication $\mathcal{D}' \Longrightarrow \mathcal{A}'$:

Proof of the implication $\mathcal{D}' \Longrightarrow \mathcal{A}'$: Assume that Assertion $\mathcal{D}'$ holds. Thus, if u and v are nonempty words satisfying $w = uv$, then we have $vu \geq uv$.

We need to prove that Assertion $\mathcal{A}'$ holds, i.e., that w is a power of a Lyndon word. Assume the contrary. Thus, w is not a power of a Lyndon word; hence, w is not a Lyndon word itself. Consequently, (13.146.11) (applied to $h = w$) shows that there exist nonempty words u and v such that $w = uv$ and not $vu > uv$.

[1013] *Proof of (13.146.11):* Let h be a nonempty word which is not a Lyndon word. We need to prove that (13.146.11) holds.

In fact, assume the contrary. Then, there exist no nonempty words u and v such that $h = uv$ and not $vu > uv$. In other words, any nonempty words u and v satisfying $h = uv$ must satisfy $vu > uv$. In other words, Assertion $\mathcal{D}$ of Theorem 6.1.20 (with h instead of w) holds.

But we know (from Exercise 6.1.33(c)) that Theorem 6.1.20 holds in the partial-order setting. Hence, we can apply Theorem 6.1.20 to h instead of w. We thus conclude that Assertions $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$ and $\mathcal{D}$ of Theorem 6.1.20 (with h instead of w) are equivalent. Hence, Assertion $\mathcal{A}$ of Theorem 6.1.20 (with h instead of w) holds (since Assertion $\mathcal{D}$ of Theorem 6.1.20 (with h instead of w) holds). In other words, the word h is Lyndon. This contradicts the fact that the word h is not Lyndon. This contradiction shows that our assumption was wrong. Hence, (13.146.11) is proven, qed.

[1014] *Proof of (13.146.13):* Let h be a nonempty word which is not a Lyndon word. We need to prove that (13.146.13) holds.

In fact, assume the contrary. Then, there exist no nonempty words u and v such that $h = uv$ and not $v > u$. In other words, any nonempty words u and v satisfying $h = uv$ must satisfy $v > u$. In other words, Assertion $\mathcal{C}$ of Theorem 6.1.20 (with h instead of w) holds.

But we know (from Exercise 6.1.33(c)) that Theorem 6.1.20 holds in the partial-order setting. Hence, we can apply Theorem 6.1.20 to h instead of w. We thus conclude that Assertions $\mathcal{A}$, $\mathcal{B}$, $\mathcal{C}$ and $\mathcal{D}$ of Theorem 6.1.20 (with h instead of w) are equivalent. Hence, Assertion $\mathcal{A}$ of Theorem 6.1.20 (with h instead of w) holds (since Assertion $\mathcal{C}$ of Theorem 6.1.20 (with h instead of w) holds). In other words, the word h is Lyndon. This contradicts the fact that the word h is not Lyndon. This contradiction shows that our assumption was wrong. Hence, (13.146.13) is proven, qed.
